Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

ExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vs1sconvexec1d(task, y, ystride, z, zstride)
status = vs1dconvexec1d(task, y, ystride, z, zstride)
status = vs1cconvexec1d(task, y, ystride, z, zstride)
status = vs1zconvexec1d(task, y, ystride, z, zstride)
status = vs1scorrexec1d(task, y, ystride, z, zstride)
status = vs1dcorrexec1d(task, y, ystride, z, zstride)
status = vs1ccorrexec1d(task, y, ystride, z, zstride)
status = vs1zcorrexec1d(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX1D(task, y, ystride, z, zstride);
status = vsldConvExecX1D(task, y, ystride, z, zstride);
status = vslcConvExecX1D(task, y, ystride, z, zstride);
status = vslzConvExecX1D(task, y, ystride, z, zstride);
status = vslsCorrExecX1D(task, y, ystride, z, zstride);
status = vslcCorrExecX1D(task, y, ystride, z, zstride);
status = vslzCorrExecX1D(task, y, ystride, z, zstride);
status = vsldCorrExecX1D(task, y, ystride, z, zstride);
```

Input Parameters

Name	Type	Description
<i>task</i>	<p>FORTRAN 77: INTEGER*4</p> <p>task(2) for vslsconvexecx1d, vsldconvexecx1d, vslcconvexecx1d, vslzconvexecx1d</p> <p>INTEGER*4 task(2) for vslscorreexecx1d, vsldcorreexecx1d, vslccorreexecx1d, vslzcorreexecx1d</p> <p>Fortran 90: TYPE(VSL_CONV_TASK) for vslsconvexecx1d, vsldconvexecx1d, vslcconvexecx1d, vslzconvexecx1d</p>	Pointer to the task descriptor.

Name	Type	Description
	TYPE (VSL_CORR_TASK) for vslscorrexecx1d, vsldcorrexecx1d, vslccorrexecx1d, vslzcorrexecx1d C: VSLConvTaskPtr for vslsConvExecX1D, vsldConvExecX1D, vslcConvExecX1D, vslzConvExecX1D VSLCorrTaskPtr for vslsCorrExecX1D, vsldCorrExecX1D, vslcCorrExecX1D, vslzCorrExecX1D	
<i>x</i> , <i>y</i>	FORTRAN 77: REAL*4 for vslsconvexecx1d and vslscorrexecx1d, REAL*8 for vsldconvexecx1d and vsldcorrexecx1d, COMPLEX*8 forvslcconvexecx1d and vslccorrexecx1d, COMPLEX*16 forvslzconvexecx1d and vslzcorrexecx1d Fortran 90: REAL (KIND=4) , DIMENSION (*) for vslsconvexecx1d and vslscorrexecx1d,	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	REAL (KIND=8) , DIMENSION (*) for vsldconvexecx1d and vsldcorrexecx1d, COMPLEX (KIND=4) , DIMENSION (*) for vs1cconvexecx1d and vs1ccorrexecx1d, COMPLEX (KIND=8) , DIMENSION (*) for vs1zconvexecx1d and vs1zcorrexecx1d C: const float[] for vs1sConvExecX1D and vs1sCorrExecX1D, const double[] for vs1dConvExecX1D and vs1dCorrExecX1D, const MKL_Complex8[] for vs1cConvExecX1D and vs1cCorrExecX1D, const MKL_Complex16[] for vs1zConvExecX1D and vs1zCorrExecX1D	
ystride, zstride	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
z	<p>FORTRAN 77: REAL*4 for vslsconvexecx1d and vslscorrexecx1d,</p> <p>REAL*8 for vsldconvexecx1d and vsldcorrexecx1d,</p> <p>COMPLEX*8 forvslcconvexecx1d and vslccorrexecx1d,</p> <p>COMPLEX*16 forvslzconvexecx1d and vslzcorrexecx1d</p> <p>Fortran 90: REAL (KIND=4) , DIMENSION (*) for vslsconvexecx1d and vslscorrexecx1d,</p> <p>REAL (KIND=8) , DIMENSION (*) for vsldconvexecx1d and vsldcorrexecx1d,</p> <p>COMPLEX (KIND=4) , DIMENSION (*) forvslcconvexecx1d and vslccorrexecx1d,</p> <p>COMPLEX (KIND=8) , DIMENSION (*) for vslzconvexecx1d and vslzcorrexecx1d</p>	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	C: const float[] for vslsConvExecX1D and vslsCorrExecX1D, const double[] for vsldConvExecX1D and vsldCorrExecX1D, const MKL_Complex8[] for vslcConvExecX1D and vslcCorrExecX1D, const MKL_Complex16[] for vslzConvExecX1D and vslzCorrExecX1D	
<i>status</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

Each of the `ExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTaskX1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

DeleteTask

Destroys the task object and frees the memory.

Syntax

Fortran:

```
errcode = vslconvdeletetask(task)
errcode = vslcorrdeletetask(task)
```

C:

```
errcode = vslConvDeleteTask(task);
errcode = vslCorrDeleteTask(task);
```

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslconvdeletetask INTEGER*4 task(2) for vslcorrdeletetask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvdeletetask TYPE(VSL_CORR_TASK) for vslcorrdeletetask C: VSLConvTaskPtr* for vslConvDeleteTask	Pointer to the task descriptor.

Name	Type	Description
	VSLCorrTaskPtr* for vslCorrDeleteTask	

Output Parameters

Name	Type	Description
<i>errcode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Contains 0 if the task object is deleted successfully. Contains error code if an error occurred.

Description

This routine is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

Given a pointer to a task descriptor, this routine deletes the task descriptor object and frees the memory allocated for the data structure. If the task holds a work memory, the latter is also freed. The task pointer is set to `NULL`.

Note that if by some reason the task was not deleted successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE. You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine will be terminated and no system crash will occur.

Task Copy

The routines are designed for copying convolution and correlation task descriptors.

CopyTask

Copies a descriptor for convolution or correlation task.

Syntax

Fortran:

```
status = vslconvcopytask(newtask, srctask)
status = vslcorrcopytask(newtask, srctask)
```

C:

```
status = vslConvCopyTask(newtask, srctask);
status = vslCorrCopyTask(newtask, srctask);
```

Input Parameters

Name	Type	Description
<i>srctask</i>	FORTRAN 77: INTEGER*4 srctask(2) for vslconvcopytask INTEGER*4 srctask(2) for vslcorrcopytask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvcopytask TYPE(VSL_CORR_TASK) for vslcorrcopytask C: const VSLConvTaskPtr for vslConvCopyTask const VSLCorrTaskPtr for vslCorrCopyTask	Pointer to the source task descriptor.

Output Parameters

Name	Type	Description
<i>newtask</i>	FORTRAN 77: INTEGER*4 srctask(2) for vslconvcopytask INTEGER*4 srctask(2) for vslcorrcopytask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvcopytask TYPE(VSL_CORR_TASK) for vslcorrcopytask C: VSLConvTaskPtr* for vslConvCopyTask VSLCorrTaskPtr* for vslCorrCopyTask	Pointer to the new task descriptor.
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the source task.

Description

This routine is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

If a task object *srctask* already exists, you can use an appropriate `CopyTask` routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see [Overview](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single threaded and multiple threaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL* library. The functions assume single threaded calculations and can be used with C or C++ compilers.

Example 10-5 Function `scond1` for Single Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task, VSL_CONV_MODE_DIRECT, nh, nx, ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h, inch, x, incx, y, incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Example 10-6 Function `sconf1` for Single Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    int init,
    float h[], int inclh,
    float x[], int inclx, int inc2x,
    float y[], int incly, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;

    /* assume that aux1!=0 and naux1 is big enough */
```

```

VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;
if (init != 0)
    /* initialization: */
    status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
        nh, nx, ny, h, inclh);
if (init == 0) {
    /* calculations: */
    int i;
    vslConvSetStart(*task, &iy0);
    for (i=0; i<m; i++) {
        float* xi = &x[inc2x * i];
        float* yi = &y[inc2y * i];
        /* task is implicitly committed at i==0 */
        status = vslsConvExecX1D(*task, xi, inclx, yi, incly);
    };
};
vslConvDeleteTask(task);
return status;
}

```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If `m>1`, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create `m` copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code for that can look like following:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    . . .
    vslConvSetStart(*task, &iy0);
    . . .
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    . . .
```

Then, *m* threads may be started to execute different copies of the task:

```
. . .
    float* xi = &x[inc2x * i];
    float* yi = &y[inc2y * i];
    ss[i]=vs1sConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
    . . .
```

And finally, after all threads have finished the calculations, overall status ought to be collected from all task objects. The following code assumes signaling the first error found, if any:

```
. . .
    for (i=0; i<m; i++) {
        status = ss[i];
        if (status != 0) /* 0 means "OK" */
            break;
    };
    return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. This is the reason why different threads must use different copies of the task.

Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbf{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbf{Z} = \{0, \pm 1, \pm 2, \dots\}$	The set of integer numbers.
$\mathbf{Z}^N = \mathbf{Z} \times \dots \times \mathbf{Z}$	The set of N-dimensional series of integer numbers.
$p = (p_1, \dots, p_N) \in \mathbf{Z}^N$	N-dimensional series of integers.
$u: \mathbf{Z}^N \rightarrow \mathbf{R}$	Function u with arguments from \mathbf{Z}^N and values from \mathbf{R} .
$u(p) = u(p_1, \dots, p_N)$	The value of the function u for the argument (p_1, \dots, p_N) .
$w = u * v$	Function w is the convolution of the functions u, v .
$w = u \bullet v$	Function w is the correlation of the functions u, v .

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1, \dots, N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1, \dots, N$
- series $r = \sup\{p, q\}$ is defines as $r^n = \max\{p^n, q^n\}$ for every $n=1, \dots, N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1, \dots, N$
- inequality $p \leq q$ means that $p^n \leq q^n$ for every $n=1, \dots, N$.

A function $u(p)$ is called a finite function if there exist series $p^{\min}, p^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$p^{\min} \leq p \leq p^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series $p^{\min}, p^{\max}, q^{\min}, q^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0 \text{ implies } p^{\min} \leq p \leq p^{\max}.$$

$v(q) \neq 0$ implies $Q^{\min} \leq q \leq Q^{\max}$.

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u * v$ is the convolution of u and v , then:

$w(r) \neq 0$ implies $R^{\min} \leq r \leq R^{\max}$,
where $R^{\min} = P^{\min} + Q^{\min}$ and $R^{\max} = P^{\max} + Q^{\max}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$w(r) = \sum u(t) \cdot v(r-t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $T^{\min} \leq t \leq T^{\max}$,
where $T^{\min} = \sup\{P^{\min}, r - Q^{\max}\}$ and $T^{\max} = \inf\{P^{\max}, r - Q^{\min}\}$.

Linear Correlation

If function $w = u \bullet v$ is the correlation of u and v , then:

$w(r) \neq 0$ implies $R^{\min} \leq r \leq R^{\max}$,
where $R^{\min} = Q^{\min} - P^{\max}$ and $R^{\max} = Q^{\max} - P^{\min}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$w(r) = \sum u(t) \cdot v(r+t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $T^{\min} \leq t \leq T^{\max}$,
where $T^{\min} = \sup\{P^{\min}, Q^{\min} - r\}$ and $T^{\max} = \inf\{P^{\max}, Q^{\max} - r\}$.

Representation of the functions u , v , w as the input/output data for the Intel MKL convolution and correlation functions is described in the [Data Allocation](#) section below.

Data Allocation

This section explains the relation between:

- mathematical finite functions u , v , w introduced in the section [Mathematical Notation and Definitions](#);
- multi-dimensional input and output data vectors representing the functions u , v , w ;
- arrays u , v , w used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays x, y, z
- Shape arrays $xshape, yshape, zshape$
- Strides within arrays $xstride, ystride, zstride$
- Parameters $start, decimation$

Finite Functions and Data Vectors

The finite functions $u(p)$, $v(q)$, and $w(r)$ introduced above are represented as multi-dimensional vectors of input and output data:

```
inputu(i1, ..., idims) for u(p1, ..., pN)
inputv(j1, ..., jdims) for v(q1, ..., qN)
output(k1, ..., kdims) for w(r1, ..., rN) .
```

Parameter $dims$ represents the number of dimensions and is equal to N .

The parameters $xshape, yshape$, and $zshape$ define the shapes of input/output vectors:

```
inputu(i1, ..., idims) is defined if  $1 \leq i_n \leq xshape(n)$  for every  $n=1, \dots, dims$ 
inputv(j1, ..., jdims) is defined if  $1 \leq j_n \leq yshape(n)$  for every  $n=1, \dots, dims$ 
output(k1, ..., kdims) is defined if  $1 \leq k_n \leq zshape(n)$  for every  $n=1, \dots, dims$ .
```

Relation between the input vectors and the functions u and v is defined by the following formulas:

```
inputu(i1, ..., idims) = u(p1, ..., pN), where  $p_n = P_n^{min} + (i_n - 1)$  for every  $n$ 
```

```
inputv(j1, ..., jdims) = v(q1, ..., qN), where  $q_n = Q_n^{min} + (j_n - 1)$  for every  $n$ .
```

Relation between the output vector and the function $w(r)$ is similar (but only in the case when parameters $start$ and $decimation$ are not defined):

```
output(k1, ..., kdims) = w(r1, ..., rN), where  $r_n = R_n^{min} + (k_n - 1)$  for every  $n$ .
```

If the parameter $start$ is defined, it must belong to the interval $R_n^{min} \leq start(n) \leq R_n^{max}$.

If defined, the $start$ parameter replaces R_n^{min} in the formula:

```
output(k1, ..., kdims) = w(r1, ..., rN), where  $r_n = start(n) + (k_n - 1)$ 
```

If the parameter *decimation* is defined, it changes the relation according to the following formula:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$, where $r_n = R_n^{\min} + (k_n - 1) \cdot \text{decimation}(n)$

If both parameters *start* and *decimation* are defined, the formula is as follows:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$, where $r_n = \text{start}(n) + (k_n - 1) \cdot \text{decimation}(n)$

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If r_n exceeds R_n^{\max} for some $k_n, n=1, \dots, \text{dims}$, an error is raised.

Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbf{Z}^N$, one-dimensional indices $e, f, g \in \mathbf{Z}$ are defined such that:

$\text{inputu}(i_1, \dots, i_{\text{dims}})$ is allocated at $x(e)$

$\text{inputv}(j_1, \dots, j_{\text{dims}})$ is allocated at $y(f)$

$\text{output}(k_1, \dots, k_{\text{dims}})$ is allocated at $z(g)$.

The indices *e*, *f*, and *g* are defined as follows:

$e = 1 + \sum \text{xstride}(n) \cdot dx(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$f = 1 + \sum \text{ystride}(n) \cdot dy(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$g = 1 + \sum \text{zstride}(n) \cdot dz(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

The distances $dx(n)$, $dy(n)$, and $dz(n)$ depend on the signum of the stride:

$dx(n) = i_n - 1$ if $\text{xstride}(n) > 0$, or $dx(n) = i_n - \text{xshape}(n)$ if $\text{xstride}(n) < 0$

$dy(n) = j_n - 1$ if $\text{ystride}(n) > 0$, or $dy(n) = j_n - \text{yshape}(n)$ if $\text{ystride}(n) < 0$

$dz(n) = k_n - 1$ if $\text{zstride}(n) > 0$, or $dz(n) = k_n - \text{zshape}(n)$ if $\text{zstride}(n) < 0$

The definitions of indices e , f , and g assume that indexes for arrays x , y , and z are started from unity:

$x(e)$ is defined for $e=1, \dots, \text{length}(x)$

$y(f)$ is defined for $f=1, \dots, \text{length}(y)$

$z(g)$ is defined for $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array z for one-dimensional and two-dimensional cases.

One-dimensional case. If $\text{dims}=1$, then zshape is the number of the output values to be stored in the array z . The actual length of array z may be greater than zshape elements.

If $\text{zstride}>1$, output values are stored with the stride: $\text{output}(1)$ is stored to $z(1)$, $\text{output}(2)$ is stored to $z(1+\text{zstride})$, and so on. Hence, the actual length of z must be at least $1+\text{zstride}*(\text{zshape}-1)$ elements or more.

If $\text{zstride}<0$, it still defines the stride between elements of array z . However, the order of the used elements is the opposite. For the k -th output value, $\text{output}(k)$ is stored in $z(1+|\text{zstride}|*(\text{zshape}-k))$, where $|\text{zstride}|$ is the absolute value of zstride . The actual length of the array z must be at least $1+|\text{zstride}|*(\text{zshape} - 1)$ elements.

Two-dimensional case. If $\text{dims}=2$, the output data is a two-dimensional matrix. The value $\text{zstride}(1)$ defines the stride inside matrix columns, that is, the stride between the $\text{output}(k_1, k_2)$ and $\text{output}(k_1+1, k_2)$ for every pair of indices k_1, k_2 . On the other hand, $\text{zstride}(2)$ defines the stride between columns, that is, the stride between $\text{output}(k_1, k_2)$ and $\text{output}(k_1, k_2+1)$.

If $\text{zstride}(2)$ is greater than $\text{zshape}(1)$, this causes sparse allocation of columns. If the value of $\text{zstride}(2)$ is smaller than $\text{zshape}(1)$, this may result in the transposition of the output matrix. For example, if $\text{zshape} = (2, 3)$, you can define $\text{zstride} = (3, 1)$ to allocate output values like transposed matrix of the shape 3×2 .

Whether zstride assumes this kind of transformations or not, you need to ensure that different elements $\text{output}(k_1, \dots, k_{\text{dims}})$ will be stored in different locations $z(g)$.

Fourier Transform Functions

This chapter describes the following implementations of the fast Fourier transform functions available in Intel® MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#) below)
- [Cluster FFT functions](#) for distributed-memory architectures (available with Intel® MKL for the Linux* and Windows* operating systems only).

The general form of the discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \dots, n_l-1$ ($l = 1, \dots, d$), where σ is an arbitrary real-valued scale factor, and the sign in the exponent is $\delta = -1$ for the forward transform and $\delta = +1$ for the backward transform. In most common situations, the domain of the forward transform, that is, the set where the input (periodic) sequence $\{w_{j_1, j_2, \dots, j_d}\}$ belongs, can be the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform, or backward domains, are represented by complex-valued sequences and complex-valued conjugate-even sequences.

Both groups of FFT functions above present a uniform and easy-to-use applications programmer interface providing fast computation of discrete Fourier transform via the fast Fourier transform algorithm.

The FFT functions support lengths with arbitrary factors. See the *Intel MKL User's Guide* for specific radices supported efficiently and the length constraints.

NOTE. The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide an efficient tool for conversion to and from the polar representation (see [Example C-30a in Appendix C](#) and [Example C-30b in Appendix C](#)).

FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional (up to rank 7) functions and both Fortran and C interfaces for all transform functions.

Table 11-1 lists FFT functions implemented in Intel MKL:

Table 11-1 FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
<code>DftiCreateDescriptor</code>	Allocates memory for the descriptor data structure and preliminarily initializes it.
<code>DftiCommitDescriptor</code>	Performs all initialization for the actual FFT computation.
<code>DftiCopyDescriptor</code>	Copies an existing descriptor.
<code>DftiFreeDescriptor</code>	Frees memory allocated for a descriptor.
FFT Computation Functions	
<code>DftiComputeForward</code>	Computes the forward FFT.
<code>DftiComputeBackward</code>	Computes the backward FFT.
Descriptor Configuration Functions	
<code>DftiSetValue</code>	Sets one particular configuration parameter with the specified configuration value.
<code>DftiGetValue</code>	Gets the value of one particular configuration parameter.
Status Checking Functions	
<code>DftiErrorClass</code>	Checks if the status reflects an error of a predefined class.
<code>DftiErrorMessage</code>	Generates an error message.

Description of the FFT functions is followed by discussion of configuration settings (see [Configuration Settings](#)) and various configuration parameters used.

Computing FFT

The FFT functions described later in this chapter are provided with the Fortran and C interfaces. Fortran stands for Fortran 95. The FFT interface relies critically on many modern features offered in Fortran 95 that have no counterpart in FORTRAN 77.

NOTE. Following the explicit function interface in Fortran, data array must be defined as one-dimensional for any transformation type.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

You can find code examples that use FFT interface functions to compute transform results in [Fourier Transform Functions Code Examples](#) section in the Appendix C.

For most common situations, an FFT computation can be effected by four function calls. The approach adopted in Intel MKL for FFT computation uses one single data structure, the descriptor, to record flexible configuration whose parameters can be changed independently. This results in enhanced functionality and ease of use.

The record of type `DFTI_DESCRIPTOR`, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of rather a large number of configuration parameters. The default settings for all of these parameters include, for example, the following:

- the FFT to be computed does not have a scale factor;
- there is only one set of data to be transformed;
- the data is stored contiguously in memory;
- the computed result overwrites (in place) the input data; etc.

Should any one of these many default settings be inappropriate, they can be changed one-at-a-time through the function `DftiSetValue` as illustrated in the [Example C-20](#) and [Example C-21](#).

FFT Interface

To use the FFT functions, you need to access the module `MKL_DFTI` through the "use" statement in Fortran; or access the header file `mkl_dfti.h` through "include" in C.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR`, a macro definition

```
#define DFTI_DESCRIPTOR_HANDLE DFTI_DESCRIPTOR *
```

a number of named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`; and a number of functions, some of which accept different number of input arguments.

NOTE. Some of the FFT functions and/or functionality described in the subsequent sections of this chapter may not be supported by the currently available implementation of the library. You can find the complete list of the implementation-specific exceptions in the release notes to your version of the library.

There are four main categories of FFT functions in Intel MKL:

1. Descriptor Manipulation. There are four functions in this category. The first one, `DftiCreateDescriptor`, creates an FFT descriptor whose storage is allocated dynamically. This function configures the descriptor with default settings corresponding to a few input values supplied by the user.

The second, `DftiCommitDescriptor`, "commits" the descriptor to all its setting. In practice, this usually means that all the necessary precomputation will be performed. This may include factorization of the input length and computation of all the required twiddle factors. The third function, `DftiCopyDescriptor`, makes an extra copy of a descriptor, and the fourth function, `DftiFreeDescriptor`, frees up all the memory allocated for the descriptor information.

2. FFT Computation. There are two functions in this category. The first, `DftiComputeForward`, performs the forward FFT computation, and the second function, `DftiComputeBackward`, performs a backward FFT computation.

3. Descriptor configuration. There are two functions in this category. One function, `DftiSetValue`, sets one specific value to one of the many configuration parameters that are changeable (a few are not); the other, `DftiGetValue`, gets the current value of any one of these configuration parameters (all are readable). These parameters, though many, are handled one-at-a-time.

4. Status Checking. The functions described in the three categories above return an integer value denoting the status of the operation. In particular, a non-zero return value always indicates a problem of some sort. Envisioned to be further enhanced in later releases of Intel MKL, FFT interface at present provides for one logical status class function, `DftiErrorClass`, and a simple status message generation function, `DftiErrorMessage`.

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. Two functions serve to check the status. The first function is a logical function that checks if the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

ErrorClass

Checks if the status reflects an error of a predefined class.

Syntax

Fortran:

```
Predicate = DftiErrorClass( Status, Error_Class )
```

C:

```
predicate = DftiErrorClass( status, error_class );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. The FFT interface in Intel MKL provides a set of predefined error classes listed in [Table 11-2](#). They are named constants and have the type `INTEGER` in Fortran and `MKL_LONG` in C.

Table 11-2 Predefined Error Classes

Named Constants	Comments
DFTI_NO_ERROR	No error. The zero status belongs to this class.
DFTI_MEMORY_ERROR	Usually associated with memory allocation
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters

Named Constants	Comments
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function)
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent
DFTI_MKL_INTERNAL_ERROR	Internal library error
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).

Function `DftiErrorClass` returns a nonzero value (the value of `.TRUE.` in Fortran) if the status belongs to a predefined error class. Note that direct comparison of a status with a predefined class is an incorrect usage. The correct way to check if a function call was successful is through the use of `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See [Example C-22](#) on a correct use of the status checking functions.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorClass
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
  FUNCTION some_actual_function_8( Status, Error_Class )
  LOGICAL some_actual_function_8
  INTEGER, INTENT(IN) :: Status, Error_Class
  END FUNCTION some_actual_function_8
END INTERFACE DftiErrorClass

/* C prototype */
MKL_LONG DftiErrorClass( MKL_LONG , MKL_LONG );
```

ErrorMessage

Generates an error message.

Syntax

Fortran:

```
ERROR_MESSAGE = DftiErrorMessage( Status )
```

C:

```
error_message = DftiErrorMessage( status );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. The error message function generates an error message character string. The maximum length of the string in Fortran is given by the named constant `DFTI_MAX_MESSAGE_LENGTH`. The actual error message is implementation dependent. In Fortran, the user needs to use a character string of length `DFTI_MAX_MESSAGE_LENGTH` as the target. In C, the function returns a pointer to a character string, that is, a character array with terminating `'\0'` character.

[Example C-22](#) shows how this function can be used.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorMessage
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
    FUNCTION some_actual_function_9( Status )
    CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) some_actual_function_9( Status )
    INTEGER, INTENT(IN) :: Status
    END FUNCTION some_actual_function_9
END INTERFACE DftiErrorMessage

/* C prototype */
char *DftiErrorMessage( MKL_LONG );
```

Descriptor Manipulation Functions

There are four functions in this category: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

CreateDescriptor

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptor( Desc_Handle, Precision, Forward_Domain, &
                               Dimension, Length )
```

C:

```
status = DftiCreateDescriptor( &desc_handle, precision, forward_domain,
                               dimension, length );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. Since memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function in more traditional software packages or libraries used for computing FFT. This function does not perform any significant computational work such as twiddle factors computation. The function [DftiCommitDescriptor](#) does this work after the function [DftiSetValue](#) has set values of all needed parameters.

The precision and (forward) domain are specified through named constants provided in the FFT interface for the configuration values. The choices for precision are `DFTI_SINGLE` and `DFTI_DOUBLE`; and the choices for (forward) domain are `DFTI_COMPLEX` and `DFTI_REAL`. See [Table 11-5](#) for the complete table of named constants for configuration values.

Dimension is a simple positive integer indicating the dimension of the transform. Length is either a simple positive integer for one-dimensional transform, or an integer array (pointer in C) containing the positive integers corresponding to the length dimensions for multi-dimensional transform.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.

INTERFACE DftiCreateDescriptor

    FUNCTION some_actual_function_1d(desc, precision, domain, dim, length)
        INTEGER :: some_actual_function_1d
        ...
        INTEGER, INTENT(IN) :: length
    END FUNCTION some_actual_function_1d

    FUNCTION some_actual_function_md(desc, precision, domain, dim, lengths)
        INTEGER :: some_actual_function_md
        ...
        INTEGER, INTENT(IN), DIMENSION(*) :: lengths
    END FUNCTION some_actual_function_md

    ...

END INTERFACE DftiCreateDescriptor
```

Note that the function is overloaded, because the actual parameter for the formal parameter *length* can be a scalar or a rank-one array.

The function is also overloaded with respect to the type of the *precision* parameter to provide an option of using a precision-specific function for the generic name. Using more specific functions can reduce the size of statically linked executable for the applications using only single-precision FFTs or only double-precision FFTs. To use this option, change statement "USE MKL_DFTI" in your program unit to either of the following:

```
USE MKL_DFTI, FORGET=>DFTI_SINGLE, DFTI_SINGLE=>DFTI_SINGLE_R
USE MKL_DFTI, FORGET=>DFTI_DOUBLE, DFTI_DOUBLE=>DFTI_DOUBLE_R
```

where the name "FORGET" can be replaced with any name that is not used in the program unit.

```
/* C prototype.
 * Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
 */
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
    enum DFTI_CONFIG_VALUE precision,
    enum DFTI_CONFIG_VALUE domain,
    MKL_LONG dimension, ... /* length(s) */ );

#define DftiCreateDescriptor(desc,prec,domain,dim,sizes) \
    ((prec)==DFTI_SINGLE && (dim)==1) ? \
    some_actual_function_sld((desc),(domain),(MKL_LONG)(sizes)) : \
    ...
```

Variable *length(s)* is interpreted as a scalar (MKL_LONG) or an array (MKL_LONG*), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, then the compiler may retain, at a certain level of optimization, only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel MKL FFT header file, as follows:

```
#include "mkl_dfti.h"
#undef DftiCreateDescriptor
```

CommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptor( Desc_Handle )
```

C:

```
status = DftiCommitDescriptor( desc_handle );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. The interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations. Typically, this committal performs all initialization that facilitates the actual FFT computation. For a modern implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function call is immediately followed by a computation function call (see [FFT Computation](#)).

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCommitDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
    FUNCTION some_actual function_1 ( Desc_Handle )
    INTEGER :: some_actual function_1
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
    END FUNCTION some_actual function_1
END INTERFACE DftiCommitDescriptor
```

```
/* C prototype */  
MKL_LONG DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );
```

CopyDescriptor

Copies an existing descriptor.

Syntax

Fortran:

```
Status = DftiCopyDescriptor( Desc_Handle_Original, Desc_Handle_Copy )
```

C:

```
status = DftiCopyDescriptor( desc_handle_original, &desc_handle_copy );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function makes a copy of an existing descriptor and provides a pointer to it. The purpose is that all information of the original descriptor will be maintained even if the original is destroyed via the free descriptor function

`DftiFreeDescriptor`.

The function returns the zero status when completes successfully. The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCopyDescriptor
! Note that the body provided here is to illustrate the different
! argument list and types of dummy arguments. The interface
! does not guarantee what the actual function names are.
! Users can only rely on the function name following the
! keyword INTERFACE
    FUNCTION some_actual_function_2( Desc_Handle_Original,
    Desc_Handle_Copy )
    INTEGER :: some_actual_function_2
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Original, Desc_Handle_Copy
    END FUNCTION some_actual_function_2
END INTERFACE DftiCopyDescriptor

/* C prototype */
MKL_LONG DftiCopyDescriptor( DFTI_DESCRIPTOR_HANDLE, DFTI_DESCRIPTOR_HANDLE * );
```

FreeDescriptor

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptor( Desc_Handle )
```

C:

```
status = DftiFreeDescriptor( &desc_handle );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function frees up all memory space allocated for a descriptor.

NOTE. Memory allocation/deallocation inside Intel MKL is managed by Intel MKL Memory Manager. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the Memory Manager sometimes does not return the memory space to the OS but considers the space free and can reuse it for future memory allocation. See [Example “MKL_FreeBuffers Usage with FFT Functions”](#) in the description of the service function `FreeBuffers` on how to use Intel MKL Memory Manager and actually release memory.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiFreeDescriptor
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
    FUNCTION some_actual_function_3( Desc_Handle )
        INTEGER :: some_actual_function_3
        TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
    END FUNCTION some_actual_function_3
END INTERFACE DftiFreeDescriptor
```

```
/* C prototype */
MKL_LONG DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

FFT Computation Functions

There are two functions in this category: compute the forward transform, and compute the backward transform.

ComputeForward

Computes the forward FFT.

Syntax

Fortran:

```
status = DftiComputeForward( desc_handle, x_inout )
status = DftiComputeForward( desc_handle, x_in, y_out )
status = DftiComputeForward ( desc_handle, xre_inout, xim_inout )
status = DftiComputeForward ( desc_handle, xre_in, xim_in , yre_out,
yim_out )
```

C:

```
status = DftiComputeForward( desc_handle, x_inout );
status = DftiComputeForward( desc_handle, x_in, y_out );
status = DftiComputeForward ( desc_handle, xre_inout, xim_inout );
status = DftiComputeForward ( desc_handle, xre_in, xim_in , yre_out,
yim_out );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and in the `mkl_dfti.f90` module file for the Fortran interface. The function accepts the descriptor handle parameter and one or more data parameters. Provided the descriptor is configured and

committed successfully, actual computation of the FFT can be performed. Function `DftiComputeForward` computes the forward FFT, that is, the transform with the minus sign in the exponent, $\delta = -1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by the variable parameters in C and the generic interface in Fortran. The Fortran implementation can check for inconsistency between the required and actual number of parameters.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeForward

    FUNCTION some_actual_function_1(desc,sSrcDst)
        INTEGER some_actual_function_1
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
        ...
    END FUNCTION some_actual_function_1

    FUNCTION some_actual_function_2(desc,cSrcDst)
        INTEGER some_actual_function_2
        COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
        ...
    END FUNCTION some_actual_function_2

    FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
        INTEGER some_actual_function_3
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
        ...
    END FUNCTION some_actual_function_3
    ...
END INTERFACE DftiComputeForward
```

Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular "stride" pattern capable to describe

multidimensional array layout (discussed more fully in [Strides](#), see also [3]), and the function requires the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

```
/* C prototype */
MKL_LONG DftiComputeForward( DFTI_DESCRIPTOR_HANDLE, void*, ... );
```

ComputeBackward

Computes the backward FFT.

Syntax

Fortran:

```
status = DftiComputeBackward( desc_handle, x_inout )
status = DftiComputeBackward( desc_handle, y_in, x_out )
status = DftiComputeBackward ( desc_handle, xre_inout, xim_inout )
status = DftiComputeBackward ( desc_handle, yre_in, yim_in , xre_out,
xim_out )
```

C:

```
status = DftiComputeBackward( desc_handle, x_inout );
status = DftiComputeBackward( desc_handle, y_in, x_out );
status = DftiComputeBackward ( desc_handle, xre_inout, xim_inout );
status = DftiComputeBackward ( desc_handle, yre_in, yim_in , xre_out,
xim_out );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` module file for the Fortran interface. The function accepts the descriptor handle parameter and one or more data parameters. Provided the descriptor is configured and committed successfully, actual computation of the FFT can be performed. Function `DftiComputeBackward` computes the inverse FFT, that is, the transform with the plus sign in the exponent, $\delta = +1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by the variable parameters in C and the generic interface in Fortran. The Fortran implementation can check for inconsistency between the required and actual number of parameters.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeBackward

    FUNCTION some_actual_function_1(desc,sSrcDst)
        INTEGER some_actual_function_1
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
        ...
    END FUNCTION some_actual_function_1

    FUNCTION some_actual_function_2(desc,cSrcDst)
        INTEGER some_actual_function_2
        COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
        ...
    END FUNCTION some_actual_function_2

    FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
        INTEGER some_actual_function_3
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
        ...
    END FUNCTION some_actual_function_3

    ...
END INTERFACE DftiComputeBackward
```

Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular "stride" pattern capable to describe multidimensional array layout (discussed more fully in [Strides](#), see also [3]), and the function

requires the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

```
/* C prototype */
MKL_LONG DftiComputeBackward( DFTI_DESCRIPTOR_HANDLE, void *, ... );
```

Descriptor Configuration Functions

There are two functions in this category: the value setting function `DftiSetValue` sets one particular configuration parameter to an appropriate value, and the value getting function `DftiGetValue` reads the value of one particular configuration parameter. While all configuration parameters are readable, a few of them cannot be set by user. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, but nevertheless are derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

SetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValue( Desc_Handle, Config_Param, Config_Val )
```

C:

```
status = DftiSetValue( desc_handle, config_param, config_val );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in [Table 11-3](#), and the configuration value must have the corresponding type, which can be a named constant or a native type. See [Configuration Settings](#) for details of the meaning of

the setting. Note that you can set configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS` only through the [DftiCreateDescriptor](#) function. The `DftiSetValue` function does not change these parameters.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiSetValue
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
    FUNCTION some_actual_function_6_INTVAL( Desc_Handle, Config_Param, INTVAL )
        INTEGER :: some_actual_function_6_INTVAL
        Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
        INTEGER, INTENT(IN) :: Config_Param
        INTEGER, INTENT(IN) :: INTVAL
    END FUNCTION some_actual_function_6_INTVAL

    FUNCTION some_actual_function_6_SGLVAL( Desc_Handle, Config_Param, SGLVAL )
        INTEGER :: some_actual_function_6_SGLVAL
        Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
        INTEGER, INTENT(IN) :: Config_Param

```

GetValue

Gets the configuration value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValue( Desc_Handle, Config_Param, Config_Val )
```

C:

```
status = DftiGetValue( desc_handle, config_param, &config_val );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in [Table 11-3](#) and [Table 11-4](#), and the configuration value is the corresponding appropriate type, which can be a named constant or a native type.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiGetValue

Configuration Settings

Each of the configuration parameters is identified by a named constant in the MKL_DFTI module. In C, these named constants have the enumeration type DFTI_CONFIG_PARAM. The list of configuration parameters whose values can be set by user is given in Table 11-3; the list of configuration parameters that are read-only is given in Table 11-4. All parameters are readable. Most of these parameters are self-explanatory, while some others are discussed more fully in the description of the relevant functions.

Table 11-3 Settable Configuration Parameters

Named Constants	Value Type	Comments
<i>Most common configurations, no default, must be set explicitly</i>		
DFTI_FORWARD_DOMAIN	Named constant	Domain for the forward transform, settable by DftiCreateDescriptor only
DFTI_PRECISION	Named constant	Precision of computation, settable by DftiCreateDescriptor only
DFTI_DIMENSION	Integer scalar	Dimension of the transform, settable by DftiCreateDescriptor only
DFTI_LENGTHS	Integer scalar/array	Lengths of each dimension, settable by DftiCreateDescriptor only
<i>Common configurations including multiple transform and data representation</i>		
DFTI_NUMBER_OF_TRANSFORMS	Integer scalar	For multiple number of transforms
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor for forward transform
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor for backward transform
DFTI_PLACEMENT	Named constant	Placement of the computation result

Named Constants	Value Type	Comments
DFTI_COMPLEX_STORAGE	Named constant	Storage method, complex domain data
DFTI_REAL_STORAGE	Named constant	Storage method, real domain data
DFTI_CONJUGATE_EVEN_STORAGE	Named constant	Storage method, conjugate-even domain data
DFTI_DESCRIPTOR_NAME	Character string	No longer than DFTI_MAX_NAME_LENGTH
DFTI_PACKED_FORMAT	Named constant	Packed format, real domain data
DFTI_NUMBER_OF_USER_THREADS	Integer scalar	Number of user threads employing the same descriptor for FFT computation
<i>Configurations regarding stride of data</i>		
DFTI_INPUT_DISTANCE	Integer scalar	Multiple transforms, distance of first elements
DFTI_OUTPUT_DISTANCE	Integer scalar	Multiple transforms, distance of first elements
DFTI_INPUT_STRIDES	Integer array	Stride information of input data
DFTI_OUTPUT_STRIDES	Integer array	Stride information of output data
<i>Advanced configuration</i>		
DFTI_ORDERING	Named constant	Scrambling of data order
DFTI_TRANSPOSE	Named constant	Scrambling of dimension

Table 11-4 Read-Only Configuration Parameters

Named Constants	Value Type	Comments
DFTI_COMMIT_STATUS	Name constant	Whether descriptor has been committed
DFTI_VERSION	String	Intel MKL library version number

The configuration parameters are set by various values. Some of these values are specified by native data types such as an integer value (for example, number of simultaneous transforms requested), or a single-precision number (for example, the scale factor one would like to apply on a forward transform).

Other configuration values are discrete in nature (for example, the domain of the forward transform) and are thus provided in the DFTI module as named constants. In C, these named constants have the enumeration type `DFTI_CONFIG_VALUE`. The complete list of named constants used for this kind of configuration values is given in [Table 11-5](#).

Table 11-5 Named Constant Configuration Values

Named Constant	Comments
DFTI_SINGLE	Single precision
DFTI_DOUBLE	Double precision
DFTI_COMPLEX	Complex domain
DFTI_REAL	Real domain
DFTI_INPLACE	Output overwrites input
DFTI_NOT_INPLACE	Output does not overwrite input
DFTI_COMPLEX_COMPLEX	Storage method (see Storage schemes)
DFTI_REAL_REAL	Storage method (see Storage schemes)
DFTI_COMPLEX_REAL	Storage method (see Storage schemes)
DFTI_REAL_COMPLEX	Storage method (see Storage schemes)
DFTI_COMMITTED	Committal status of a descriptor
DFTI_UNCOMMITTED	Committal status of a descriptor
DFTI_ORDERED	Data ordered in both forward and backward domains

Named Constant	Comments
DFTI_BACKWARD_SCRAMBLED	Data scrambled in backward domain (by forward transform)
DFTI_NONE	Used to specify no transposition
DFTI_CCS_FORMAT	Packed format, real data (see Packed formats)
DFTI_PACKED_FORMAT	Packed format, real data (see Packed formats)
DFTI_PERM_FORMAT	Packed format, real data (see Packed formats)
DFTI_CCE_FORMAT	Packed format, real data (see Packed formats)
DFTI_VERSION_LENGTH	Number of characters for library version length
DFTI_MAX_NAME_LENGTH	Maximum descriptor name length
DFTI_MAX_MESSAGE_LENGTH	Maximum status message length

Table 11-6 lists the possible values for those configuration parameters that are discrete in nature.

Table 11-6 Settings for Discrete Configuration Parameters

Named Constant	Possible Values
DFTI_PRECISION	DFTI_SINGLE, or DFTI_DOUBLE (no default)
DFTI_FORWARD_DOMAIN	DFTI_COMPLEX, or DFTI_REAL
DFTI_PLACEMENT	DFTI_INPLACE (default), or DFTI_NOT_INPLACE
DFTI_COMPLEX_STORAGE	DFTI_COMPLEX_COMPLEX (default)
DFTI_REAL_STORAGE	DFTI_REAL_REAL (default), or DFTI_REAL_COMPLEX
DFTI_CONJUGATE_EVEN_STORAGE	DFTI_COMPLEX_COMPLEX, or DFTI_COMPLEX_REAL (default)

Named Constant	Possible Values
DFTI_PACKED_FORMAT	DFTI_CCS_FORMAT (default), or DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT, or DFTI_CCE_FORMAT
DFTI_ORDERING	DFTI_ORDERED (default), or DFTI_BACKWARD_SCRAMBLED

[Table 11-7](#) lists the default values of the settable configuration parameters.

Table 11-7 Default Configuration Values of Settable Parameters

Named Constants	Default Value
DFTI_NUMBER_OF_TRANSFORMS	1
DFTI_NUMBER_OF_USER_THREADS	1
DFTI_FORWARD_SCALE	1.0
DFTI_BACKWARD_SCALE	1.0
DFTI_PLACEMENT	DFTI_INPLACE
DFTI_COMPLEX_STORAGE	DFTI_COMPLEX_COMPLEX
DFTI_REAL_STORAGE	DFTI_REAL_REAL
DFTI_CONJUGATE_EVEN_STORAGE	DFTI_COMPLEX_REAL
DFTI_PACKED_FORMAT	DFTI_CCS_FORMAT
DFTI_DESCRIPTOR_NAME	no name, string of zero length
DFTI_INPUT_DISTANCE	0
DFTI_OUTPUT_DISTANCE	0
DFTI_INPUT_STRIDES	Tightly packed according to dimension and FFT lengths
DFTI_OUTPUT_STRIDES	Same as above. see Strides for details

Named Constants	Default Value
DFTI_ORDERING	DFTI_ORDERED
DFTI_TRANSPOSE	DFTI_NONE

Precision of transform

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data is meant to be presented in this precision; the computation will be carried out in this precision; and the result will be delivered in this precision. This is one of the four settable configuration parameters that do not have default values. The user must set them explicitly, most conveniently at the call to descriptor creation function [DftiCreateDescriptor](#).

Fortran module `MKL_DFTI` also defines named constants `DFTI_SINGLE_R` and `DFTI_DOUBLE_R`, with the same semantics as `DFTI_SINGLE` and `DFTI_DOUBLE`, respectively. These constants are *not recommended for direct use*. They only facilitate access to precision-specific functions for the generic name `DftiCreateDescriptor` through the modification of the "USE MKL_DFTI" statement, as described in section [CreateDescriptor](#).

Forward domain of transform

As already mentioned in the introduction to the Fourier Transform Functions chapter, the general form of the discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

where w is the input sequence, z is the output sequence, both indexed by $k_l = 0, \dots, n_l-1$, for $l = 1, \dots, d$, scale factor σ is an arbitrary real number with the default value of 1.0, and the sign in the exponent is $\delta = -1$ for the forward transform and $\delta = +1$ for the backward transform.

The implementation of FFT supports forward transforms on input sequences of two domains, as specified by configuration parameter `DFTI_FORWARD_DOMAIN`: general complex-valued sequences (`DFTI_COMPLEX` domain) and general real-valued sequences (`DFTI_REAL` domain).

The forward transform maps the forward domain to the corresponding backward domain, as shown in [Table 11-8](#), where the conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x_{k_1, k_2, \dots, k_d} = \overline{x_{n_1 - k_1, n_2 - k_2, \dots, n_d - k_d}}$$

Here the overline denotes the complex conjugate, and it is assumed that

$$x_{\dots, n_l, \dots} \equiv x_{\dots, 0, \dots}$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in [Storage schemes](#).

Table 11-8 Correspondence of Forward and Backward Domain

Forward Domain	Implied Backward Domain
Complex (DFTI_COMPLEX)	Complex (DFTI_COMPLEX)
Real (DFTI_REAL)	Conjugate-even

DFTI_FORWARD_DOMAIN is the second of four configuration parameters without a default value.

Transform dimension and lengths

The dimension of the transform is a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For multi-dimensional (≥ 2) transform, the lengths of each of the dimension is supplied in an integer array (`Integer` data type in Fortran and `MKL_LONG` data type in C). `DFTI_DIMENSION` and `DFTI_LENGTHS` are the remaining two of four configuration parameters without default.

As mentioned, these four configuration parameters do not have default value. They are most conveniently set at the descriptor creation function. They can only be set in the descriptor creation function, and not by the function `DftiSetValue`.

Number of transforms

In some situations, the user may need to perform a number of FFTs of the same dimension and lengths. The most common situation would be to transform a number of one-dimensional data of the same length. This parameter has the default value of 1, and can be set to positive

integer value by an `Integer` data type in Fortran and `MKL_LONG` data type in C. Data sets have no common elements. The distance parameter is obligatory if multiple number is more than one.

Scale

The forward transform and backward transform are each associated with a scale factor σ of its own with default value of 1. The user can set one or both of them via the two configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length n , one can use the default scale of 1 for the forward transform while setting the scale factor for backward transform to be $1/n$, making the backward transform the inverse of the forward transform.

The scale factor configuration parameter should be set by a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

Placement of result

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. The user can change that by setting it to `DFTI_NOT_INPLACE`. Data sets have no common elements.

Storage schemes

Depending on the value of configuration parameter `DFTI_FORWARD_DOMAIN`, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined by a generalized stride (see [Strides](#)). For multiple transforms an n th set of data (n th begins with zero) should be located within the same memory block, and the data sets are placed at a distance from each other (see [Number of transforms](#) and [Input and output distances](#)).

NOTE. In C/C++, avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

Below the C/C++ notation is used to precisely describe association of mathematical entities with the data elements stored in memory. [FFT Examples](#) demonstrate the usage of storage formats in C and Fortran.

Storage schemes for complex domain. For the `DFTI_COMPLEX` forward domain, both input and output sequences belong to the complex domain. In this case, configuration parameter `DFTI_COMPLEX_STORAGE` can have one of the two values: `DFTI_COMPLEX_COMPLEX` (default) or `DFTI_REAL_REAL`.

NOTE. In the Intel MKL FFT implementation, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With `DFTI_COMPLEX_COMPLEX` storage, the complex-valued data sequence is referenced by a single data parameter `z` associated with the complex type so that complex-valued element

$$z_{k_1, k_2, \dots, k_d}$$

of the sequence is located at `z[nth*distance + stride0 + k1*stride1 + k2*stride2 + ... kd*strided]` as a structure consisting of the real and imaginary parts.

The following example illustrates a typical usage of the `DFTI_COMPLEX_COMPLEX` storage:

```
complex :: x(n)
...
! on input, for i=1,...,N: x(i) = wi-1
status = DftiComputeForward( desc_handle, x )
! on output, for i=1,...,N: x(i) = zi-1
```

With the `DFTI_REAL_REAL` storage, the complex-valued data sequence is referenced by two data parameters `ZRe` and `ZIm`, both associated with the real type so that complex-valued element

$$z_{k_1, k_2, \dots, k_d}$$

of the sequence is computed as `ZRe[nth*distance + stride0 + k1*stride1 + k2*stride2 + ... kd*strided] + $\sqrt{-1}$ × ZIm[nth*distance + stride0 + k1*stride1 + k2*stride2 + ... kd*strided].`

A typical usage of the `DFTI_REAL_REAL` storage is illustrated by the following example:

```
real :: xre(n), xim(n)
...
status = DftiSetValue( desc_handle, DFTI_COMPLEX_STORAGE, DFTI_REAL_REAL)
! on input, for i=1,...,N: cmplx(xre(i),xim(i)) = wi-1
status = DftiComputeForward( desc_handle, xre, xim )
! on output, for i=1,...,N: cmplx(xre(i),xim(i)) = zi-1
```

Storage scheme for the real and conjugate-even domains. This setting for the storage schemes for these domains is recorded in the configuration parameters `DFTI_REAL_STORAGE` and `DFTI_CONJUGATE_EVEN_STORAGE`. Since a forward real domain corresponds to a conjugate-even backward domain, they are considered together. The example uses [one-](#), [two-](#) and [three-dimensional](#) real to conjugate-even transforms. In-place computation is assumed whenever possible (that is, when the input data type matches the output data type).

One-Dimensional Transform

Consider a one-dimensional *n*-length transform of the form

$$z_k = \sum_{j=0}^{n-1} w_j e^{-i2\pi jk/n}, \quad w_j \in R, z_k \in C.$$

There is a symmetry:

For even *n*: $z(n/2+i) = \text{conjg}(z(n/2-i))$, $1 \leq i \leq n/2-1$, and moreover $z(0)$ and $z(n/2)$ are real values.

For odd *n*: $z(m+i) = \text{conjg}(z(m-i+1))$, $1 \leq i \leq m$, and moreover $z(0)$ is real value.

$m = \text{floor}(n/2)$.

					Im(z3)		

Assume that the stride has the default value (unit stride).

This complex conjugate-symmetric vector can be stored in the complex array of size m+1 or in the real array of size 2m+2 or 2m depending on packed format.

Two-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a two-dimensional real matrix according to the mathematical equation

$$Z_{i,j} = \sum_{k=0}^{m-1} \sum_{l=0}^{n-1} t_{k,l} * W_m^{-i*k} * W_n^{-j*l},$$

$$0 \leq i \leq m-1, 0 \leq j \leq n-1$$

$t_{k,l} = \text{cmplx}(r_{k,l}, 0)$, where $r_{k,l}$ is a real input matrix, $0 \leq k \leq m-1$, $0 \leq l \leq n-1$. The mathematical result $z_{i,j}$, $0 \leq i \leq m-1$, $0 \leq j \leq n-1$, is the complex matrix of size (m, n) . Each column is the complex conjugate-symmetric vector as follows:

For even m :

for $0 \leq j \leq n-1$,

$z(m/2+i, j) = \text{conjg}(z(m/2-i, j)), 1 \leq i \leq m/2-1$.

Moreover, $z(0, j)$ and $z(m/2, j)$ are real values for $j=0$ and $j=n/2$.

For odd m :

for $0 \leq j \leq n-1$,

$z(s+i, j) = \text{conjg}(z(s-i, j)), 1 \leq i \leq s-1$,

where $s = \text{floor}(m/2)$.

Moreover, $z(0, j)$ are real values for $j=0$ and $j=n/2$.

This mathematical result can be stored in the real two-dimensional array of size:

$(m+2, n+2)$ (CCS format), or
 (m, n) (Pack or Perm formats), or
 $(2*(m/1+1), n)$ (CCE format, Fortran-interface),
 $((m, 2*(n/2+1)))$ (CCE format, C-interface)

or in the complex two-dimensional array of size:

($m/2+1$, n) (CCE format, Fortran-interface),

(m , $n/2+1$) (CCE format, C-interface)

Since the multidimensional array data are arranged differently in Fortran and C (see [Strides](#)), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

The following tables give examples of output data layout in `Pack` format for a forward two-dimensional real-to-complex FFT of a 6-by-4 real matrix. Note that the same layout is used for the input data of the corresponding backward complex-to-real FFT.

Table 11-15 Fortran-interface Data Layout for a 6-by-4 Matrix

$z(1,1)$	$\text{Re } z(1,2)$	$\text{Im } z(1,2)$	$z(1,3)$

$\text{Im } z(2,1)$	$\text{Im } z(2,2)$	$\text{Im } z(2,3)$	$\text{Im } z(2,4)$
$\text{Re } z(3,1)$	$\text{Re } z(3,2)$	$\text{Re } z(3,3)$	$\text{Re } z(3,4)$
$\text{Im } z(3,1)$	$\text{Im } z(3,2)$	$\text{Im } z(3,3)$	$\text{Im } z(3,4)$
$z(4,1)$	$\text{Re } z(4,2)$	$\text{Im } z(4,2)$	$z(4,3)$

For the above example, the stride array is taken to be (0, 1, 6).

Table 11-16 C-interface Data Layout for a 6-by-4 Matrix

$z(1,1)$	$\text{Re } z(1,2)$	$\text{Im } z(1,2)$	$z(1,3)$
$\text{Re } z(2,1)$	$\text{Re } z(2,2)$	$\text{Im } z(2,2)$	$\text{Re } z(2,3)$
$\text{Im } z(2,1)$	$\text{Re } z(3,2)$	$\text{Im } z(3,2)$	$\text{Im } z(2,3)$
$\text{Re } z(3,1)$	$\text{Re } z(4,2)$	$\text{Im } z(4,2)$	$\text{Re } z(3,3)$
$\text{Im } z(3,1)$	$\text{Re } z(5,2)$	$\text{Im } z(5,2)$	$\text{Im } z(3,3)$
$z(4,1)$	$\text{Re } z(6,2)$	$\text{Im } z(6,2)$	$z(4,3)$

For the second example, the stride array is taken to be (0, 4, 1).

See also [Packed formats](#).

Three-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a three-dimensional real matrix according to the mathematical equation

$$Z_{i,j,q} = \sum_{k=0}^{m-1} \sum_{l=0}^{n-1} \sum_{s=0}^{k-1} t_{p,l,s} * W_m^{-i*p} * W_n^{-j*l} * W_k^{-q*s},$$

$$0 \leq i \leq m-1, 0 \leq j \leq n-1, 0 \leq s \leq k-1$$

$t_{p,l,s} = \text{cmplx}(r_{p,l,s}, 0)$, where $r_{p,l,s}$ is a real input matrix, $0 \leq k \leq m-1$, $0 \leq l \leq n-1$, $0 \leq s \leq k-1$. The mathematical result $z_{i,j,q}$, $0 \leq i \leq m-1$, $0 \leq j \leq n-1$, $0 \leq q \leq k-1$ is the complex matrix of size (m, n, k) , which is a complex conjugate-symmetric, or conjugate-even, matrix as follows:

$z_{m1,n1,k1} = \text{conjg}(z_{m-m1,n-n1,k-k1})$, where each dimension is periodic.

This mathematical result can be stored in the real three-dimensional array of size:

$(m/2+1, n, k)$ (CCE format, Fortran-interface),

$(m, n, k/2+1)$ (CCE format, C-interface).

Since the multidimensional array data are arranged differently in Fortran and C (see [Strides](#)), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

NOTE. There is one packed format for 3D REAL FFT - CCE format. In both in-place and out-of-place REAL FFT, for real data, the stride and distance parameters are in `REAL` units and for complex data, they are in `COMPLEX` units. So, elements of input and output data can be placed in different elements of input-output array of the in-place FFT.

1. `DFTI_REAL_REAL` for real domain, `DFTI_COMPLEX_REAL` for conjugate-even domain (by default). It is used for 1D and 2D REAL FFT.

- A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:2*m+1)
...some other code...
...assuming inplace transform...
Status = DftiComputeForward( Desc_Handle, X )
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

Output data stored in one of formats: `Pack`, `Perm` or `CCS` (see [Packed formats](#)).

CCS format: $X(2*k) = \text{Re}(z_k), X(2*k+1) = \text{Im}(z_k), k = 0, 1, \dots, m.$

Pack format:

even n: $X(0) = \text{Re}(z_0), X(2*k-1) = \text{Re}(z_k), X(2*k) = \text{Im}(z_k), k = 1, \dots, m-1,$
and $X(n-1) = \text{Re}(z_m)$

odd n: $X(0) = \text{Re}(z_0), X(2*k-1) = \text{Re}(z_k), X(2*k) = \text{Im}(z_k), k = 1, \dots, m$

Perm format:

even n: $X(0) = \text{Re}(z_0), X(1) = \text{Re}(z_m), X(2*k) = \text{Re}(z_k), X(2*k+1) = \text{Im}(z_k),$
 $k = 1, \dots, m-1,$

odd n: $X(0) = \text{Re}(z_0), X(2*k-1) = \text{Re}(z_k), X(2*k) = \text{Im}(z_k), k = 1, \dots, m.$

See [Example C-16](#), [Example C-17](#), [Example C-18](#), and [Example C-19](#).

Input and output data exchange the roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:n-1)
REAL :: Y(0:2*m+1)
...some other code...
...assuming out-of-place transform...
Status = DftiComputeForward( Desc_Handle, X, Y )
```

On input, $X(j) = w_j$, $j = 0, 1, \dots, n-1$.

On output,

Output data stored in one of formats: `Pack`, `Perm` or `CCS` (see [Packed formats](#)).

CCS format: $Y(2*k) = \text{Re}(z_k)$, $Y(2*k+1) = \text{Im}(z_k)$, $k = 0, 1, \dots, m$.

Pack format:

even n : $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m-1$,
and $Y(n-1) = \text{Re}(z_m)$

odd n : $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$

Perm format:

even n : $Y(0) = \text{Re}(z_0)$, $Y(1) = \text{Re}(z_m)$, $Y(2*k) = \text{Re}(z_k)$, $Y(2*k+1) = \text{Im}(z_k)$,
 $k = 1, \dots, m-1$,

odd n : $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$.

Notice that if the stride of the output array is not set to the default value unit stride, the real and imaginary parts of one complex element will be placed with this stride.

For example:

CCS format: $Y(2*k*s) = \text{Re}(z_k)$, $Y((2*k+1)*s) = \text{Im}(z_k)$, $k = 0, 1, \dots, m$, s - stride.

See [Example C-16a](#) and [Example C-17a](#).

Input and output data exchange the roles in the backward transform.

2. **DFTI_REAL_REAL** for real domain, **DFTI_COMPLEX_COMPLEX** for conjugate-even domain. It is used for 1D, 2D and 3D REAL FFT. The CCE format is set by default. You must explicitly set the storage scheme in this case, because its value is not the default one.

- A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:m*2)
...some other code...
...assuming in-place transform...
Status = DftiSetValue( Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
...
Status = DftiComputeForward( Desc_Handle, X)
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

$X(2*k) = \text{Re}(z_k), X(2*k+1) = \text{Im}(z_k), k = 0, 1, \dots, m.$

See [Example C-24](#).

Input and output data exchange the roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:n-1)
COMPLEX :: Y(0:m)
...some other code...
...assuming out-of-place transform...
Status = DftiSetValue( Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
...
Status = DftiComputeForward( Desc_Handle, X, Y )
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

$Y(k) = z_k, k = 0, 1, \dots, m.$

See [Example C-24a](#) and [Example C-25](#)

Input and output data exchange the roles in the backward transform.

- 3. DFTI_REAL_COMPLEX** for real domain, **DFTI_COMPLEX_COMPLEX** for conjugate-even domain. It is not used in the current version. See [Note in the “FFT Interface” section](#) for details. A typical usage is as follows:

```
// m = floor( n/2 )
COMPLEX :: X(0:m)
...some other code...
...inplace transform...
Status = DftiComputeForward( Desc_Handle, X )
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

That is, the imaginary parts of $X(j)$ are zero.

On output,

$Y(k) = z_k, k = 0, 1, \dots, m,$

where m is $\text{floor}(n/2)$.

Packed formats

The result of the forward transform (i.e. in the frequency-domain) of real data is represented in several possible packed formats: **Pack**, **Perm**, **CCS**, or **CCE**. The data can be packed due to the symmetry property of the FFT of a real data.

The **CCE** format stores the values of the first half of the output complex conjugate-even signal resulted from the forward FFT. Note that the one-dimensional signal stored in **CCE** format is one complex element longer. For multi-dimensional real transform, $n_1 * n_2 * n_3 * \dots * n_k$ the size of complex matrix in **CCE** format is $(n_1/2+1) * n_2 * n_3 * \dots * n_k$ for Fortran and $n_1 * n_2 * \dots * (n_k/2+1)$ for C.

The **CCS** format looks like the **CCE** format. It is the same format as **CCE** for one-dimensional transform. The **CCS** format is slightly different for multi-dimensional real transform. In **CCS** format, the output samples of the FFT are arranged as shown in [Table 11-9](#) for one-dimensional FFT and in [Table 11-10](#) for two-dimensional FFT.

$z(1,1)$ REz(1,2) IMz(1,2) ... REz(1,k) IMz(1,k)

If m is even, the last row in Pack format and the second row in Perm format is

$z(m/2+1,1)$ REz(m/2+1,2) IMz(m/2+1,2) ... REz(m/2+1,k) IMz(m/2+1,k)

The tables for two-dimensional FFT use Fortran-interface conventions. For C-interface specifics in storing packed data, see [Storage schemes](#) section below. See also [Table 11-15](#) and [Table 11-16](#) for examples of Fortran-interface and C-interface formats.

Number of user threads

Customer application can be parallelized by using the following techniques:

- You do not create threads in your application but specify the parallel mode within the FFT module of Intel MKL. See *Intel MKL User's Guide* for more information on how to do this. See also [Example C-26 in Appendix C](#).
- You create threads in the application yourself and have each thread perform all stages of FFT implementation, including descriptor initialization, FFT computation, and descriptor deallocation. In this case, each descriptor is used only within its corresponding thread. It is recommended to set single-threaded mode for Intel MKL. See [Example C-27 in Appendix C](#).
- You create threads in the application yourself after initializing all FFT descriptors. This implies that threading is employed for parallel FFT computation only, and the descriptors are released upon return from the parallel region. In this case, each descriptor is used only within its corresponding thread. It is obligatory to explicitly set the single-threaded mode for Intel MKL, otherwise, the actual number of threads may differ from one, because the `DftiCommitDescriptor` function is not in a parallel region. See [Example C-27a in Appendix C](#).

- d. You create threads in the application yourself after initializing the only FFT descriptor. This implies that threading is employed for parallel FFT computation only, and the descriptor is released upon return from the parallel region. In this case, each thread uses the same descriptor. See [Example C-28 in Appendix C](#).

In cases "a", "b", and "c", listed above, set the parameter `DFTI_NUMBER_OF_USER_THREADS` to 1 (its default value), since each particular descriptor instance is used only in a single thread.

In case "d", you must use the `DftiSetValue()` function to set the `DFTI_NUMBER_OF_USER_THREADS` to the actual number of FFT computation threads, because multiple threads will be using the same descriptor. If this setting is not done, your program will work incorrectly or fail, since the descriptor contains individual data for each thread.

WARNING.

- It is not recommended to simultaneously parallelize your program and employ the Intel MKL internal threading because this will slow down the performance. Note that in case "d" above, FFT computation is automatically initiated in a single-threading mode.
- You must not change the number of threads after the `DftiCommitDescriptor()` function completed FFT initialization.

Input and output distances

FFT interface in Intel MKL allows the computation of multiple number of transforms. Consequently, the user needs to be able to specify the data distribution of these multiple sets of data. This is accomplished by the distance between the first data element of the consecutive data sets. This parameter is obligatory if multiple number is more than one. The parameter is a value of `Integer` data type in Fortran and `MKL_LONG` data type in C. Data sets don't have any common elements. The following example illustrates the specification. Consider computing the forward FFT on three 32-length complex sequences stored in `X(0:31, 1)`, `X(0:31, 2)`, and `X(0:31, 3)`. Suppose the results are to be stored in the locations `Y(0:31, k)`, $k = 1, 2, 3$, of the array `Y(0:63, 3)`. Thus the input distance is 32, while the output distance is 64. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran. Here is the code fragment:

```
Complex :: X_2D(0:31,3), Y_2D(0:63, 3)
```

```

Complex :: X(96), Y(192)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
.....
Status = DftiCreateDescriptor(Desc_Handle, DFTI_SINGLE,

    DFTI_COMPLEX, 1, 32)
Status = DftiSetValue(Desc_Handle, DFTI_NUMBER_OF_TRANSFORMS, 3)
Status = DftiSetValue(Desc_Handle, DFTI_INPUT_DISTANCE, 32)
Status = DftiSetValue(Desc_Handle, DFTI_OUTPUT_DISTANCE, 64)
Status = DftiSetValue(Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(Desc_Handle)
Status = DftiComputeForward(Desc_Handle, X, Y)
Status = DftiFreeDescriptor(Desc_Handle)

```

Strides

In addition to supporting transforms of multiple number of datasets, FFT interface supports non-unit stride distribution of data within each data set. The parameter is an array of values of `Integer` data type in Fortran and `MKL_LONG` data type in C. Consider the following situation where a 32-length FFT is to be computed on the sequence x_j , $0 \leq j < 32$. The actual location of these values are in $X(5)$, $X(7)$, ..., $X(67)$ of an array $X(1:68)$. The stride accommodated by FFT interface consists of a displacement from the first element of the data array $L0$, (4 in this case), and a constant distance of consecutive elements $L1$ (2 in this case). Thus for the Fortran array X

$$x_j = X(1 + L0 + L1 * j) = X(5 + L1 * j).$$

This stride vector (4,2) is provided by a length-2 rank-1 integer array:

```
COMPLEX :: X(68)
INTEGER :: Stride(2)
.....
Status = DftiCreateDescriptor(Desc_Handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32)
Stride = (/ 4, 2 /)
Status = DftiSetValue(Desc_Handle, DFTI_INPUT_STRIDES, Stride)
Status = DftiSetValue(Desc_Handle, DFTI_OUTPUT_STRIDES, Stride)
Status = DftiCommitDescriptor(Desc_Handle)
Status = DftiComputeForward(Desc_Handle, X)
Status = DftiFreeDescriptor(Desc_Handle)
```

In general, for a d -dimensional transform, the stride is provided by a $d+1$ -length integer vector ($L0, L1, L2, \dots, Ld$) with the meaning:

$L0$ = displacement from the first array element
 $L1$ = distance between consecutive data elements in the first dimension
 $L2$ = distance between consecutive data elements in the second dimension
 $\dots = \dots$
 Ld = distance between consecutive data elements in the d -th dimension.

A d -dimensional data sequence

$X_{j_1, j_2, \dots, j_d}, 0 \leq j_i \leq J_i, 1 \leq i \leq d$

will be stored in the rank-1 array x by the mapping

$X_{j_1, j_2, \dots, j_d} = x(\text{first index} + L0 + j_1 L1 + j_2 L2 + \dots + j_d Ld).$

For multiple transforms, the value $L0$ applies to the first data sequence, and $Lj, j = 1, 2, \dots, d$ apply to all the data sequences.

In the case of a single one-dimensional sequence, $L1$ is simply the usual stride. The default setting of strides in the general multi-dimensional situation corresponds to the case where the sequences are distributed tightly into the array:

$$L1 = 1, L2 = J_1, L3 = J_1 J_2, \dots, Ld = \prod_{i=1}^{d-1} J_i$$

Both the input data and output data have a stride associated with it. The default is set in accordance with the data to be stored contiguously in memory in a way that is natural to the language.

Note that in case of a real FFT, where different formats are available, the default value is not the one that seems most natural for certain formats. For example, with the *CCE* format, strides are set by default to $L1 = 1$, $L2 = J1$ for a real transform regardless. However, for a complex matrix, slightly over half of the matrix is actually stored, and you should set strides to $L1 = 1$, $L2 = J1/2 + 1$. In case of an *in-place* transform with the *CCE* data format, even for a real array, you should set strides explicitly: $L1 = 1$, $L2 = (J1/2 + 1) * 2$.

See [Example C-23](#) as an illustration of how to use the configuration parameters discussed above. See [Storage schemes](#) and [Packed formats](#) on how to define arrays for different formats.

Ordering

It is well known that a number of FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus permission of scrambled order is attractive if it leads to higher performance. The following options are available in Intel MKL:

- `DFTI_ORDERED`: Forward transform data ordered, backward transform data ordered (default option).
- `DFTI_BACKWARD_SCRAMBLED`: Forward transform data ordered, backward transform data scrambled.

[Table 11-17](#) tabulates the effect on this configuration setting.

Table 11-17 Scrambled Order Transform

	DftiComputeForward	DftiComputeBackward
DFTI_ORDERING	Input → Output	Input → Output
<code>DFTI_ORDERED</code>	ordered → ordered	ordered → ordered
<code>DFTI_BACKWARD_SCRAMBLED</code>	ordered → scrambled	scrambled → ordered

Note that meaning of the latter two options are "allow scrambled order if practical." There are situations where in fact allowing out of order data gives no performance advantage, and thus an implementation may choose to ignore the suggestion. Strictly speaking, the normal order is also a scrambled order, the trivial one.

Transposition

This is an option that allows for the result of a high-dimensional transform to be presented in a transposed manner. The default setting is `DFTI_NONE` and can be set to `DFTI_ALLOW`. Similar to that of scrambled order, sometimes in higher dimension transform, performance can be gained if the result is delivered in a transposed manner. FFT interface offers an option for the output be returned in a transposed form if performance gain is possible. Since the generic stride specification is naturally suited for representation of transposition, this option allows the strides for the output to be possibly different from those originally specified by the user. Consider an example where a two-dimensional result

$$Y_{j_1, j_2}, \quad 0 \leq j_i < n_i,$$

is expected. Originally the user specified that the result be distributed in the (flat) array Y in with generic strides $L_1 = 1$ and $L_2 = n_1$. With the transposition option, the computation may actually return the result into Y with stride $L_1 = n_2$ and $L_2 = 1$. These strides can be obtained from an appropriate inquiry function. Note also that in dimension 3 and above, transposition means an arbitrary permutation of the dimension.

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

NOTE. These functions are available only for the Linux* and Windows* operating systems.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL [FFT functions](#), described earlier in this chapter. Refer there for details not explained in this section.

[Table 11-18](#) lists cluster FFT functions implemented in Intel MKL:

Table 11-18 Cluster FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptorDM	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The cluster FFT functions described later in this section are provided with Fortran and C interfaces. Fortran stands for Fortran 95.

Cluster FFT computation is performed by [DftiComputeForwardDM](#) and [DftiComputeBackwardDM](#) functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates local part of the input data, i.e. some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` in C/C++ or `MPI_INIT` in Fortran (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling [DftiCreateDescriptorDM](#).
3. Specify one of several values of configuration parameters by one or more calls to [DftiSetValueDM](#).
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling [DftiGetValueDM](#).
5. Initialize the descriptor for the FFT computation by calling [DftiCommitDescriptorDM](#).
6. Create arrays for local parts of input and output data and fill the local part of input data with values (For more information, see [Distributing Data among Processes](#).)
7. Compute the transform by calling [DftiComputeForwardDM](#) or [DftiComputeBackwardDM](#).
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling [DftiFreeDescriptorDM](#).
10. Finalize communication through MPI by calling `MPI_Finalize` in C/C++ or `MPI_FINALIZE` in Fortran (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the “[Examples for Cluster FFT Functions](#)” section in Appendix C illustrate cluster FFT computations.

Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order in C/C++ and in the column-major order in Fortran. For example, a two-dimensional matrix *A* of size (m, n) is stored in a vector *B* of size $m*n$ so that

- $B[i*n+j]=A[i][j]$ in C/C++ ($i=0, \dots, m-1, j=0, \dots, n-1$)

- $B(j \cdot m + i) = A(i, j)$ in Fortran ($i=1, \dots, m, j=1, \dots, n$).

NOTE. Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with $\text{Lengths}=(m, n, l)$ can be computed over an array $A[m][n][l]$ in C/C++ or $A(m, n, l)$ in Fortran.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able to do this, see sections below on how the virtual global array is composed of the local ones.

Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C and the last one in Fortran. If the global array is two-dimensional, in C, it gives each process several consecutive rows. The term “rows” will be used regardless of the array dimension and programming language. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size (11,15,12), the processes may store local arrays of sizes (6,15,12) and (5,15,12), respectively.

If p is the number of MPI processes and the matrix of a transform to be computed has size (m, n, l) , in C, each MPI process works with local data array of size (m_q, n, l) , where $\sum m_q = m$, $q=0, \dots, p-1$. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the `DftiGetValueDM` function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If A is a global array and L is the appropriate local array, then

- `L[i][j][k]=A[i+cdft_local_start_x][j][k]`, where $i=0, \dots, m_q-1, j=0, \dots, n-1, k=0, \dots, l-1$ for C/C++
- `L(i,j,k)=A(i,j,k+cdft_local_start_x-1)`, where $i=1, \dots, m_q, j=1, \dots, n, k=1, \dots, l$ for Fortran.

Example C-29 in Appendix C shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in Table 11-19:

Table 11-19 Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	CDFT_LOCAL_NX	CDFT_LOCAL_OUT_NX
Elements shift in input array	CDFT_LOCAL_START_X	CDFT_LOCAL_OUT_START_X
Number of elements in output array	CDFT_LOCAL_OUT_NX	CDFT_LOCAL_NX
Elements shift in output array	CDFT_LOCAL_OUT_START_X	CDFT_LOCAL_START_X

Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data

elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table 11-20](#)), it must have the same size as the local arrays. [Example C-30](#) in Appendix C illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation effected with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory:
`examples/cdftc/examples_support.c` for C/C++ and
`examples/cdftf/examples_support.f90` for Fortran.

Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions in C/C++ or of the last two dimensions in Fortran must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

Cluster FFT Interface

To use the cluster FFT functions, you need to access the module `MKL_CDFT` through the "use" statement in Fortran; or access the header file `mk1_cdft.h` through "include" in C/C++.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR_DM`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- Fortran:

```
INCLUDE "mpif.h"
```

(for some MPI versions, "mpif90.h" header may be used instead).

- C/C++:

```
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel MKL:

- 1. Descriptor Manipulation.** There are three functions in this category. The `DftiCreateDescriptorDM` function creates an FFT descriptor whose storage is allocated dynamically. The `DftiCommitDescriptorDM` function "commits" the descriptor to all its settings. The `DftiFreeDescriptorDM` function frees up the memory allocated for the descriptor.
- 2. FFT Computation.** There are two functions in this category. The `DftiComputeForwardDM` function performs the forward FFT computation, and the `DftiComputeBackwardDM` function performs the backward FFT computation.
- 3. Descriptor Configuration.** There are two functions in this category. The `DftiSetValueDM` function sets one specific configuration value to one of the many configuration parameters. The `DftiGetValueDM` function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

CreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, size)
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, sizes)
```

C/C++:

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size );
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes );
```

Input Parameters

<i>comm</i>	MPI communicator, e.g. <code>MPI_COMM_WORLD</code> .
<i>v1</i>	Precision of the transform.
<i>v2</i>	Type of the forward domain. Must be <code>DFTI_COMPLEX</code> for complex-to-complex transforms or <code>DFTI_REAL</code> for real-to-complex transforms.
<i>dim</i>	Dimension of the transform.
<i>size</i>	Length of the transform in a one-dimensional case.
<i>sizes</i>	Lengths of the transform in a multi-dimensional case.

Output Parameters

<i>handle</i>	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.
---------------	-----------------------------------------------------------------------------------------------------------------------------------------------------

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created

descriptor. This function is slightly different from the "initialization" function `DftiCommitDescriptorDM` in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function `DftiSetValueDM`.

The value of the parameter *vl* is specified through named constants `DFTI_SINGLE` and `DFTI_DOUBLE`. It corresponds to precision of input data, output data, and computation. A setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The parameter *dim* is a simple positive integer indicating the dimension of the transform.

In C/C++, for one-dimensional transforms, length is a single integer value of the parameter *size* having type `MKL_LONG`; for multi-dimensional transforms, length is supplied with the parameter *sizes*, which is an array of integers having type `MKL_LONG`. In Fortran, length is an integer or an array of integers.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. In this case, the pointer to the created descriptor handle is stored in *handle*. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCreateDescriptorDM
    INTEGER(4) FUNCTION DftiCreateDescriptorDMn(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiCreateDescriptorDM1(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L
    END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
    enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,MKL_LONG,...);
```

CommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptorDM(handle)
```

C/C++:

```
status = DftiCommitDescriptorDM(handle);
```

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The `DftiCommitDescriptorDM` function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation](#)).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCommitDescriptorDM
    INTEGER(4) FUNCTION DftiCommitDescriptorDM(handle);
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
    END FUNCTION
END INTERFACE
```

```
/* C/C++ prototype */
```

```
MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

FreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptorDM(handle)
```

C/C++:

```
status = DftiFreeDescriptorDM(&handle);
```

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

Output Parameters

handle The descriptor handle. Memory allocated for the handle is released on output.

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiFreeDescriptorDM
  INTEGER(4) FUNCTION DftiFreeDescriptorDM(handle)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
  END FUNCTION
END INTERFACE

/* C/C++ prototype */

MKL_LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);
```

FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

ComputeForwardDM

Computes the forward FFT.

Syntax

Fortran:

```
Status = DftiComputeForwardDM(handle, in_X, out_X)
Status = DftiComputeForwardDM(handle, in_out_X)
```

C/C++:

```
status = DftiComputeForwardDM(handle, in_X, out_X);
status = DftiComputeForwardDM(handle, in_out_X);
```

Input Parameters

<i>handle</i>	The descriptor handle.
<i>in_X, in_out_X</i>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

<i>out_X, in_out_X</i>	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.
------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION. Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE. You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiComputeForwardDM
    INTEGER(4) FUNCTION DftiComputeForwardDM(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeForwardDM
    INTEGER(4) FUNCTION DftiComputeForwardDMi(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMi
    INTEGER(4) FUNCTION DftiComputeForwardDMs(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeForwardDMs
    INTEGER(4) FUNCTION DftiComputeForwardDMis(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMis
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

ComputeBackwardDM

Computes the backward FFT.

Syntax

Fortran:

```
Status = DftiComputeBackwardDM(handle, in_X, out_X)
```

```
Status = DftiComputeBackwardDM(handle, in_out_X)
```

C/C++:

```
status = DftiComputeBackwardDM(handle, in_X, out_X);
```

```
status = DftiComputeBackwardDM(handle, in_out_X);
```

Input Parameters

handle

The descriptor handle.

in_X, in_out_X

Local part of input data. Array of complex values. Refer to the [Distributing Data among Processes](#) section on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X

Local part of output data. Array of complex values. Refer to the [Distributing Data among Processes](#) section on how to allocate the array.

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION. Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE. You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);

```

Descriptor Configuration Functions

There are two functions in this category: the value setting function [DftiSetValueDM](#) sets one particular configuration parameter to an appropriate value, the value getting function [DftiGetValueDM](#) reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) subsection in the “FFT Functions” section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `MKL_LONG` in C/C++ and `INTEGER(4)` in Fortran. The exact type of the configuration parameters being floating-point scalars is `float` or `double` in C/C++ and `REAL(4)` or `REAL(8)` in Fortran. The configuration parameters whose values are named constants have the `enum` type in C/C++ and `INTEGER` in Fortran. They are defined in the `mk1_cdft.h` header file in C/C++ and `MKL_CDFT` module in Fortran.

Names of the configuration parameters specific to the cluster FFT interface have prefix `CDFT`.

SetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValueDM (handle, param, value)
```

C/C++:

```
status = DftiSetValueDM (handle, param, value);
```

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be set up in the descriptor handle. See Table 11-20 for the list of available parameters.
<i>value</i>	Value of the parameter.

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of the setting. See [Table 11-6](#) for possible values of the parameters that are named constants.

Table 11-20 Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.	1.0
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.	1.0
DFTI_PLACEMENT	Named constant	Placement of the computation result.	DFTI_INPLACE
DFTI_ORDERING	Named constant	Scrambling of data order.	DFTI_ORDERED
DFTI_WORKSPACE	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).
DFTI_PACKED_FORMAT	Named constant	Packed format, real data.	<ul style="list-style-type: none"><code>DFTI_PACKED_FORMAT</code> — default and the only available value for <code>onedim</code> transforms

Parameter Name	Data Type	Description	Default Value
			<ul style="list-style-type: none"> <code>DFTI_NO_TRANSFORM</code> — default and the only available value for <code>num_transforms</code>

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiSetValueDM
    INTEGER(4) FUNCTION DftiSetValueDM(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v
    END FUNCTION
    INTEGER(4) FUNCTION DftiSetValueDMd(h, p, v)

        INTEGER(4) :: p
        COMPLEX(4) :: v(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiSetValueDMdw(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p
        COMPLEX(8) :: v(*)
    END FUNCTION
```

END INTERFACE

```
/* C/C++ prototype */
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

GetValueDM

Gets the value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValueDM(handle, param, value)
```

C/C++:

```
status = DftiGetValueDM(handle, param, &value);
```

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be retrieved from the descriptor. See Table 11-21 for the list of available parameters.

Output Parameters

<i>value</i>	Value of the parameter.
--------------	-------------------------

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in

the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table 11-6](#).

Table 11-21 Retrievable Configuration Parameters

Parameter Name	Data Type	Description
DFTI_PRECISION	Named constant	Precision of computation, input data and output data.
DFTI_DIMENSION	Integer scalar	Dimension of the transform
DFTI_LENGTHS	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.
DFTI_PLACEMENT	Named constant	Placement of the computation result.
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms, has the value of <code>DFTI_COMPLEX</code> or <code>DFTI_REAL</code> .
DFTI_ORDERING	Named constant	Scrambling of data order.
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes .

Parameter Name	Data Type	Description
<code>CFFT_LOCAL_NX</code>	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes .
<code>CFFT_LOCAL_OUT_X_START</code>	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes .
<code>CFFT_LOCAL_OUT_NX</code>	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes .

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiGetValueDM
    INTEGER(4) FUNCTION DftiGetValueDM(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v
    END FUNCTION
    INTEGER(4) FUNCTION DftiGetValueDMar(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiGetValueDMd(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p
        REAL(8) :: v
    END FUNCTION
    INTEGER(4) FUNCTION DftiGetValueDMs(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p
        REAL(4) :: v
    END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix "CDFT" in names. [Table 11-22](#) lists error codes that the cluster FFT functions may return.

Table 11-22 Error Codes that Cluster FFT Functions Return

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error.
<code>DFTI_MEMORY_ERROR</code>	Usually associated with memory allocation.
<code>DFTI_INVALID_CONFIGURATION</code>	Invalid settings of one or more configuration parameters.
<code>DFTI_INCONSISTENT_CONFIGURATION</code>	Inconsistent configuration or input parameters.
<code>DFTI_NUMBER_OF_THREADS_ERROR</code>	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
<code>DFTI_MULTITHREADED_ERROR</code>	Usually associated with a value that OMP routines return in case of errors.
<code>DFTI_BAD_DESCRIPTOR</code>	Descriptor is unusable for computation.
<code>DFTI_UNIMPLEMENTED</code>	Unimplemented legitimate settings; implementation dependent.
<code>DFTI_MKL_INTERNAL_ERROR</code>	Internal library error.
<code>DFTI_1D_LENGTH_EXCEEDS_INT32</code>	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).
<code>CDFT_SPREAD_ERROR</code>	Data cannot be distributed (For more information, see Distributing Data among Processes.)
<code>CDFT_MPI_ERROR</code>	MPI error. Occurs when calling MPI.

PBLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the PBLAS (Parallel Basic Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using for vector-vector, matrix-vector and matrix-matrix operations with the aim of simplifying the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- [PBLAS Level 1 Routines](#) (distributed vector-vector operations)
- [PBLAS Level 2 Routines](#) (distributed matrix-vector operations)
- [PBLAS Level 3 Routines](#) (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to different character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

NOTE. PBLAS routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. Intel MKL version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on PBLAS routines and related information see http://www.netlib.org/scalapack/html/pblas_qref.html.

Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and

its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. An example of an array descriptor structure is given in [Table 12-1](#).

Table 12-1 Content of the array descriptor for dense matrices

Array Element #	Name	Definition
1	<i>dtype</i>	Descriptor type (=1 for dense matrices)
2	<i>ctxt</i>	BLACS context handle for the process grid
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>lld</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr()* and *LOCc()*, respectively. To compute these numbers, you can use the ScaLAPACK tool routine *numroc*.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray *sub(A)*, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of <i>sub(A)</i>
<i>n</i>	The number of columns of <i>sub(A)</i>
<i>a</i>	A pointer to the local array containing the entire global array <i>A</i>
<i>ia</i>	The row index of <i>sub(A)</i> in the global array
<i>ja</i>	The column index of <i>sub(A)</i> in the global array
<i>desca</i>	The array descriptor for the global array <i>A</i>

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see http://www.netlib.org/scalapack/html/pblas_qref.html).

Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see [Routine Naming Conventions in Chapter 2](#)). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter *p* that stands for "parallel".

PBLAS routine names have the following structure:

`p <character> <name> <mod> ()`

The `<character>` field indicates the Fortran data type:

<code>s</code>	real, single precision
<code>c</code>	complex, single precision
<code>d</code>	real, double precision
<code>z</code>	complex, double precision

Some routines and functions can have combined character codes, such as `sc` or `dz`.

For example, the function `pscsum` uses a complex input array and returns a real value.

The `<name>` field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines `p?dot`, `p?swap`, `p?copy` compute a vector dot product, vector swap, and copy vector, respectively.

In PBLAS level 2 and 3, `<name>` reflects the matrix argument type:

<code>ge</code>	general matrix
<code>sy</code>	symmetric matrix
<code>he</code>	Hermitian matrix
<code>tr</code>	triangular matrix

In PBLAS level 3, the `<name>=tran` indicates the transposition of the matrix.

The `<mod>` field, if present, provides additional details of the operation. PBLAS level 1 names can have the following characters in the `<mod>` field:

<code>c</code>	conjugated vector
<code>u</code>	unconjugated vector

PBLAS level 2 names can have the following additional characters in the `<mod>` field:

<code>mv</code>	matrix-vector product
<code>sv</code>	solving a system of linear equations with matrix-vector operations
<code>r</code>	rank-1 update of a matrix
<code>r2</code>	rank-2 update of a matrix.

PBLAS level 3 names can have the following additional characters in the `<mod>` field:

<code>mm</code>	matrix-matrix product
<code>sm</code>	solving a system of linear equations with matrix-matrix operations
<code>rk</code>	rank- k update of a matrix

`r2k` rank- $2k$ update of a matrix.

The examples below illustrate how to interpret PBLAS routine names:

<code>pddot</code>	<code><p> <d> <dot></code> : double-precision real distributed vector-vector dot product
<code>pcdotc</code>	<code><p> <c> <dot> <c></code> : complex distributed vector-vector dot product, conjugated
<code>pscasum</code>	<code><p> <sc> <asum></code> : sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
<code>pcdotu</code>	<code><p> <c> <dot> <u></code> : distributed vector-vector dot product, unconjugated, complex
<code>psgemv</code>	<code><p> <s> <ge> <mv></code> : distributed matrix-vector product, general matrix, single precision
<code>pztrmm</code>	<code><p> <z> <tr> <mm></code> : distributed matrix-matrix product, triangular matrix, double-precision complex.

PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions, which perform distributed vector-vector operations. [Table 12-1](#) lists the PBLAS Level 1 routine groups and the data types associated with them.

Table 12-1 PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
<code>p?amax</code>	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
<code>p?asum</code>	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
<code>p?axpy</code>	s, d, c, z	Calculates distributed vector-scalar product
<code>p?copy</code>	s, d, c, z	Copies a distributed vector
<code>p?dot</code>	s, d	Calculates a dot product of two distributed real vectors
<code>p?dotc</code>	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated

Routine or Function Group	Data Types	Description
<code>p?dotu</code>	c, z	Calculates a dot product of two distributed complex vectors
<code>p?nrm2</code>	s, d, sc, dz	Calculates the 2-norm (Euclidean norm) of a distributed vector
<code>p?scal</code>	s, d, c, z, cs, zd	Calculates a product of a distributed vector by a scalar
<code>p?swap</code>	s, d, c, z	Swaps two distributed vectors

p?amax

Computes the global index of the element of a distributed vector with maximum absolute value.

Syntax

```
call psamax(n, amax, indx, x, ix, jx, descx, incx)
call pdamax(n, amax, indx, x, ix, jx, descx, incx)
call pcamax(n, amax, indx, x, ix, jx, descx, incx)
call pzamax(n, amax, indx, x, ix, jx, descx, incx)
```

Description

The functions `p?amax` compute global index of the maximum element in absolute value of a distributed vector `sub(x)`,

where `sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx=m_x`, and `X(ix: ix+n-1, jx)` if `incx=1`.

Input Parameters

`n` (global) INTEGER. The length of distributed vector `sub(x)`, $n \geq 0$.

`x` (local) REAL for `psamax`
DOUBLE PRECISION for `pdamax`
COMPLEX for `pcamax`

DOUBLE COMPLEX for pzamax
 Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$.
 This array contains the entries of the distributed vector
 $sub(x)$.

ix, jx (global) INTEGER. The row and column indices in the
 distributed matrix x indicating the first row and the first
 column of the submatrix $sub(X)$, respectively.

descx (global and local) INTEGER array of dimension 8. The array
 descriptor of the distributed matrix x .

incx (global) INTEGER. Specifies the increment for the elements
 of $sub(x)$. Only two values are supported, namely 1 and
 m_x . *incx* must not be zero.

Output Parameters

amax (global) REAL for psamax.
 DOUBLE PRECISION for pdamax.
 COMPLEX for pcamax.
 DOUBLE COMPLEX for pzamax.
 Maximum absolute value (magnitude) of elements of the
 distributed vector only in its scope.

indx (global) INTEGER. The global index of the maximum element
 in absolute value of the distributed vector $sub(x)$ only in
 its scope.

p?asum

*Computes the sum of magnitudes of elements of
 a distributed vector.*

Syntax

```
call psasum(n, asum, x, ix, jx, descx, incx)
call pscasum(n, asum, x, ix, jx, descx, incx)
call pdasum(n, asum, x, ix, jx, descx, incx)
call pdzasum(n, asum, x, ix, jx, descx, incx)
```

Description

The functions `p?asum` compute the sum of the magnitudes of elements of a distributed vector `sub(x)`,

where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
<code>x</code>	(local) REAL for <code>psasum</code> DOUBLE PRECISION for <code>pdasum</code> COMPLEX for <code>pscasum</code> DOUBLE COMPLEX for <code>pdzasum</code> Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

<code>asum</code>	(local) REAL for <code>psasum</code> and <code>pscasum</code> . DOUBLE PRECISION for <code>pdasum</code> and <code>pdzasum</code> Contains the sum of magnitudes of elements of the distributed vector only in its scope.
-------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

p?axpy

Computes a distributed vector-scalar product and adds the result to a distributed vector.

Syntax

```
call psaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The p?axpy routines perform the following operation with distributed vectors:

$\text{sub}(y) := \text{sub}(y) + a * \text{sub}(x)$

where:

a is a scalar;

$\text{sub}(x)$ and $\text{sub}(y)$ are n -element distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
a	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Specifies the scalar a .
x	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$.

	This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix y indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by $\text{sub}(y) := \text{sub}(y) + a*\text{sub}(x)$.
----------	---------------------------------------------------------------------

p?copy

Copies one distributed vector to another vector.

Syntax

```
call pscopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pccopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The p?copy routines perform a copy operation with distributed vectors defined as

$\text{sub}(y) = \text{sub}(x),$

where $\text{sub}(x)$ and $\text{sub}(y)$ are n -element distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
x	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
$descx$	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .

<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the distributed vector $\text{sub}(x)$.
----------	---------------------------------------------------------

p?dot

Computes the dot product of two distributed real vectors.

Syntax

```
call psdot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pddot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

$$\text{dot} = \text{sub}(x)' * \text{sub}(y)$$

where $\text{sub}(x)$ and $\text{sub}(y)$ are n -element distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;
`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<code>x</code>	(local) REAL for psdot DOUBLE PRECISION for pddot Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
<code>y</code>	(local) REAL for psdot DOUBLE PRECISION for pddot Array, DIMENSION $(jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively.
<code>descy</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix Y .
<code>incy</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

<code>dot</code>	(local) REAL for psdot DOUBLE PRECISION for pddot
------------------	------------------------------------------------------

Dot product of `sub(x)` and `sub(y)` only in their scope.

p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

Syntax

```
call pcdotc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdorc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The `p?dotu` functions compute the dot product `dotc` of two distributed vectors one of them is conjugated:

$$dotc = \text{conjg}(\text{sub}(x)') * \text{sub}(y)$$

where `sub(x)` and `sub(y)` are n -element distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<code>x</code>	(local) COMPLEX for <code>pcdotc</code> DOUBLE COMPLEX for <code>pzdorc</code> Array, DIMENSION $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

<i>y</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Array, DIMENSION (jy-1)*m_y + iy+(n-1)*abs(incy)). This array contains the entries of the distributed vector sub(y).
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix sub(<i>Y</i>), respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of sub(y). Only two values are supported, namely 1 and m_y. incy must not be zero.

Output Parameters

<i>dotc</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Dot product of sub(x) and sub(y) only in their scope.
-------------	------------------------------------------------------------------------------------------------------------------

p?dotu

Computes the dot product of two distributed complex vectors.

Syntax

```
call pcdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The p?dotu functions compute the dot product *dotu* of two distributed vectors defined as

$$dotu = sub(x)' * sub(y)$$

where sub(x) and sub(y) are *n*-element distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>dotu</i>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Dot product of $sub(x)$ and $sub(y)$ only in their scope.
-------------	----------------------------------------------------------------------------------------------------------------------

p?norm2

Computes the Euclidean norm of a distributed vector.

Syntax

```
call psnorm2(n, norm2, x, ix, jx, descx, incx)
call pdnorm2(n, norm2, x, ix, jx, descx, incx)
call pscnorm2(n, norm2, x, ix, jx, descx, incx)
call pdznorm2(n, norm2, x, ix, jx, descx, incx)
```

Description

The p?norm2 functions compute the Euclidean norm of a distributed vector $\text{sub}(x)$, where $\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

n	(global) INTEGER. The length of distributed vector $\text{sub}(x)$, $n \geq 0$.
x	(local) REAL for psnorm2 DOUBLE PRECISION for pdnorm2 COMPLEX for pscnorm2 DOUBLE COMPLEX for pdznorm2 Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
$descx$	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
$incx$	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

norm2 (local) REAL for psnrm2 and pscnrm2.
 DOUBLE PRECISION for pdnrm2 and pdznrm2
 Contains the Euclidean norm of a distributed vector only in its scope.

p?scal

Computes a product of a distributed vector by a scalar.

Syntax

```
call psscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pzscal(n, a, x, ix, jx, descx, incx)
call pcsscal(n, a, x, ix, jx, descx, incx)
call pzdscale(n, a, x, ix, jx, descx, incx)
```

Description

The p?scal routines multiplies a n -element distributed vector $\text{sub}(x)$ by the scalar a :

$\text{sub}(x) = a * \text{sub}(x),$

where $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$.

Input Parameters

n (global) INTEGER. The length of distributed vector $\text{sub}(x)$, $n \geq 0$.

a (global) REAL for psscal and pcsscal
 DOUBLE PRECISION for pdscal and pzdscale
 COMPLEX for pcscal
 DOUBLE COMPLEX for pzscal
 Specifies the scalar a .

<i>x</i>	(local) REAL for psscal DOUBLE PRECISION for pdscal COMPLEX for pcscal and pcsscal DOUBLE COMPLEX for pzscal and pzdscale Array, DIMENSION (<i>jx</i> -1)* <i>m_x</i> + <i>ix</i> +(<i>n</i> -1)*abs(<i>incx</i>)). This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(X)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by the updated distributed vector <i>sub(x)</i>
----------	-------------------------------------------------------------

p?swap

Swaps two distributed vectors.

Syntax

```
call psswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

Given two distributed vectors *sub(x)* and *sub(y)*, the p?swap routines return vectors *sub(y)* and *sub(x)* swapped, each replacing the other.

Here *sub(x)* denotes *X(ix, jx:jx+n-1)* if *incx=m_x*, and *X(ix: ix+n-1, jx)* if *incx= 1*;
sub(y) denotes *Y(iy, jy:jy+n-1)* if *incy=m_y*, and *Y(iy: iy+n-1, jy)* if *incy= 1*.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by distributed vector $sub(y)$.
----------	----------------------------------------------

y Overwritten by distributed vector `sub(x)`.

PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. [Table 12-2](#) lists the PBLAS Level 2 routine groups and the data types associated with them.

Table 12-2 PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
<code>p?gemv</code>	s, d, c, z	Matrix-vector product using a distributed general matrix
<code>p?ger</code>	s, d	Rank-1 update of a distributed general matrix
<code>p?gerc</code>	c, z	Rank-1 update (conjugated) of a distributed general matrix
<code>p?geru</code>	c, z	Rank-1 update (unconjugated) of a distributed general matrix
<code>p?hemv</code>	c, z	Matrix-vector product using a distributed Hermitian matrix
<code>p?her</code>	c, z	Rank-1 update of a distributed Hermitian matrix
<code>p?her2</code>	c, z	Rank-2 update of a distributed Hermitian matrix
<code>p?symv</code>	s, d	Matrix-vector product using a distributed symmetric matrix
<code>p?syr</code>	s, d	Rank-1 update of a distributed symmetric matrix
<code>p?syr2</code>	s, d	Rank-2 update of a distributed symmetric matrix
<code>p?trmv</code>	s, d, c, z	Distributed matrix-vector product using a triangular matrix
<code>p?trsv</code>	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

p?gemv

Computes a distributed matrix-vector product using a general matrix

Syntax

```
call psgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

call pdgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

call pcgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

call pzgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)
```

Description

The p?gemv routines perform a distributed matrix-vector operation defined as

$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$

or

$\text{sub}(y) := \alpha * \text{sub}(A)' * \text{sub}(x) + \beta * \text{sub}(y),$

or

$\text{sub}(y) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(x) + \beta * \text{sub}(y),$

where

α and β are scalars,

$\text{sub}(A)$ is a m -by- n submatrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1),$

$\text{sub}(x)$ and $\text{sub}(y)$ are subvectors.

When $\text{trans} = 'N'$ or $'n'$, $\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m_x$, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$, $\text{sub}(y)$ denotes $Y(\text{iy}, \text{jy}:\text{jy}+m-1)$ if $\text{incy} = m_y$, and $Y(\text{iy}:\text{iy}+m-1, \text{jy})$ if $\text{incy} = 1$.

When $\text{trans} = 'T'$ or $'t'$, or $'C'$, or $'c'$, $\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+m-1)$ if $\text{incx} = m_x$, and $X(\text{ix}:\text{ix}+m-1, \text{jx})$ if $\text{incx} = 1$, $\text{sub}(y)$ denotes $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$ if $\text{incy} = m_y$, and $Y(\text{iy}:\text{iy}+m-1, \text{jy})$ if $\text{incy} = 1$.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y)$; if <i>trans</i> = 'T' or 't', then $\text{sub}(y) := \alpha * \text{sub}(A)^T * \text{sub}(x) + \beta * \text{sub}(y)$; if <i>trans</i> = 'C' or 'c', then $\text{sub}(y) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(x) + \beta * \text{sub}(y)$.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja</i> + <i>n</i> -1)). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv

	<p>Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$ when $trans = 'N'$ or $'n'$, and $(jx-1)*m_x + ix+(m-1)*abs(incx)$ otherwise.</p> <p>This array contains the entries of the distributed vector $sub(x)$.</p>
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
<i>beta</i>	<p>(global) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv</p> <p>Specifies the scalar $beta$. When $beta$ is set to zero, then $sub(y)$ need not be set on input.</p>
<i>y</i>	<p>(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv</p> <p>Array, DIMENSION $(jy-1)*m_y + iy+(m-1)*abs(incy)$ when $trans = 'N'$ or $'n'$, and $(jy-1)*m_y + iy+(n-1)*abs(incy)$ otherwise.</p> <p>This array contains the entries of the distributed vector $sub(y)$.</p>
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix y indicating the first row and the first column of the submatrix $sub(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

y Overwritten by the updated distributed vector `sub(y)`.

p?ger

Performs a rank-1 update of a distributed general matrix.

Syntax

```
call psger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

```
call pdger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

Description

The `p?ger` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \text{sub}(A),$$

where:

α is a scalar,

$\text{sub}(A)$ is a m -by- n distributed general matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$,

$\text{sub}(x)$ is an m -element distributed vector, $\text{sub}(y)$ is an n -element distributed vector,

$\text{sub}(x)$ denotes $X(ix, jx:jx+m-1)$ if $incx = m_x$, and $X(ix: ix+m-1, jx)$ if $incx = 1$,

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

m (global) INTEGER. Specifies the number of rows of the distributed matrix `sub(A)`, $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distributed matrix `sub(A)`, $n \geq 0$.

α (global) REAL for `psger`
DOUBLE REAL for `pdger`
Specifies the scalar α .

<i>x</i>	<p>(local) REAL for psgcr DOUBLE REAL for pdger Array, DIMENSION at least $(j_x-1)*m_x + i_x + (m-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.</p>
<i>ix, jx</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(x)$, respectively.</p>
<i>descx</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i>.</p>
<i>incx</i>	<p>(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x. <i>incx</i> must not be zero.</p>
<i>y</i>	<p>(local) REAL for psgcr DOUBLE REAL for pdger Array, DIMENSION at least $(j_y-1)*m_y + i_y + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.</p>
<i>iy, jy</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(y)$, respectively.</p>
<i>descy</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i>.</p>
<i>incy</i>	<p>(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y. <i>incy</i> must not be zero.</p>
<i>a</i>	<p>(local) REAL for psgcr DOUBLE REAL for pdger Array, DIMENSION $(lld_a, LOCq(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $sub(A)$.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$, respectively.</p>

desca (global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a Overwritten by the updated distributed matrix `sub(A)`.

p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

Syntax

```
call pcgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

```
call pzgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

Description

The `p?gerc` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(y)') + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *m*-by-*n* distributed general matrix, `sub(A) = A(ia:ia+m-1, ja:ja+n-1)`,

`sub(x)` is an *m*-element distributed vector, `sub(y)` is an *n*-element distributed vector,

`sub(x)` denotes `X(ix, jx:jx+m-1)` if `incx = m_x`, and `X(ix: ix+m-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

Input Parameters

m (global) `INTEGER`. Specifies the number of rows of the distributed matrix `sub(A)`, $m \geq 0$.

n (global) `INTEGER`. Specifies the number of columns of the distributed matrix `sub(A)`, $n \geq 0$.

alpha (global) `COMPLEX` for `pcgerc`

	DOUBLE COMPLEX for pzgerc Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least $(lld_a, LOCq(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $sub(A)$.

<i>ia, ja</i>	(global) <code>INTEGER</code> . The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <code>A</code> .

Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix <code>sub(A)</code> .
----------	---------------------------------------------------------------------

p?geru

Performs a rank-1 update (unconjugated) of a distributed general matrix.

Syntax

```
call pcgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)

call pzgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

Description

The `p?geru` routines perform a matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)^T + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *m*-by-*n* distributed general matrix, `sub(A)=A(ia:ia+m-1, ja:ja+n-1)`,

`sub(x)` is an *m*-element distributed vector, `sub(y)` is an *n*-element distributed vector,

`sub(x)` denotes `X(ix, jx:jx+m-1)` if `incx = m_x`, and `X(ix: ix+m-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

Input Parameters

<i>m</i>	(global) <code>INTEGER</code> . Specifies the number of rows of the distributed matrix <code>sub(A)</code> , $m \geq 0$.
----------	---------------------------------------------------------------------------------------------------------------------------

<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru Array, DIMENSION at least $(j_x-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru Array, DIMENSION at least $(j_y-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru

Array, DIMENSION at least $(lld_a, LOCq(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $sub(A)$.

ia, ja (global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A .

Output Parameters

a Overwritten by the updated distributed matrix $sub(A)$.

p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

Syntax

```
call pchemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)

call pzhemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)
```

Description

The p?hemv routines perform a distributed matrix-vector operation defined as

$$sub(y) := \alpha * sub(A) * sub(x) + \beta * sub(y),$$

where:

alpha and *beta* are scalars,

$sub(A)$ is a n -by- n Hermitian distributed matrix, $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$sub(x)$ and $sub(y)$ are distributed vectors.

$sub(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix: ix+n-1, jx)$ if $incx = 1$,

$sub(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.</p>
<i>alpha</i>	<p>(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION (<i>lld_a</i>, $\text{LOCq}(ja+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry when <i>uplo</i> = 'U' or 'u', the n-by-n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the n-by-n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>x</i>	<p>(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION at least $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$.</p>

	This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector $\text{sub}(y)$.
----------	-----------------------------------------------------------------

p?her

Performs a rank-1 update of a distributed Hermitian matrix.

Syntax

```
call pcher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca )
call pzher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca )
```

Description

The p?her routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(x)') + \text{sub}(A),$$

where:

α is a real scalar,

$\text{sub}(A)$ is a n -by- n distributed Hermitian matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ is distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix:ix+n-1, jx)$ if $incx = 1$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for pcher DOUBLE REAL for pzher Specifies the scalar α .
<i>x</i>	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher

	<p>Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$.</p> <p>This array contains the entries of the distributed vector $sub(x)$.</p>
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>a</i>	<p>(local) COMPLEX for <i>pcher</i> DOUBLE COMPLEX for <i>pzher</i></p> <p>Array, DIMENSION $(lld_a, LOCq(ja+n-1))$. This array contains the local pieces of the distributed matrix $sub(A)$. Before entry with <i>uplo</i> = 'U' or 'u', the n-by-n upper triangular part of the distributed matrix $sub(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $sub(A)$ is not referenced, and with <i>uplo</i> = 'L' or 'l', the n-by-n lower triangular part of the distributed matrix $sub(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $sub(A)$ is not referenced.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A .

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix $sub(A)$.
----------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------

With `uplo = 'L' or 'l'`, the lower triangular part of the array `a` is overwritten by the lower triangular part of the updated distributed matrix `sub(A)`.

p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

Syntax

```
call pcher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca )

call pzher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca )
```

Description

The `p?her2` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conj}(\text{sub}(y)') + \text{conj}(\alpha) * \text{sub}(y) * \text{conj}(\text{sub}(x)') + \text{sub}(A),$$

where:

`alpha` is a scalar,

`sub(A)` is a n -by- n distributed Hermitian matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx = m_x`, and $X(ix: ix+n-1, jx)$ if `incx = 1`,

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if `incy = m_y`, and $Y(iy: iy+n-1, jy)$ if `incy = 1`.

Input Parameters

`uplo` (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed Hermitian matrix `sub(A)` is used:
 If `uplo = 'U' or 'u'`, then the upper triangular part of the `sub(A)` is used.
 If `uplo = 'L' or 'l'`, then the low triangular part of the `sub(A)` is used.

<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code> Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code> Array, DIMENSION at least $(j_x-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code> Array, DIMENSION at least $(j_y-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for <code>pcher2</code> DOUBLE COMPLEX for <code>pzher2</code>

Array, `DIMENSION (lld_a, LOCq(ja+n-1))`. This array contains the local pieces of the distributed matrix `sub(A)`. Before entry with `uplo = 'U' or 'u'`, the n -by- n upper triangular part of the distributed matrix `sub(A)` must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of `sub(A)` is not referenced, and with `uplo = 'L' or 'l'`, the n -by- n lower triangular part of the distributed matrix `sub(A)` must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of `sub(A)` is not referenced.

ia, ja

(global) `INTEGER`. The row and column indices in the distributed matrix `A` indicating the first row and the first column of the submatrix `sub(A)`, respectively.

desca

(global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix `A`.

Output Parameters

a

With `uplo = 'U' or 'u'`, the upper triangular part of the array `a` is overwritten by the upper triangular part of the updated distributed matrix `sub(A)`.

With `uplo = 'L' or 'l'`, the lower triangular part of the array `a` is overwritten by the lower triangular part of the updated distributed matrix `sub(A)`.

p?symv

Computes a distributed matrix-vector product using a symmetric matrix.

Syntax

```
call pssymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)
```

```
call pdsymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)
```

Description

The `p?symv` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$$

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* symmetric distributed matrix, *sub(A)* = *A*(*ia:ia+n-1*, *ja:ja+n-1*),

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes *X*(*ix*, *jx:jx+n-1*) if *incx* = *m_x*, and *X*(*ix:ix+n-1*, *jx*) if *incx* = 1,

sub(y) denotes *Y*(*iy*, *jy:jy+n-1*) if *incy* = *m_y*, and *Y*(*iy:iy+n-1*, *jy*) if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) REAL for <code>pssymv</code> DOUBLE REAL for <code>pdsymv</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for <code>pssymv</code> DOUBLE REAL for <code>pdsymv</code> Array, DIMENSION (<i>lld_a</i> , <i>LOCq(ja+n-1)</i>). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry when <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain

	the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <code>sub(A)</code> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>beta</i>	(global) REAL for pssymv DOUBLE REAL for pdsymv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <code>sub(y)</code> need not be set on input.
<i>y</i>	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, DIMENSION at least $(j_y-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.

<i>descy</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) <code>INTEGER</code> . Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <code>sub(y)</code> .
----------	---------------------------------------------------------------------

p?syr

Performs a rank-1 update of a distributed symmetric matrix.

Syntax

```
call pssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca )
call pdsyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca )
```

Description

The `p?syr` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(x)' + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *n*-by-*n* distributed symmetric matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` is distributed vector.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,

Input Parameters

<i>uplo</i>	(global) <code>CHARACTER*1</code> . Specifies whether the upper or lower triangular part of the symmetric distributed matrix <code>sub(A)</code> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <code>sub(A)</code> is used.
-------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) REAL for <i>pssyr</i> DOUBLE REAL for <i>pdsyr</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) REAL for <i>pssyr</i> DOUBLE REAL for <i>pdsyr</i> Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>a</i>	(local) REAL for <i>pssyr</i> DOUBLE REAL for <i>pdsyr</i> Array, DIMENSION $(lld_a, LOCq(ja+n-1))$. This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.

<i>ia, ja</i>	(global) <code>INTEGER</code> . The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <code>A</code> .

Output Parameters

<i>a</i>	With <code>uplo = 'U' or 'u'</code> , the upper triangular part of the array <code>a</code> is overwritten by the upper triangular part of the updated distributed matrix <code>sub(A)</code> . With <code>uplo = 'L' or 'l'</code> , the lower triangular part of the array <code>a</code> is overwritten by the lower triangular part of the updated distributed matrix <code>sub(A)</code> .
----------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

p?syr2

Performs a rank-2 update of a distributed symmetric matrix.

Syntax

```
call pssyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca )

call pdsyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca )
```

Description

The `p?syr2` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \alpha * \text{sub}(y) * \text{sub}(x)' + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *n*-by-*n* distributed symmetric matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed symmetric matrix <code>sub(A)</code> is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <code>sub(A)</code> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <code>sub(A)</code> is used.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix <code>sub(A)</code>, $n \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for <code>pssyr2</code> DOUBLE REAL for <code>pdsyr2</code> Specifies the scalar <i>alpha</i>.</p>
<i>x</i>	<p>(local) REAL for <code>pssyr2</code> DOUBLE REAL for <code>pdsyr2</code> Array, DIMENSION at least $(j_x-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code>.</p>
<i>ix, jx</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <code>sub(x)</code>, respectively.</p>
<i>descx</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i>.</p>
<i>incx</i>	<p>(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code>. Only two values are supported, namely 1 and m_x. <i>incx</i> must not be zero.</p>
<i>y</i>	<p>(local) REAL for <code>pssyr2</code> DOUBLE REAL for <code>pdsyr2</code> Array, DIMENSION at least $(j_y-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code>.</p>

<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(Y)</i> . Only two values are supported, namely 1 and <i>m_Y.incy</i> must not be zero.
<i>a</i>	(local) REAL for pssyr2 DOUBLE REAL for pdsyr2 Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+n-1</i>)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix <i>sub(A)</i> . With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated distributed matrix <i>sub(A)</i> .
----------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

Syntax

```
call pstrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Description

The p?trmv routines perform one of the following distributed matrix-vector operations defined as

$\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$, or $\text{sub}(x) := \text{sub}(A)^T * \text{sub}(x)$, or $\text{sub}(x) := \text{conjg}(\text{sub}(A)^T) * \text{sub}(x)$,

where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix:ix+n-1, jx)$ if $incx = 1$,

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation: if <i>transa</i> = 'N' or 'n', then $\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$;

	<pre> if transa = 'T' or 't', then sub(x) :=sub (A) '*sub(x); if transa = 'C' or 'c', then sub(x) := conjg(sub(A)')*sub(x). </pre>
<i>diag</i>	<p>(global) CHARACTER*1. Specifies whether the matrix <code>sub(A)</code> is unit triangular:</p> <p>if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular;</p> <p>if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix <code>sub(A)</code>, $n \geq 0$.</p>
<i>a</i>	<p>(local) REAL for pstrmv DOUBLE PRECISION for pdtrmv COMPLEX for pctrmv DOUBLE COMPLEX for pztrmv Array, DIMENSION at least (<i>lld_a</i>, LOCq(1, <i>ja</i>+<i>n</i>-1)). Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix <code>sub(A)</code>, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix <code>sub(A)</code> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix <code>sub(A)</code>, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix <code>sub(A)</code> is not referenced. When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix <code>sub(A)</code> are not referenced either, but are assumed to be unity.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>x</i>	<p>(local) REAL for pstrmv DOUBLE PRECISION for pdtrmv COMPLEX for pctrmv DOUBLE COMPLEX for pztrmv</p>

	Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $sub(x)$, respectively.
$descx$	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
$incx$	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

x	Overwritten by the transformed distributed vector $sub(x)$.
-----	--------------------------------------------------------------

p?trsv

Solves a system of linear equations whose coefficients are in a distributed triangular matrix.

Syntax

```
call pstrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrvs(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Description

The p?trsv routines solve one of the systems of equations:

$sub(A)*sub(x) = b$, or $sub(A)'*sub(x) = b$, or $conjg(sub(A)')*sub(x) = b$,

where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$,

b and $\text{sub}(x)$ are n -element distributed vectors,

$\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m_x$, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$,.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) CHARACTER*1. Specifies the form of the system of equations: if <i>transa</i> = 'N' or 'n', then $\text{sub}(A) * \text{sub}(x) = b$; if <i>transa</i> = 'T' or 't', then $\text{sub}(A)' * \text{sub}(x) = b$; if <i>transa</i> = 'C' or 'c', then $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$.
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>a</i>	(local) REAL for pstrsv DOUBLE PRECISION for pdtrsv COMPLEX for pctrsv DOUBLE COMPLEX for pztrsv Array, DIMENSION at least $(\text{lld_a}, \text{LOCq}(1, \text{ja}+n-1))$. Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix *sub(A)* is not referenced. When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix *sub(A)* are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

desca

(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

x

(local) REAL for *pstrsv*

DOUBLE PRECISION for *pdtrsv*

COMPLEX for *pctrsv*

DOUBLE COMPLEX for *pztrsv*

Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$.

This array contains the entries of the distributed vector *sub(x)*. Before entry, *sub(x)* must contain the *n*-element right-hand side distributed vector *b*.

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix *x* indicating the first row and the first column of the submatrix *sub(x)*, respectively.

descx

(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *x*.

incx

(global) INTEGER. Specifies the increment for the elements of *sub(x)*. Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x

Overwritten with the solution vector.

PBLAS Level 3 Routines

PBLAS Level 3 routines perform distributed matrix-matrix operations. [Table 2-3](#) lists the PBLAS Level 3 routine groups and the data types associated with them.

Table 12-3 PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
p?gemm	s, d, c, z	Distributed matrix-matrix product of general matrices
p?hemm	c, z	Distributed matrix-matrix product, one matrix is Hermitian
p?herk	c, z	Rank-k update of a distributed Hermitian matrix
p?her2k	c, z	Rank-2k update of a distributed Hermitian matrix
p?symm	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
p?syrk	s, d, c, z	Rank-k update of a distributed symmetric matrix
p?syr2k	s, d, c, z	Rank-2k update of a distributed symmetric matrix
p?tran	s, d	Transposition of a real distributed matrix
p?tranc	c, z	Transposition of a complex distributed matrix (conjugated)
p?tranu	c, z	Transposition of a complex distributed matrix
p?trmm	s, d, c, z	Distributed matrix-matrix product, one matrix is triangular
p?trsm	s, d, c, z	Solution of a distributed matrix equation, one matrix is triangular

p?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.

Syntax

```
call psgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb,
descb, beta, c, ic, jc, descc)

call pdgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb,
descb, beta, c, ic, jc, descc)

call pcgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb,
descb, beta, c, ic, jc, descc)

call pzgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb,
descb, beta, c, ic, jc, descc)
```

Description

The p?gemm routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \beta * \text{sub}(C),$$

where:

op(x) is one of op(x) = x, or op(x) = x',

alpha and beta are scalars,

sub(A)=A(ia:ia+m-1, ja:ja+k-1), sub(B)=B(ib:ib+k-1, jb:jb+n-1), and
sub(C)=C(ic:ic+m-1, jc:jc+n-1), are distributed matrices.

Input Parameters

<i>transa</i>	(global) CHARACTER*1. Specifies the form of op(sub(A)) used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then op(sub(A)) = sub(A); if <i>transa</i> = 'T' or 't', then op(sub(A)) = sub(A)'; if <i>transa</i> = 'C' or 'c', then op(sub(A)) = sub(A)'.
<i>transb</i>	(global) CHARACTER*1. Specifies the form of op(sub(B)) used in the matrix multiplication:

	<p>if <i>transb</i> = 'N' or 'n', then $\text{op}(\text{sub}(B)) = \text{sub}(B)$;</p> <p>if <i>transb</i> = 'T' or 't', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$;</p> <p>if <i>transb</i> = 'C' or 'c', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$.</p>
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrices $\text{op}(\text{sub}(A))$ and $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrices $\text{op}(\text{sub}(B))$ and $\text{sub}(C)$, $n \geq 0$. The value of <i>n</i> must be at least zero.
<i>k</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{op}(\text{sub}(A))$ and the number of rows of the distributed matrix $\text{op}(\text{sub}(B))$. The value of <i>k</i> must be greater than or equal to 0.
<i>alpha</i>	(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar <i>alpha</i> . When <i>alpha</i> is equal to zero, then the local entries of the arrays <i>a</i> and <i>b</i> corresponding to the entries of the submatrices $\text{sub}(A)$ and $\text{sub}(B)$ respectively need not be set on input.
<i>a</i>	(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<i>lld_a</i> , <i>kla</i>), where <i>kla</i> is LOCc(<i>ja</i> + <i>k</i> -1) when <i>transa</i> = 'N' or 'n', and is LOCq(<i>ja</i> + <i>m</i> -1) otherwise. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local)REAL for psgemm DOUBLE PRECISION for pdgemm

	<p>COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<i>lld_b</i>, <i>klb</i>), where <i>klb</i> is LOCc(<i>jb+n-1</i>) when <i>transb</i> = 'N' or 'n', and is LOCq(<i>jb+k-1</i>) otherwise. Before entry this array must contain the local pieces of the distributed matrix <i>sub(B)</i>.</p>
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	<p>(global) REAL for psgermm DOUBLE PRECISION for pdgermm COMPLEX for pcgermm DOUBLE COMPLEX for pzgermm Specifies the scalar <i>beta</i>. When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.</p>
<i>c</i>	<p>(local)REAL for psgermm DOUBLE PRECISION for pdgermm COMPLEX for pcgermm DOUBLE COMPLEX for pzgermm Array, DIMENSION (<i>lld_a</i>, LOCq(<i>jc+n-1</i>)). Before entry this array must contain the local pieces of the distributed matrix <i>sub(C)</i>.</p>
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively
<i>descc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> distributed matrix $\alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \text{beta} * \text{sub}(C)$.
----------	----------------------------------------------------------------------------------------------------------------------------------------------------------------

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

```
call pchemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pzhemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

Description

The p?hemm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C),$

or

$\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C),$

where:

α and β are scalars,

$\text{sub}(A)$ is a Hermitian distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1)$, if $side = 'L'$, and $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, if $side = 'R'$.

$\text{sub}(B)$ and $\text{sub}(C)$ are m -by- n distributed matrices.

$\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$, $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$.

Input Parameters

side (global) CHARACTER*1. Specifies whether the Hermitian distributed matrix $\text{sub}(A)$ appears on the left or right in the operation:
if $side = 'L'$ or $'l'$, then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C);$
if $side = 'R'$ or $'r'$, then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C).$

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used:</p> <p>if $\text{uplo} = 'U'$ or $'u'$, then the upper triangular part is used;</p> <p>if $\text{uplo} = 'L'$ or $'l'$, then the lower triangular part is used.</p>
<i>m</i>	<p>(global) INTEGER. Specifies the number of rows of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the number of columns of the distribute submatrix $\text{sub}(C)$, $n \geq 0$.</p>
<i>alpha</i>	<p>(global) COMPLEX for pchemm DOUBLE COMPLEX for pzchemm Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) COMPLEX for pchemm DOUBLE COMPLEX for pzchemm Array, DIMENSION (lld_a, $\text{LOCq}(ja+na-1)$). Before entry this array must contain the local pieces of the symmetric distributed matrix $\text{sub}(A)$, such that when $\text{uplo} = 'U'$ or $'u'$, the na-by-na upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when $\text{uplo} = 'L'$ or $'l'$, the na-by-na lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A.</p>
<i>b</i>	<p>(local) COMPLEX for pchemm DOUBLE COMPLEX for pzchemm Array, DIMENSION (lld_b, $\text{LOCq}(jb+n-1)$). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$.</p>

<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>sub(C)</i> need not be set on input.
<i>c</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (<i>lld_c</i> , <i>LOCq(jc+n-1)</i>). Before entry this array must contain the local pieces of the distributed matrix <i>sub(C)</i> .
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively
<i>descc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> updated distributed matrix.
----------	-----------------------------------------------------------------------

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

```
call pchemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pzhemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

Description

The `p?hemm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

α and β are scalars,

$\text{sub}(A)$ is a Hermitian distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$, if $\text{side} = \text{'L'}$, and $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, if $\text{side} = \text{'R'}$.

$\text{sub}(B)$ and $\text{sub}(C)$ are m -by- n distributed matrices.

$$\text{sub}(B) = B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+n-1), \text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1).$$

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether the Hermitian distributed matrix $\text{sub}(A)$ appears on the left or right in the operation: if $\text{side} = \text{'L'}$ or 'l' , then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C)$; if $\text{side} = \text{'R'}$ or 'r' , then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C)$.
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used: if $\text{uplo} = \text{'U'}$ or 'u' , then the upper triangular part is used; if $\text{uplo} = \text{'L'}$ or 'l' , then the lower triangular part is used.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distribute submatrix $\text{sub}(C)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pchemm</code> DOUBLE COMPLEX for <code>pzhemm</code>

	Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+na-1</i>)). Before entry this array must contain the local pieces of the symmetric distributed matrix sub(<i>A</i>), such that when <i>uplo</i> = 'U' or 'u', the <i>na-by-na</i> upper triangular part of the distributed matrix sub(<i>A</i>) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(<i>A</i>) is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>na-by-na</i> lower triangular part of the distributed matrix sub(<i>A</i>) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(<i>A</i>) is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (<i>lld_b</i> , LOCq(<i>jb+n-1</i>)). Before entry this array must contain the local pieces of the distributed matrix sub(<i>B</i>).
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then sub(<i>C</i>) need not be set on input.
<i>c</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm

Array, `DIMENSION (lld_c, locq(jc+n-1))`. Before entry this array must contain the local pieces of the distributed matrix `sub(C)`.

`ic, jc` (global) `INTEGER`. The row and column indices in the distributed matrix `C` indicating the first row and the first column of the submatrix `sub(C)`, respectively

`desc` (global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix `C`.

Output Parameters

`C` Overwritten by the m -by- n updated distributed matrix.

p?herk

Performs a rank- k update of a distributed Hermitian matrix.

Syntax

```
call pcherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pzherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
```

Description

The `p?herk` routines perform a distributed matrix-matrix operation defined as

`sub(C) := alpha * sub(A) * conjg(sub(A)') + beta * sub(C)`,

or

`sub(C) := alpha * conjg(sub(A)') * sub(A) + beta * sub(C)`,

where:

`alpha` and `beta` are scalars,

`sub(C)` is an n -by- n Hermitian distributed matrix, `sub(C) = C(ic:ic+n-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A) = A(ia:ia+n-1, ja:ja+k-1)`, if `trans = 'N' or 'n'`, and `sub(A) = A(ia:ia+k-1, ja:ja+n-1)` otherwise.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <code>sub(C)</code> is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <code>sub(C)</code> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <code>sub(C)</code> is used.</p>
<i>trans</i>	<p>(global) CHARACTER*1. Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then <code>sub(C) := alpha*sub(A)*conjg(sub(A)') + beta*sub(C)</code>;</p> <p>if <i>trans</i> = 'C' or 'c', then <code>sub(C) := alpha*conjg(sub(A)')*sub(A) + beta*sub(C)</code>.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix <code>sub(C)</code>, $n \geq 0$.</p>
<i>k</i>	<p>(global) INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix <code>sub(A)</code>, and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrix <code>sub(A)</code>, $k \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for <code>pcherk</code> DOUBLE PRECISION for <code>pzherk</code> Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) COMPLEX for <code>pcherk</code> DOUBLE COMPLEX for <code>pzherk</code> Array, DIMENSION (<i>lld_a</i>, <i>kla</i>), where <i>kla</i> is <code>LOCq(ja+k-1)</code> when <i>trans</i> = 'N' or 'n', and is <code>LOCq(ja+n-1)</code> otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <code>sub(A)</code>.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>

<i>beta</i>	(global) REAL for pcherk DOUBLE PRECISION for pzherk Specifies the scalar <i>beta</i> .
<i>c</i>	(local) COMPLEX for pcherk DOUBLE COMPLEX for pzherk Array, DIMENSION (<i>lld_c</i> , LOCq(<i>jc+n-1</i>)). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>c</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>desc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>c</i> .

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix.
----------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

Syntax

FORTRAN 77:

```
call pcher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc,
descc)

call pzher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc,
descc)
```

Description

The p?her2k routines perform a distributed matrix-matrix operation defined as

$\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)') + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)') + \beta * \text{sub}(C),$

or

$\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)') * \text{sub}(A) + \beta * \text{sub}(C),$

where:

α and β are scalars,

$\text{sub}(C)$ is an n -by- n Hermitian distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$, if $trans = 'N'$ or $'n'$, and $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

$\text{sub}(B)$ is a distributed matrix, $\text{sub}(B) = B(ib:ib+n-1, jb:jb+k-1)$, if $trans = 'N'$ or $'n'$, and $\text{sub}(B) = B(ib:ib+k-1, jb:jb+n-1)$ otherwise.

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(C)$ is used:
 If *uplo* = 'U' or 'u', then the upper triangular part of the $\text{sub}(C)$ is used.
 If *uplo* = 'L' or 'l', then the low triangular part of the $\text{sub}(C)$ is used.

<i>trans</i>	<p>(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)) + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)) + \beta * \text{sub}(C)$; if <i>trans</i> = 'C' or 'c', then $\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)) * \text{sub}(A) + \beta * \text{sub}(C)$.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(C)$, $n \geq 0$.</p>
<i>k</i>	<p>(global) INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, and on entry with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, $k \geq 0$.</p>
<i>alpha</i>	<p>(global) COMPLEX for pcher2k DOUBLE COMPLEX for pzher2k Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) COMPLEX for pcher2k DOUBLE COMPLEX for pzher2k Array, DIMENSION (<i>lld_a</i>, <i>kla</i>), where <i>kla</i> is LOCq(<i>ja</i>+<i>k</i>-1) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>ja</i>+<i>n</i>-1) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix $\text{sub}(A)$.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>b</i>	<p>(local) COMPLEX for pcher2k DOUBLE COMPLEX for pzher2k Array, DIMENSION (<i>lld_b</i>, <i>klb</i>), where <i>klb</i> is LOCq(<i>jb</i>+<i>k</i>-1) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>jb</i>+<i>n</i>-1) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix $\text{sub}(B)$.</p>

<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) REAL for <i>pcher2k</i> DOUBLE PRECISION for <i>pzher2k</i> Specifies the scalar <i>beta</i> .
<i>c</i>	(local) COMPLEX for <i>pcher2k</i> DOUBLE COMPLEX for <i>pzher2k</i> Array, DIMENSION (<i>lld_c</i> , <i>LOCq(jc+n-1)</i>). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix.
----------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

p?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distributed matrices.

Syntax

FORTRAN 77:

```
call pssymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pdsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pcsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pzsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

Description

The p?s?ymm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

α and β are scalars,

$\text{sub}(A)$ is a symmetric distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1)$, if $side = 'L'$, and $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, if $side = 'R'$.

$\text{sub}(B)$ and $\text{sub}(C)$ are m -by- n distributed matrices.

$\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$, $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$.

Input Parameters

<i>side</i>	<p>(global) CHARACTER*1. Specifies whether the symmetric distributed matrix $\text{sub}(A)$ appears on the left or right in the operation:</p> <p>if <i>side</i> = 'L' or 'l', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C)$;</p> <p>if <i>side</i> = 'R' or 'r', then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C)$.</p>
<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used:</p> <p>if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used;</p> <p>if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.</p>
<i>m</i>	<p>(global) INTEGER. Specifies the number of rows of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the number of columns of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, DIMENSION (<i>lld_a</i>, LOCq(<i>ja+na-1</i>)). Before entry this array must contain the local pieces of the symmetric distributed matrix $\text{sub}(A)$, such that when <i>uplo</i> = 'U' or 'u', the <i>na</i>-by-<i>na</i> upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>na</i>-by-<i>na</i> lower triangular part of</p>

	the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A .
<i>b</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, DIMENSION (lld_b , $LOCq(jb+n-1)$). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix B .
<i>beta</i>	(global) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Specifies the scalar β . When β is set to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, DIMENSION (lld_c , $LOCq(jc+n-1)$). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(C)$.

<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>desc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>C</i>	Overwritten by the <i>m</i> -by- <i>n</i> updated matrix.
----------	-----------------------------------------------------------

p?syrk

Performs a rank-k update of a symmetric distributed matrix.

Syntax

```
call pssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc,
, desc)
call pdsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pcsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
)
call pzsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc,
, desc)
```

Description

The p?syrk routines perform a distributed matrix-matrix operation defined as

$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(A)^T + \beta * \text{sub}(C)$,

or

$\text{sub}(C) := \alpha * \text{sub}(A)^T * \text{sub}(A) + \beta * \text{sub}(C)$,

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* symmetric distributed matrix, $\text{sub}(C) = C(\text{ic}:\text{ic}+n-1, \text{jc}:\text{jc}+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+k-1)$, if *trans* = 'N' or 'n', and $\text{sub}(A) = A(\text{ia}:\text{ia}+k-1, \text{ja}:\text{ja}+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <code>sub(C)</code> is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <code>sub(C)</code> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <code>sub(C)</code> is used.</p>
<i>trans</i>	<p>(global) CHARACTER*1. Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then <code>sub(C) := alpha*sub(A)*sub(A)' + beta*sub(C)</code>;</p> <p>if <i>trans</i> = 'T' or 't', then <code>sub(C) := alpha*sub(A)'*sub(A) + beta*sub(C)</code>.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix <code>sub(C)</code>, $n \geq 0$.</p>
<i>k</i>	<p>(global) INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix <code>sub(A)</code>, and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the distributed matrix <code>sub(A)</code>, $k \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk Array, DIMENSION (<i>lld_a</i>, <i>kla</i>), where <i>kla</i> is LOCq(<i>ja</i>+<i>k</i>-1) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>ja</i>+<i>n</i>-1) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <code>sub(A)</code>.</p>

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk Specifies the scalar <i>beta</i> .
<i>c</i>	(local) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk Array, DIMENSION (<i>lld_c</i> , LOCq(<i>jc+n-1</i>)). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix.
----------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

p?syr2k

Performs a rank-2k update of a symmetric distributed matrix.

Syntax

```
call pssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pdsyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pcsyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pzsyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

Description

The p?syr2k routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B)^T + \alpha * \text{sub}(B) * \text{sub}(A)^T + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(A)^T * \text{sub}(B) + \alpha * \text{sub}(B)^T * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* symmetric distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$, if *trans* = 'N' or 'n', and $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

sub(B) is a distributed matrix, $\text{sub}(B) = B(ib:ib+n-1, jb:jb+k-1)$, if *trans* = 'N' or 'n', and $\text{sub}(B) = B(ib:ib+k-1, jb:jb+n-1)$ otherwise.

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix *sub(C)* is used:

	<p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.</p>
<i>trans</i>	<p>(global) CHARACTER*1. Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then <i>sub(C)</i> := <i>alpha</i>*<i>sub(A)</i>*<i>sub(B)</i> + <i>alpha</i>*<i>sub(B)</i>*<i>sub(A)</i> + <i>beta</i>*<i>sub(C)</i>;</p> <p>if <i>trans</i> = 'T' or 't', then <i>sub(C)</i> := <i>alpha</i>*<i>sub(B)</i>'*<i>sub(A)</i> + <i>alpha</i>*<i>sub(A)</i>'*<i>sub(B)</i> + <i>beta</i>*<i>sub(C)</i>.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix <i>sub(C)</i>, $n \geq 0$.</p>
<i>k</i>	<p>(global) INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrices <i>sub(A)</i> and <i>sub(B)</i>, and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the distributed matrices <i>sub(A)</i> and <i>sub(B)</i>, $k \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Array, DIMENSION (<i>lld_a</i>, <i>kla</i>), where <i>kla</i> is LOCq(<i>ja</i>+<i>k</i>-1) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>ja</i>+<i>n</i>-1) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(A)</i>.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i>, respectively.</p>

<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	<p>(local) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Array, DIMENSION (<i>lld_b</i>, <i>klb</i>), where <i>klb</i> is LOCq(<i>jb+k-1</i>) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>jb+n-1</i>) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(<i>B</i>).</p>
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	<p>(global) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>(local) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Array, DIMENSION (<i>lld_c</i>, LOCq(<i>jc+n-1</i>)). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i>-by-<i>n</i> upper triangular part of the symmetric distributed matrix sub(<i>C</i>) and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i>-by-<i>n</i> lower triangular part of the symmetric distributed matrix sub(<i>C</i>) and its strictly upper triangular part is not referenced.</p>
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix sub(<i>C</i>), respectively.

descc (global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

C With *uplo* = 'U' or 'u', the upper triangular part of `sub(C)` is overwritten by the upper triangular part of the updated distributed matrix.
 With *uplo* = 'L' or 'l', the lower triangular part of `sub(C)` is overwritten by the upper triangular part of the updated distributed matrix.

p?tran

Transposes a real distributed matrix.

Syntax

```
call pstran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdtran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Description

The `p?tran` routines transpose a real distributed matrix. The operation is defined as

`sub(C) := beta * sub(C) + alpha * sub(A)'`,

where:

alpha and *beta* are scalars,

`sub(C)` is an *m*-by-*n* distributed matrix, `sub(C) = C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A) = A(ia:ia+n-1, ja:ja+m-1)`.

Input Parameters

m (global) `INTEGER`. Specifies the number of rows of the distributed matrix `sub(C)`, $m \geq 0$.

n (global) `INTEGER`. Specifies the number of columns of the distributed matrix `sub(C)`, $n \geq 0$.

alpha (global) `REAL` for `pstran`

	DOUBLE PRECISION for <code>pdtran</code> Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) REAL for <code>pstran</code> DOUBLE PRECISION for <code>pdtran</code> Array, DIMENSION (<code>lld_a</code> , <code>LOCq(ja+m-1)</code>). This array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <code>A</code> .
<code>beta</code>	(global) REAL for <code>pstran</code> DOUBLE PRECISION for <code>pdtran</code> Specifies the scalar <code>beta</code> . When <code>beta</code> is equal to zero, then <code>sub(C)</code> need not be set on input.
<code>c</code>	(local) REAL for <code>pstran</code> DOUBLE PRECISION for <code>pdtran</code> Array, DIMENSION (<code>lld_c</code> , <code>LOCq(jc+n-1)</code>). This array contains the local pieces of the distributed matrix <code>sub(C)</code> .
<code>ic, jc</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>C</code> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.
<code>desc</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <code>C</code> .

Output Parameters

<code>c</code>	Overwritten by the updated submatrix.
----------------	---------------------------------------

p?tranu

Transposes a distributed complex matrix.

Syntax

```
call pctranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

```
call pztranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Description

The p?tranu routines transpose a complex distributed matrix. The operation is defined as

$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)'$,

where:

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub(C)</i> , $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub(C)</i> , $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pctranu DOUBLE COMPLEX for pztranu Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pctranu DOUBLE COMPLEX for pztranu Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+m-1</i>)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .

<i>beta</i>	(global) COMPLEX for <code>pctransu</code> DOUBLE COMPLEX for <code>pztransu</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <code>sub(C)</code> need not be set on input.
<i>c</i>	(local) COMPLEX for <code>pctransu</code> DOUBLE COMPLEX for <code>pztransu</code> Array, DIMENSION (<code>lld_c</code> , <code>LOCq(jc+n-1)</code>). This array contains the local pieces of the distributed matrix <code>sub(C)</code> .
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>c</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.
<i>desc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>c</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?tranc

Transposes a complex distributed matrix, conjugated.

Syntax

```
call pctranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pztranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
```

Description

The `p?tranc` routines transpose a complex distributed matrix. The operation is defined as
 $\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{conjg}(\text{sub}(A)'),$

where:

alpha and *beta* are scalars,

`sub(C)` is an *m*-by-*n* distributed matrix, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>petranc</code> DOUBLE COMPLEX for <code>pztranc</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for <code>petranc</code> DOUBLE COMPLEX for <code>pztranc</code> Array, DIMENSION (<i>lld_a</i> , <i>LOCq(ja+m-1)</i>). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) COMPLEX for <code>petranc</code> DOUBLE COMPLEX for <code>pztranc</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) COMPLEX for <code>petranc</code> DOUBLE COMPLEX for <code>pztranc</code> Array, DIMENSION (<i>lld_c</i> , <i>LOCq(jc+n-1)</i>). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

c

Overwritten by the updated submatrix.

p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

Syntax

```
call pstrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
jb, descb)

call pdtrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
jb, descb)

call pctrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
jb, descb)

call pztrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
jb, descb)
```

Description

The p?trmm routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

$$\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$$

or

$$\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$$

where:

α is a scalar,

$\text{sub}(B)$ is an m -by- n distributed matrix, $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$.

A is a unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1)$, if $side = 'L'$ or $'l'$, and $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, if $side = 'R'$ or $'r'$.

$\text{op}(\text{sub}(A))$ is one of $\text{op}(\text{sub}(A)) = \text{sub}(A)$, or $\text{op}(\text{sub}(A)) = \text{sub}(A)'$, or $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$.

Input Parameters

<i>side</i>	<p>(global) CHARACTER*1. Specifies whether $\text{op}(\text{sub}(A))$ appears on the left or right of $\text{sub}(B)$ in the operation:</p> <p>if <i>side</i> = 'L' or 'l', then $\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$;</p> <p>if <i>side</i> = 'R' or 'r', then $\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$.</p>
<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular:</p> <p>if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular;</p> <p>if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.</p>
<i>transa</i>	<p>(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication:</p> <p>if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$;</p> <p>if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)^T$;</p> <p>if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A))$.</p>
<i>diag</i>	<p>(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular:</p> <p>if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular;</p> <p>if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.</p>
<i>m</i>	<p>(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(B)$, $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(B)$, $n \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for pstrmm DOUBLE PRECISION for pdtrmm COMPLEX for pctrmm DOUBLE COMPLEX for pztrmm Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then the array <i>b</i> need not be set before entry.</p>
<i>a</i>	<p>(local) REAL for pstrmm DOUBLE PRECISION for pdtrmm COMPLEX for pctrmm</p>

DOUBLE COMPLEX for pztrmm

Array, DIMENSION (lld_a, ka), where ka is at least $LOCq(1, ja+m-1)$ when $side = 'L'$ or $'l'$ and is at least $LOCq(1, ja+n-1)$ when $side = 'R'$ or $'r'$.

Before entry with $uplo = 'U'$ or $'u'$, this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $sub(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $sub(A)$ is not referenced.

Before entry with $uplo = 'L'$ or $'l'$, this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $sub(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $sub(A)$ is not referenced.

When $diag = 'U'$ or $'u'$, the local entries corresponding to the diagonal elements of the submatrix $sub(A)$ are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.

$desca$

(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A .

b

(local) REAL for pstrmm

DOUBLE PRECISION for pdtrmm

COMPLEX for pctrmm

DOUBLE COMPLEX for pztrmm

Array, DIMENSION ($lld_b, LOCq(1, jb+n-1)$).

Before entry, this array contains the local pieces of the distributed matrix $sub(B)$.

ib, jb

(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $sub(B)$, respectively.

$descb$

(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix B .

Output Parameters

b

Overwritten by the transformed distributed matrix.

p?trsm

Solves a distributed matrix equation (one matrix operand is triangular).

Syntax

```
call pstrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)

call pdtrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)

call pctrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)

call pztrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

Description

The p?trsm routines solve one of the following distributed matrix equations:

$\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B),$

or

$X * \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B),$

where:

α is a scalar,

X and $\text{sub}(B)$ are m -by- n distributed matrices, $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1);$

A is a unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1),$ if $side = 'L'$ or $'l',$ and $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1),$ if $side = 'R'$ or $'r';$

$\text{op}(\text{sub}(A))$ is one of $\text{op}(\text{sub}(A)) = \text{sub}(A),$ or $\text{op}(\text{sub}(A)) = \text{sub}(A)',$ or $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)').$

The distributed matrix $\text{sub}(B)$ is overwritten by the solution matrix $X.$

Input Parameters

side (global) CHARACTER*1. Specifies whether $\text{op}(\text{sub}(A))$ appears on the left or right of X in the equation:

	<p>if <i>side</i> = 'L' or 'l', then $\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B)$;</p> <p>if <i>side</i> = 'R' or 'r', then $X * \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B)$.</p>
<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the distributed matrix <i>sub(A)</i> is upper or lower triangular:</p> <p>if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular;</p> <p>if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.</p>
<i>transa</i>	<p>(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation:</p> <p>if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$;</p> <p>if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)^T$;</p> <p>if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)^T)$.</p>
<i>diag</i>	<p>(global) CHARACTER*1. Specifies whether the matrix <i>sub(A)</i> is unit triangular:</p> <p>if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular;</p> <p>if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.</p>
<i>m</i>	<p>(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub(B)</i>, $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub(B)</i>, $n \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pctrsm DOUBLE COMPLEX for pztrsm Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.</p>
<i>a</i>	<p>(local) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pctrsm DOUBLE COMPLEX for pztrsm Array, DIMENSION (<i>lld_a</i>, <i>ka</i>), where <i>ka</i> is at least $\text{LOCq}(1, ja+m-1)$ when <i>side</i> = 'L' or 'l' and is at least $\text{LOCq}(1, ja+n-1)$ when <i>side</i> = 'R' or 'r'.</p>

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix *sub(A)* is not referenced. Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix *sub(A)* is not referenced. When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix *sub(A)* are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

desca

(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b

(local) REAL for *pstrsm*
DOUBLE PRECISION for *pdtrsm*
COMPLEX for *pctrsm*
DOUBLE COMPLEX for *pztrsm*

Array, DIMENSION (*lld_b*, LOCq(1, *jb+n-1*)).

Before entry, this array contains the local pieces of the distributed matrix *sub(B)*.

ib, jb

(global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix *sub(B)*, respectively.

descb

(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

Output Parameters

b

Overwritten by the solution distributed matrix *x*.

Partial Differential Equations Support

13

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Library (see [Poisson Library Routines](#)).

Poisson Library is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the one that the Poisson Library provides. As it may be hard enough to modify the original code so as to make it work with Poisson Library, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Library routines can be called from C and Fortran 90, although the interfaces description uses C convention. Fortran 90 users can find routine calls specifics in the “[Calling PDE Support Routines from Fortran 90](#)” section.

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter “[Fast Fourier Transforms](#)”, Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this manual, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

To describe the Intel MKL TT interface, the C convention is used. Fortran users should refer to [Calling PDE Support Routines from Fortran 90](#).

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to the “[FFTW to Intel® MKL Wrappers for FFTW 3.x](#)” section in [Appendix G](#) for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason

why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, k = 1, \dots, n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, i = 1, \dots, n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, k = 1, \dots, n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, i = 1, \dots, n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad k = 1, \dots, n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad i = 1, \dots, n$$

Forward cosine transform

$$F(k) = \frac{1}{n} \left[f(0) + f(n) \cos k\pi \right] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, \quad k = 0, \dots, n$$

Backward cosine transform

$$f(i) = \frac{1}{2} \left[F(0) + F(n) \cos i\pi \right] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, \quad i = 0, \dots, n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, \quad k = 0, \dots, n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, i = 0, \dots, n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

NOTE. The size of the transform n can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table 13-1](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

Table 13-1 TT Interface Routines

Routine	Description
<code>?_init_trig_transform</code>	Initializes basic data structures of Trigonometric Transforms.
<code>?_commit_trig_transform</code>	Checks consistency and correctness of user-defined data as well as creates a data structure to be used by Intel MKL FFT interface ¹ .
<code>?_forward_trig_transform</code> <code>?_backward_trig_transform</code>	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
<code>free_trig_transform</code>	Cleans the memory used by a data structure needed for calling FFT interface ¹ .

¹TT routines call Intel MKL FFT interface for better performance.

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in [Table 13-1](#).

NOTE. Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure 13-1](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

Figure 13-1 Typical Order of Invoking TT Interface Routines

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```

...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f ! If you want to preserve the data
stored in f,
save them before this place in your code */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...

```

You can find examples of Fortran 90 and C code that use TT interface routines to solve one-dimensional Helmholtz problem in the “[Trigonometric Transform Code Examples](#)” section in Appendix C.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the “[Trigonometric Transform Code Examples](#)” section in Appendix C).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING. To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

NOTE. If you need a copy of your input data arrays, save them yourself.

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section “[FFT Functions](#)” in chapter “Fast Fourier Transforms”), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform (int *n, int *tt_type, int ipar[], double dpar[],
int *stat);
```

```
void s_init_trig_transform (int *n, int *tt_type, int ipar[], float spar[],
int *stat);
```

Input Parameters

<i>n</i>	int*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size $n+1$ for all but staggered2 transforms. Staggered2 transforms require the vector of size n .
<i>tt_type</i>	int*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

Output Parameters

<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
-------------	-----------------------------------------------------------------------------------------------

<code>dpar</code>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<code>spar</code>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.
<code>stat</code>	int*. Contains the routine completion status, which is also written to <code>ipar[6]</code> . The status should be 0 to proceed to other TT routines.

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of `ipar` and `dpar` (`spar`) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array `ipar`. In the `dpar` or `spar` array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. You can skip calling the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

Return Values

<code>stat= 0</code>	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <code>stat</code> value.
<code>stat= -99999</code>	The routine failed to complete the task.

?_commit_trig_transform

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);

void s_commit_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle, int
ipar[], float spar[], int *stat);
```

Input Parameters

<i>f</i>	<p>double for <code>d_commit_trig_transform</code>, float for <code>s_commit_trig_transform</code>, array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:</p> <ul style="list-style-type: none"> • $f[0]$ and $f[n]$ for sine transforms • $f[n]$ for staggered cosine transforms • $f[0]$ for staggered sine transforms. <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.</p>
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>dpar</i>	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.

<i>spar</i>	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine performs only a basic check for correctness and consistency of the parameters. If you are going to modify parameters of TT routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_trig_transform`, the `?_commit_trig_transform` routine is mandatory, and you cannot skip calling it in your code.

Return Values

stat= 11

The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.

stat= 10

The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.

`stat= 1`

The routine produced some warnings. You may proceed with computations by assigning `ipar[6]=0` if you are sure that the parameters are correct.

`stat= 0`

The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in `ipar`, `dpar` or `spar` parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

NOTE. Although positive values of `stat` usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve `stat=0`.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);
```

```
void s_forward_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], float spar[], int *stat);
```

Input Parameters

`f` double for `d_forward_trig_transform`,
 float for `s_forward_trig_transform`,

array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- $f[0]$ and $f[n]$ for sine transforms
- $f[n]$ for staggered cosine transforms
- $f[0]$ for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the [Poisson Library Routines](#) section), which the TT interface is primarily designed for.

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”).
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem n , which

determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

NOTE. If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_forward_trig_transform` routine.

Return Values

stat = 0

The routine completed the task normally.

stat = -100

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.

stat = -1000

The routine stopped because of an FFT interface error.

stat = -10000

The routine stopped because its commit step failed to complete or the parameter *ipar*[0] was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);
```

```
void s_backward_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], float spar[], int *stat);
```

Input Parameters

<i>f</i>	<p>double for <code>d_backward_trig_transform</code>, float for <code>s_backward_trig_transform</code>, array of size n for <code>staggered2</code> transforms and of size $n+1$ for all other transforms, where n is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:</p> <ul style="list-style-type: none"> • $f[0]$ and $f[n]$ for sine transforms • $f[n]$ for staggered cosine transforms • $f[0]$ for staggered sine transforms. <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.</p>
<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine computes the backward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_backward_trig_transform` with the `ipar` array. The size of the problem n , which determines sizes of the array parameters, is also passed to the routine with the `ipar` array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in `dpar` or `spar`. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector f with the transformed vector.

NOTE. If you need a copy of the data vector f to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

Return Values

`stat= 0`

The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in `ipar`, `dpar` or `spar` parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because its commit step failed to complete or the parameter `ipar[0]` was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform (DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], int *stat);
```

Input Parameters

<i>ipar</i>	<code>int</code> array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>handle</i>	<code>DFTI_DESCRIPTOR_HANDLE*</code> . The data structure used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”).

Output Parameters

<i>handle</i>	The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	<code>int*</code> . Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine cleans the memory used by the *handle* structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -99999	The routine failed to complete the task.

Common Parameters

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE. Initial values are assigned to the array parameters by the appropriate `?_init_trig_transform` and `?_commit_trig_transform` routines.

ipar `int` array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in [Table 13-2](#):

Table 13-2 Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The <code>?_init_trig_transform</code> routine sets <code>ipar[0]=n</code> , and all subsequently called TT routines use <code>ipar[0]</code> as the size of the transform.
1	Contains error messaging options: <ul style="list-style-type: none"> <code>ipar[1]=-1</code> indicates that all error messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. <code>ipar[1]=0</code> indicates that no error messages will be printed. <code>ipar[1]=1</code> (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen). <p>In case of errors, each TT routine assigns a non-zero value to <code>stat</code> regardless of the <code>ipar[1]</code> setting.</p>
2	Contains warning messaging options: <ul style="list-style-type: none"> <code>ipar[2]=-1</code> indicates that all warning messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. <code>ipar[2]=0</code> indicates that no warning messages will be printed.

Index	Description
	<ul style="list-style-type: none"> <code>ipar[2]=1</code> (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen). <p>In case of warnings, the <code>stat</code> parameter will acquire a non-zero value regardless of the <code>ipar[2]</code> setting.</p>
3 through 4	Reserved for future use.
5	Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <code>ipar[5]=tt_type</code> , and all subsequently called TT routines use <code>ipar[5]</code> as the type of the transform.
6	Contains the <code>stat</code> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <code>stat=0</code> .
7	<p>Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <code>dpar</code> (<code>spar</code>) and <code>handle</code>. <code>ipar[7]=0</code> indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1.</p> <p>The possibility to check correctness and consistency of input data without initializing data structures <code>dpar</code>, <code>spar</code> and <code>handle</code> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <code>ipar[7]</code> gives only if you are sure to have supplied proper tolerance value in the <code>dpar</code> or <code>spar</code> array. Otherwise, avoid tuning this parameter.</p>
8	<p>Contains message style options for TT routines. If <code>ipar[8]=0</code> then TT routines print all error and warning messages in Fortran-style notations. Otherwise, TT routines print the messages in C-style notations. The default value is 1.</p> <p>When selecting between these notations, mind that by default, numbering of elements in C arrays starts from 0 and in Fortran, it starts from 1. For example, for a C-style message "<i>parameter ipar[0]=3 should be an even integer</i>", the corresponding Fortran-style message will be "<i>parameter ipar(1)=3 should be an even integer</i>". The use of <code>ipar[8]</code> enables you to view messages in a more convenient style.</p>

Index	Description
9	Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Poisson Library. The default value is 1. You are highly recommended not to alter this value. See also Caveat on Parameter Modifications .
10	Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in the "FFTW to Intel® MKL Wrappers for FFTW 3.x" section in Appendix G . See also Caveat on Parameter Modifications .
11 through 127	Reserved for future use.

NOTE. You may declare the *ipar* array in your code as `int ipar[11]`. However, for compatibility with later versions of Intel MKL TT interface, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	double array of size $5n/2+2$, holds data needed for double-precision routines to perform TT computations. This array is initialized in the d_init_trig_transform and d_commit_trig_transform routines.
<i>spar</i>	float array of size $5n/2+2$, holds data needed for single-precision routines to perform TT computations. This array is initialized in the s_init_trig_transform and s_commit_trig_transform routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in [Table 13-3](#):

Table 13-3 Elements of the *dpar* and *spar* Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate ?_commit_trig_transform routine. For a staggered cosine or a sine transform, $f[n]$ should be equal to 0.0 and for a staggered sine or a sine transform, $f[0]$ should be equal to 0.0. The ?_commit_trig_transform routine checks whether absolute values of these parameters are below $dpar[0]*n$

Index	Description
	or $spar[0]*n$, depending on the routine precision. To suppress warnings resulting from tolerance checks, set $dpar[0]$ or $spar[0]$ to a sufficiently large number.
1	Reserved for future use.
2 through $5n/2+1$	<p>Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform tt_type, set up in the <code>?_commit_trig_transform</code> routine:</p> <ul style="list-style-type: none"> • If $tt_type=MKL_SINE_TRANSFORM$, the transform uses only the first $n/2$ array elements, which contain tabulated sine values. • If $tt_type=MKL_STAGGERED_SINE_TRANSFORM$, the transform uses only the first $3n/2$ array elements, which contain tabulated sine and cosine values. • If $tt_type=MKL_STAGGERED2_SINE_TRANSFORM$, the transform uses all the $5n/2$ array elements, which contain tabulated sine and cosine values. • If $tt_type=MKL_COSINE_TRANSFORM$, the transform uses only the first n array elements, which contain tabulated cosine values. • If $tt_type=MKL_STAGGERED_COSINE_TRANSFORM$, the transform uses only the first $3n/2$ elements, which contain tabulated sine and cosine values. • If $tt_type=MKL_STAGGERED2_COSINE_TRANSFORM$, the transform uses all the $5n/2$ elements, which contain tabulated sine and cosine values.

NOTE. To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip calling the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE. To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING. The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the TT language-specific header files to include in their code. Currently, the following of them are available:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_trig_transforms.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE. Use of the Intel MKL TT software without including one of the above header files is not supported.

C-specific Header File

The C-specific header file defines the following function prototypes:

```
void d_init_trig_transform(int *, int *, int *, double *, int *);
```

```
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
```

```
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);

void s_init_trig_transform(int *, int *, int *, float *, int *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, int *, int *);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes:

```
SUBROUTINE D_INIT_TRIG_TRANSFORM(n, tt_type, ipar, dpar, stat)
```

```
    INTEGER, INTENT(IN) :: n, tt_type
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
```

```
    REAL(8), INTENT(INOUT) :: dpar(*)
```

```
    INTEGER, INTENT(OUT) :: stat
```

```
END SUBROUTINE D_INIT_TRIG_TRANSFORM
```

```
SUBROUTINE D_COMMIT_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
```

```
    REAL(8), INTENT(INOUT) :: f(*)
```

```
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
```

```
    REAL(8), INTENT(INOUT) :: dpar(*)
```

```
    INTEGER, INTENT(OUT) :: stat
```

```
END SUBROUTINE D_COMMIT_TRIG_TRANSFORM
```

```
SUBROUTINE D_FORWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
```

```
    REAL(8), INTENT(INOUT) :: f(*)
```

```
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
```

```
    REAL(8), INTENT(INOUT) :: dpar(*)
```

```
    INTEGER, INTENT(OUT) :: stat
```

```
END SUBROUTINE D_FORWARD_TRIG_TRANSFORM
```

```
SUBROUTINE D_BACKWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
```

```
    REAL(8), INTENT(INOUT) :: f(*)
```

```
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_BACKWARD_TRIG_TRANSFORM

SUBROUTINE S_INIT_TRIG_TRANSFORM(n, tt_type, ipar, spar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_INIT_TRIG_TRANSFORM

SUBROUTINE S_COMMIT_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_COMMIT_TRIG_TRANSFORM

SUBROUTINE S_FORWARD_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_FORWARD_TRIG_TRANSFORM
```

```

SUBROUTINE S_BACKWARD_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_BACKWARD_TRIG_TRANSFORM

```

```

SUBROUTINE FREE_TRIG_TRANSFORM(handle, ipar, stat)
    INTEGER, INTENT(INOUT) :: ipar(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE FREE_TRIG_TRANSFORM

```

Fortran 90 specifics of the TT routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Poisson Library Routines

In addition to Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel® MKL supports the Poisson Library interface, referred to as PL interface. The interface implements a group of routines (PL routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems being solved are defined more exactly in the [Poisson Library Implemented](#) subsection. The PL interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The interface can adjust style of error and warning messages to C or Fortran notations by setting up a dedicated parameter. This adds convenience to debugging, because users can read information in the way that is natural for their code. The Intel MKL PL interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

To describe the Intel MKL PL interface, the C convention is used. Fortran usage specifics can be found in the [Calling PDE Support Routines from Fortran 90](#) section.

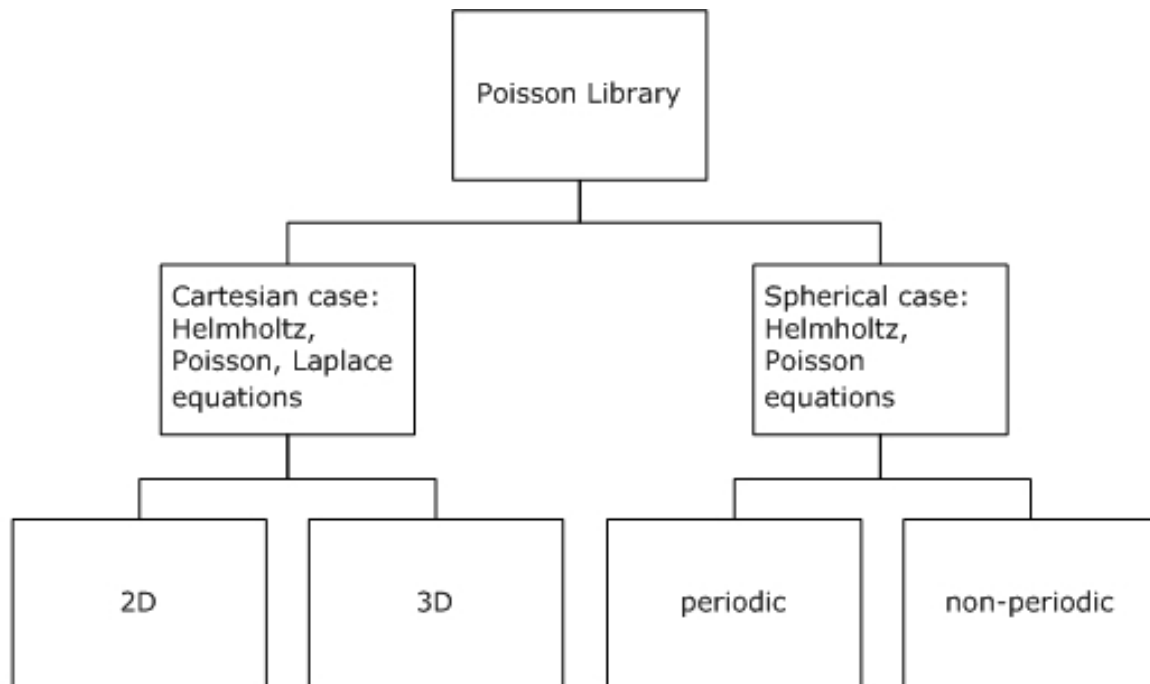

NOTE. Fortran users should mind that respective array indices in Fortran increase by 1.

Poisson Library Implemented

PL routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure 13-2](#) shows the general structure of the Poisson Library.

Figure 13-2 Structure of the Poisson Library

Sections below provide details of the problems that can be solved using Intel MKL PL.

Two-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$ on a Cartesian plane:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y\}, bd_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y\}, bd_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The wildcard "+" may stand for any of the symbols a_x , b_x , a_y , b_y , so that bd_+ denotes any of the above boundaries.

The PL interface description uses the following notation for boundaries of a rectangular domain $a_\phi < \phi < b_\phi$, $a_\theta < \theta < b_\theta$ on a sphere $0 \leq \phi \leq 2\pi$, $0 \leq \theta \leq \pi$:

$$bd_a_\phi = \{\phi = a_\phi, a_\theta \leq \theta \leq b_\theta\}, bd_b_\phi = \{\phi = b_\phi, a_\theta \leq \theta \leq b_\theta\}$$

$$bd_a_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = a_\theta\}, bd_b_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols a_ϕ , b_ϕ , a_θ , b_θ , so that $bd_~$ denotes any of the above boundaries.

Two-dimensional (2D) Helmholtz problem on a Cartesian plane

The 2D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), q = \text{const} \geq 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$$n = -x \text{ on } bd_a_x, \quad n = x \text{ on } bd_b_x,$$

$$n = -y \text{ on } bd_a_y, \quad n = y \text{ on } bd_b_y.$$

Two-dimensional (2D) Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y)=0$. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ .

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, \quad q = const \geq 0,$$
$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle that is, a domain bounded by angles $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$, with boundary conditions for particular domains listed in [Table 13-4](#).

Table 13-4 Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\phi - a_\phi < 2 \pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary $bd_~$	<i>non-periodic</i>
Where $a_\phi = 0, b_\phi = 2 \pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries bd_a_θ and bd_b_θ	<i>periodic</i>
Entire sphere, that is, $a_\phi = 0, b_\phi = 2 \pi, a_\theta = 0$, and $b_\theta = \pi$	Boundary condition $\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\substack{\theta \rightarrow 0 \\ \theta \rightarrow \pi}} = 0$	<i>periodic</i>
at the poles.		

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$ in cases listed in [Table 13-4](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, a uniform mesh is built in the rectangular domain:

$$\left\{ x_i = a_x + ih_x, y_j = a_y + jh_y \right\},$$

$$i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

in the Cartesian case and

$$\left\{ \phi_i = a_\phi + ih_\phi, \theta_j = a_\theta + jh_\theta \right\},$$

$$i = 0, \dots, n_\phi, j = 0, \dots, n_\theta, h_\phi = \frac{b_\phi - a_\phi}{n_\phi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}$$

in the spherical case.

Poisson Library uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i, y_j) provided that the user knows the values of the right-hand side $f(x, y)$ in these points and the values of the appropriate boundary functions $G(x, y)$ and/or $g(x, y)$ in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (ϕ_i, θ_j) provided that the user knows the values of the right-hand side $f(\phi, \theta)$ in these points.

NOTE. The number of mesh intervals n_ϕ in the ϕ direction of a spherical mesh must be even in the periodic case. The current implementation of the Poisson Library does not support meshes with the number of intervals that does not meet this condition.

Three-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, bd_b_x = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, bd_b_y = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\}$$

$$bd_a_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}, bd_b_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}.$$

The wildcard "+" may stand for any of the symbols $a_x, b_x, a_y, b_y, a_z, b_z$, so that bd_+ denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), q = \text{const} \geq 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y, z) = G(x, y, z)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd_{-a_x}, n = x \text{ on } bd_{b_x},$$

$$n = -y \text{ on } bd_{-a_y}, n = y \text{ on } bd_{b_y},$$

$$n = -z \text{ on } bd_{-a_z}, n = z \text{ on } bd_{b_z}.$$

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with Dirichlet or Neumann boundary condition on each boundary bd_+ .

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y, z)=0$. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ .

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh is built in the parallelepiped domain

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\}$$

where

$$i = 0, \dots, n_x, j = 0, \dots, n_y, k = 0, \dots, n_z$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}$$

The Poisson Library uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k) , provided that the user knows the values of the right-hand side $f(x, y, z)$ in these points and the values of the appropriate boundary functions $G(x, y, z)$ and/or $g(x, y, z)$ in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking PL Routines

NOTE. This description always considers the solution process for the Helmholtz problem, because Fast Poisson Solver and Fast Laplace Solver are special cases of Fast Helmholtz Solver (see [Poisson Library Implemented](#)).

Computation of a solution of the Helmholtz problem using the PL interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table 13-5](#) lists the routines and briefly describes their purpose.

Most PL routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with “s” and “d”. The wildcard “?” stands for either of these symbols in routine names. The routines for Cartesian coordinate system have 2D and 3D versions. Their names end respectively in “2D” and “3D”. The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in “p” and “np”

Table 13-5 PL Interface Routines

Routine	Description
<code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/ ?_init_sph_p/?_init_sph_np</code>	Initializes basic data structures of Poisson Library for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
<code>?_commit_Helmholtz_2D/?_com- mit_Helmholtz_3D/ ?_commit_sph_p/?_com- mit_sph_np</code>	Checks consistency and correctness of user's data, creates and initializes data structures to be used by the Intel MKL FFT interface ¹ , as well as other data structures needed for the solver.

Routine	Description
<code>?_Helmholtz_2D/?_Helmholtz_3D/ ?_sph_p/?_sph_np</code>	Computes an approximate solution of 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Library Implemented) specified by the parameters.
<code>free_Helmholtz_2D/free_Helmholtz_3D/ free_sph_p/free_sph_np</code>	Cleans the memory used by the data structures needed for calling the Intel MKL FFT interface ¹ .

¹ PL routines call the Intel MKL FFT interface for better performance.

To find an approximate solution of Helmholtz problem only once, the Intel MKL PL interface routines are normally invoked in the order in which they are listed in [Table 13-5](#).

NOTE. Though the order of invoking PL routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure 13-3](#) indicates the typical order in which PL routines can be invoked in a general case.

Figure 13-3 Typical Order of Invoking PL Routines

A general scheme of using PL routines for double-precision computations in a 3D Cartesian case is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a 2D Cartesian case differs from the one below in the set of routine parameters and the ending of routine names: "2D" instead of "3D".

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, BCtype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to keep the
data stored in f,
save it before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar,
dpar, &stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

A general scheme of using PL routines for double-precision computations in a spherical periodic case is shown below. Similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a spherical non-periodic case differs from the one below in the set of routine parameters and the ending of routine names: "np" instead of "p".

```
...
d_init_sph_p(&ap, &bp, &at, &bt, &np, &nt, &q, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to
keep the data stored in f, save it before the function call below */
d_commit_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
d_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
free_sph_p(&handle_s, &handle_c, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

You can find examples of Fortran 90 and C code that use PL routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the “[Poisson Library Code Examples](#)” section in Appendix C.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the “[Poisson Library Code Examples](#)” section in Appendix C).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All PL routines use parameters for passing various options to the routines. These parameters are arrays *ipar*, *dpar* and *spar*. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING. To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

PL routines take arrays of user data as input. For example, user arrays are passed to the routine `d_Helmholtz_3D` to compute an approximate solution to 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL PL routines do not make copies of user input arrays.

NOTE. If you need a copy of your input data arrays, save them yourself.

PL Routines for the Cartesian Solver

The section gives detailed description of Cartesian PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, 2D and 3D, are described together.

NOTE. Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

PL routines call the Intel MKL FFT interface (described in section “[FFT Functions](#)” in chapter “Fast Fourier Transforms”), which enhances performance of the routines.

?_init_Helmholtz_2D/?_init_Helmholtz_3D

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```
void d_init_Helmholtz_2D(double* ax, double* bx, double* ay, double* by,
int* nx, int* ny, char* Bctype, double* q, int* ipar, double* dpar, int*
stat);

void s_init_Helmholtz_2D(float* ax, float* bx, float* ay, float* by, int*
nx, int* ny, char* Bctype, float* q, int* ipar, float* spar, int* stat);

void d_init_Helmholtz_3D(double* ax, double* bx, double* ay, double* by,
double* az, double* bz, int* nx, int* ny, int* nz, char* Bctype, double* q,
int* ipar, double* dpar, int* stat);

void s_init_Helmholtz_3D(float* ax, float* bx, float* ay, float* by, float*
az, float* bz, int* nx, int* ny, int* nz, char* Bctype, float* q, int* ipar,
float* spar, int* stat);
```

Input Parameters

<p><i>ax</i></p>	<p>double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along x-axis.</p>
------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>bx</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along x-axis.
<i>ay</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along y-axis.
<i>by</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along y-axis.
<i>az</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>bz</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>nx</i>	int*. The number of mesh intervals along x-axis.
<i>ny</i>	int*. The number of mesh intervals along y-axis.
<i>nz</i>	int*. The number of mesh intervals along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>BCTYPE</i>	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ?_init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition) or 'D' (Dirichlet boundary

condition). Types of boundary conditions for the boundaries should be specified in the following order: bd_a_x , bd_b_x , bd_a_y , bd_b_y , bd_a_z , bd_b_z . Boundary condition types for the last two boundaries should be specified only in the 3D case.

q double* for
`d_init_Helmholtz_2D/d_init_Helmholtz_3D,`
float* for `s_init_Helmholtz_2D/s_init_Helmholtz_3D`
.
The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of q to 0.

Output Parameters

$ipar$ int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

$dpar$ double array of size $5 \times nx/2 + 7$ in the 2D case or $5 \times (nx + ny)/2 + 9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

$spar$ float array of size $5 \times nx/2 + 7$ in the 2D case or $5 \times (nx + ny)/2 + 9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

$stat$ int*. Routine completion status, which is also written to $ipar[0]$. The status should be 0 to proceed to other PL routines.

Description

The routines `?_init_Helmholtz_2D/?_init_Helmholtz_3D` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the $ipar$, $dpar$ and $spar$ array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING. Data structures initialized and created by 2D/3D flavors of the routine cannot be used by 3D/2D flavors of any PL routines, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

`stat= 0`

The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this `stat` value.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

?_commit_Helmholtz_2D/?_commit_Helmholtz_3D

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double*
bd_ay, double* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, double* dpar, int*
stat);
```

```
void s_commit_Helmholtz_2D (float* f, float* bd_ax, float* bd_bx, float*
bd_ay, float* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, float* spar, int*
stat);
```

```
void d_commit_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double*
bd_ay, double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, double* dpar, int* stat);
```

```
void s_commit_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float*
bd_ay, float* bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, float* spar, int* stat);
```

Input Parameters

<i>f</i>	<pre>double* for d_commit_Helmholtz_2D/d_com- mit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_com- mit_Helmholtz_3D.</pre> <p>Contains the right-hand side of the problem packed in a single vector.</p> <p>The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, the value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(nx+1)]$.</p> <p>The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(nx+1)+k*(nx+1)*(ny+1)]$.</p> <p>Note that to solve the Laplace problem, you should set all the elements of the array <i>f</i> to 0.</p> <p>Note also that the array <i>f</i> may be altered by the routine. To preserve the vector, save it in another memory location.</p>
<i>ipar</i>	<pre>int</pre> <p>array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<i>dpar</i>	<pre>double</pre> <p>array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<i>spar</i>	<pre>float</pre> <p>array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<i>bd_ax</i>	<pre>double* for d_commit_Helmholtz_2D/d_com- mit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_com- mit_Helmholtz_3D.</pre> <p>Contains values of the boundary condition on the leftmost boundary of the domain along <i>x</i>-axis.</p>

For `?_commit_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_ax[j]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_ax[j+k*(ny+1)]`.

`bd_bx`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

Contains values of the boundary condition on the rightmost boundary of the domain along x -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_bx[j]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_bx[j+k*(ny+1)]`.

`bd_ay`

```
double* for d_commit_Helmholtz_2D/d_com-
mit_Helmholtz_3D,
float* for s_commit_Helmholtz_2D/s_com-
mit_Helmholtz_3D.
```

Contains values of the boundary condition on the leftmost boundary of the domain along y -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCTYPE[2]` is 'D'), it contains values of the function $G(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of `BCTYPE[2]` is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in `bd_ay[i]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCTYPE[2]` is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCTYPE[2]` is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_ay[i+k*(nx+1)]`.

`bd_by`

```
double* for d_commit_Helmholtz_2D/d_com-
mit_Helmholtz_3D,
float* for s_commit_Helmholtz_2D/s_com-
mit_Helmholtz_3D.
```

Contains values of the boundary condition on the rightmost boundary of the domain along y -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCTYPE[3]` is 'D'), it contains values of the function $G(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of `BCTYPE[3]` is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in `bd_by[i]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCTYPE[3]` is 'D'), it contains values of the function

$G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[3]` is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_by[i+k*(nx+1)]`.

`bd_az`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i+j*(nx+1)]`.

`bd_bz`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i+j*(nx+1)]`.

Output Parameters

<i>f</i>	Vector of the right-hand side of the problem. Possibly, altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>xhandle, yhandle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>yhandle</i> is used only by <code>?_commit_Helmholtz_3D</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar</i> [0]. The status should be 0 to proceed to other PL routines.

Description

The routines `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines check consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize data structures *xhandle, yhandle* as well as arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications section](#). Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, the routines `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` are mandatory, and you cannot skip calling them in your code. Values of *ax, bx, ay, by, az, bz, nx, ny, nz*, and *BCTYPE* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

stat= 1

The routine completed without errors and produced some warnings.

stat = 0

The routine successfully completed the task.

```
stat= -100
```

The routine stopped because an error in the user's data was found or the data in the *dpar*, *spar* or *ipar* array was altered by mistake.

```
stat= -1000
```

The routine stopped because of an Intel MKL FFT or TT interface error.

```
stat= -10000
```

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

```
stat= -99999
```

The routine failed to complete the task because of a fatal error.

? Helmholtz 2D/? Helmholtz 3D

Computes the solution of 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, double* dpar, int* stat);
```

```
void s_Helmholtz_2D (float* f, float* bd_ax, float* bd_bx, float* bd_ay,
float* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, float* spar, int* stat);
```

```
void d_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, double* dpar, int* stat);
```

```
void s_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay,
float* bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, float* spar, int* stat);
```

Input Parameters

 f

```
double* for d_Helmholtz_2D/d_Helmholtz_3D,  
float* for s_Helmholtz_2D/s_Helmholtz_3D.
```

	<p>Contains the right-hand side of the problem packed in a single vector and modified by the appropriate <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, value of the right-hand side in the mesh point (i, j) is stored in <code>f[i+j*(nx+1)]</code>. The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in <code>f[i+j*(nx+1)+k*(nx+1)*(ny+1)]</code>.</p>
<code>xhandle, yhandle</code>	<p>DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “FFT Functions” in chapter “Fast Fourier Transforms”). <code>yhandle</code> is used only by <code>?_Helmholtz_3D</code>.</p>
<code>ipar</code>	<p>int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<code>dpar</code>	<p>double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<code>spar</code>	<p>float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<code>bd_ax</code>	<p>double* for <code>d_Helmholtz_2D/d_Helmholtz_3D</code>, float* for <code>s_Helmholtz_2D/s_Helmholtz_3D</code>. Contains values of the boundary condition on the leftmost boundary of the domain along x-axis. For <code>?_Helmholtz_2D</code>, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in <code>bd_ax[j]</code>.</p>

For `?_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_ax[j+k*(ny+1)]`.

`bd_bx`

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 Contains values of the boundary condition on the rightmost boundary of the domain along x -axis.
 For `?_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_bx[j]`.

For `?_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_bx[j+k*(ny+1)]`.

`bd_ay`

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 Contains values of the boundary condition on the leftmost boundary of the domain along y -axis.
 For `?_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCtype[2]` is 'D'), it contains values of the function $G(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of

$BCtype[2]$ is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in $bd_ay[i]$.

For $?_Helmholtz_3D$, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCtype[2]$ is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCtype[2]$ is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in $bd_ay[i+k*(nx+1)]$.

bd_by

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 Contains values of the boundary condition on the rightmost boundary of the domain along y -axis.

For $?_Helmholtz_2D$, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of $BCtype[3]$ is 'D'), it contains values of the function $G(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of $BCtype[3]$ is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in $bd_by[i]$.

For $?_Helmholtz_3D$, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCtype[3]$ is 'D'), it contains values of the function $G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCtype[3]$ is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in $bd_by[i+k*(nx+1)]$.

bd_az

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 This parameter is needed only for $?_Helmholtz_3D$.
 Contains values of the boundary condition on the leftmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCTYPE[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCTYPE[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i+j*(nx+1)]`.

`bd_bz` double* for `d_Helmholtz_2D/d_Helmholtz_3D`, float* for `s_Helmholtz_2D/s_Helmholtz_3D`. This parameter is needed only for `?_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along z -axis. The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCTYPE[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCTYPE[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i+j*(nx+1)]`.

NOTE. To avoid wrong computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>xhandle, yhandle</code>	Data structures used by the Intel MKL FFT interface.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .

<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>stat</i>	<i>int*</i> . Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines compute the approximate solution of Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *ax*, *bx*, *ay*, *by*, *az*, *bz*, *nx*, *ny*, *nz*, and *BCtype* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the memory was insufficient to complete the computations.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of the Intel MKL FFT or TT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

free_Helmholtz_2D/free_Helmholtz_3D

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR* xhandle, int* ipar, int* stat);
void free_Helmholtz_3D (DFTI_DESCRIPTOR* xhandle, DFTI_DESCRIPTOR* yhandle,
int* ipar, int* stat);
```

Input Parameters

<code>xhandle, yhandle</code>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). The structure <code>yhandle</code> is used only by <code>free_Helmholtz_3D</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

Output Parameters

<code>xhandle, yhandle</code>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Status of the routine call is written to <code>ipar[0]</code> .
<code>stat</code>	int*. Routine completion status, which is also written to <code>ipar[0]</code> .

Description

The routine is declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routine cleans the memory used by the `xhandle` and `yhandle` structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

PL Routines for the Spherical Solver

The section gives detailed description of spherical PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, periodic (having names ending in "p") and non-periodic (having names ending in "np"), are described together.

These PL routines also call the Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_sph_p/?_init_sph_np

Initializes basic data structures of the Fast periodic and non-periodic Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p(double* ap, double* at, double* bp, double* bt, int* np,
int* nt, double* q, int* ipar, double* dpar, int* stat);
```

```
void s_init_sph_np(float* ap, float* at, float* bp, float* bt, int* np, int*
nt, float* q, int* ipar, float* spar, int* stat);
```

```
void d_init_sph_np(double* ap, double* at, double* bp, double* bt, int* np,
int* nt, double* q, int* ipar, double* dpar, int* stat);
```

```
void s_init_sph_np(float* ap, float* at, float* bp, float* bt, int* np, int*
nt, float* q, int* ipar, float* spar, int* stat);
```

Input Parameters

<i>ap</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along ϕ -axis.
<i>bp</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along ϕ -axis.
<i>at</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along θ -axis.
<i>bt</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along θ -axis.
<i>np</i>	int*. The number of mesh intervals along ϕ -axis. Must be even in the periodic case.
<i>nt</i>	int*. The number of mesh intervals along θ -axis.
<i>q</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The constant Helmholtz coefficient. Note that to solve Poisson problem, you should set the value of <i>q</i> to 0.

Output Parameters

<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

<i>spar</i>	float array of size $5 \cdot n_p/2 + n_t + 10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines `?_init_sph_p/?_init_sph_np` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING. Data structures initialized and created by periodic/non-periodic flavors of the routine cannot be used by non-periodic/periodic flavors of any PL routines for Helmholtz Solver on a sphere, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of fatal error.

?_commit_sph_p/?_commit_sph_np

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR*
handle_c, int* ipar, double* dpar, int* stat);

void s_commit_sph_p(float* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR*
handle_c, int* ipar, float* spar, int* stat);

void d_commit_sph_np(double* f, DFTI_DESCRIPTOR* handle, int* ipar, double*
dpar, int* stat);

void s_commit_sph_np(float* f, DFTI_DESCRIPTOR* handle, int* ipar, float*
spar, int* stat);
```

Input Parameters

<i>f</i>	double* for d_commit_sph_p/d_commit_sph_np, float* for s_commit_sph_p/s_commit_sph_np. Contains the right-hand side of the problem packed in a single vector. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$. Note that the array <i>f</i> may be altered by the routine. Please save this vector in another memory location if you want to preserve it.
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>f</i>	Vector of the right-hand side of the problem. Possibly, altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar</i> [0]. The status should be 0 to proceed to other PL routines.

Description

The routines `?_commit_sph_p/?_commit_sph_np` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle_s* and *handle_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_sph_p/?_init_sph_np`, the routines `?_commit_sph_p/?_commit_sph_np` are mandatory, and you cannot skip calling them in your code. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate `?_init_sph_p/?_init_sph_np` routine.

Return Values

`stat= 1`

The routine completed without errors and produced some warnings.

`stat= 0`

The routine successfully completed the task.

`stat= -100`

The routine stopped because an error in the user's data was found or the data in the `dpar`, `spar` or `ipar` array was altered by mistake.

`stat= -1000`

The routine stopped because of an Intel MKL FFT or TT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

?_sph_p/?_sph_np

Computes the solution of a spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c,
int* ipar, double* dpar, int* stat);
```

```
void s_sph_p(float* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c,
int* ipar, float* spar, int* stat);
```

```
void d_sph_np(double* f, DFTI_DESCRIPTOR* handle, int* ipar, double* dpar,
int* stat);
```

```
void s_sph_np(float* f, DFTI_DESCRIPTOR* handle, int* ipar, float* spar, int*
stat);
```

Input Parameters

`f` double* for `d_sph_p/d_sph_np`,
float* for `s_sph_p/s_sph_np`.

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_sph_p/?_commit_sph_np` routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$.

<code>handle_s, handle_c, handle</code>	DESCRIPTOR_HANDLE*. Data structures used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <code>handle_s</code> and <code>handle_c</code> are used only in <code>?_sph_p</code> and <code>handle</code> is used only in <code>?_sph_np</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<code>dpar</code>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<code>spar</code>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>handle_s, handle_c, handle</code>	Data structures used by the Intel MKL FFT interface.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<code>dpar</code>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .

<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate `?_init_sph_p/?_init_sph_np` routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the memory was insufficient to complete the computations.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
<i>stat</i> = -10000	The routine stopped because the initialization failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c, int*
ipar, int* stat);

void free_sph_np(DFTI_DESCRIPTOR* handle, int* ipar, int* stat);
```

Input Parameters

<i>handle_s, handle_c,</i> <i>handle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). The structures <i>handle_s</i> and <i>handle_c</i> are used only in <i>free_sph_p</i> , and <i>handle</i> is used only in <i>free_sph_np</i> .
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>handle_s, handle_c,</i> <i>handle</i>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> .

Description

The routine is declared in the `mk1_poisson.h` header file for the C interface and `mk1_poisson.f90` header file for the Fortran interface. The routine cleans the memory used by the *handle_s*, *handle_c* or *handle* structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of the Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

Common Parameters

This section provides description of array parameters *ipar*, *dpar* and *spar*, which hold PL routine options in both Cartesian and spherical cases.

NOTE. Initial values are assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

<i>ipar</i>	int array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in Table 13-6 :
-------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Table 13-6 Elements of the ipar Array

Index	Description
0	Contains status value of the last called PL routine. In general, it should be 0 to proceed with Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see Figure 13-3). A non-zero value of <i>ipar</i> [0] with decimal representation

$$\overline{abc} = 100a + 10b + c$$

where each of *a*, *b*, and *c* is equal to 0 or 9, indicates that some parts of the Commit step should be omitted.

Index	Description
	<ul style="list-style-type: none">• If $c=9$, the routine omits checking of parameters and initialization of the data structures.• If $b=9$, then in the Cartesian case, the routine omits the adjustment of the right-hand side vector f to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function g) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function g). In this case, the routine also omits the adjustment of the right-hand side vector f to the particular boundary functions. For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the $dpar/spar$ array.• If $a=9$, then the routine omits the normalization of the right-hand side vector f. In the 2D Cartesian case, it is the multiplication by h_y^2, where h_y is the mesh size in the y direction (for details, see Poisson Library Implemented). In the 3D (Cartesian) case, it is the multiplication by h_z^2, where h_z is the mesh size in the z direction. For the Helmholtz solver on a sphere, it is the multiplication by h_θ^2, where h_θ is the mesh size in the θ direction (for details, see Poisson Library Implemented).

Using `ipar[0]` you can adjust the routine to your needs and gain efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious using this opportunity, because misunderstanding of the commit process may cause wrong results or program failure (see also [Caveat on Parameter Modifications](#)).

- 1

Contains error messaging options:

 - `ipar[1]=-1` indicates that all error messages will be printed to the file `MKL_Poisson_Library_log.txt` in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device.
 - `ipar[1]=0` indicates that no error messages will be printed.
 - `ipar[1]=1` is the default value. It indicates that all error messages will be printed to the preconnected default output device (usually, screen).

In case of errors, the `stat` parameter will acquire a non-zero value regardless of the `ipar[1]` setting.
- 2

Contains warning messaging options:

Index	Description
	<ul style="list-style-type: none"> • <i>ipar[2]</i>=-1 indicates that all warning messages will be printed to the file <code>MKL_Poisson_Library_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[2]</i>=0 indicates that no warning messages will be printed. • <i>ipar[2]</i>=1 is the default value. It indicates that all warning messages will be printed to the preconnected default output device (usually, screen). <p>In case of warnings, the <i>stat</i> parameter will acquire a non-zero value regardless of the <i>ipar[2]</i> setting.</p>
3	<p>Contains the number of the combination of boundary conditions. In the Cartesian case, it corresponds to the value that the <i>BCtype</i> parameter holds:</p> <ul style="list-style-type: none"> • In the 2D case, <ul style="list-style-type: none"> 0 corresponds to 'DDDD' 1 corresponds to 'DDDN' ... 15 corresponds to 'NNNN' • In the 3D case, <ul style="list-style-type: none"> 0 corresponds to 'DDDDDD' 1 corresponds to 'DDDDDN' ... 63 corresponds to 'NNNNNN'. <p>The Helmholtz solver on a sphere uses this parameter only in a periodic case. The <i>bp</i> and <i>bt</i> parameters of the ?_init_sph_p/?_init_sph_np routine, which initializes <i>ipar[3]</i>, determine its value:</p> <ul style="list-style-type: none"> • 0 corresponds to the problem without poles. • 1 corresponds to the problem on the entire sphere. <p>Parameters 4 through 9 are used only in Cartesian case.</p>
4	Takes the value of 1 if <i>BCtype[0]</i> ='N', 0 if <i>BCtype[0]</i> ='D', and -1 otherwise.
5	Takes the value of 1 if <i>BCtype[1]</i> ='N', 0 if <i>BCtype[1]</i> ='D', and -1 otherwise.

Index	Description
6	Takes the value of 1 if $B\text{Ctype}[2]='N'$, 0 if $B\text{Ctype}[2]='D'$, and -1 otherwise.
7	Takes the value of 1 if $B\text{Ctype}[3]='N'$, 0 if $B\text{Ctype}[3]='D'$, and -1 otherwise.
8	Takes the value of 1 if $B\text{Ctype}[4]='N'$, 0 if $B\text{Ctype}[4]='D'$, and -1 otherwise. This parameter is used only in the 3D case.
9	Takes the value of 1 if $B\text{Ctype}[5]='N'$, 0 if $B\text{Ctype}[5]='D'$, and -1 otherwise. This parameter is used only in the 3D case.
10	Takes the value of <ul style="list-style-type: none"> nx, that is, the number of intervals along x-axis, in the Cartesian case. np, that is, the number of intervals along ϕ-axis, in the spherical case.
11	Takes the value of <ul style="list-style-type: none"> ny, that is, the number of intervals along y-axis, in the Cartesian case nt, that is, the number of intervals along θ-axis, in the spherical case.
12	Takes the value of nz , the number of intervals along z -axis. This parameter is used only in the 3D case (Cartesian).
13	Takes the value of 6, which specifies the internal partitioning of the $dpar/spar$ array.
14	Takes the value of $ipar[13]+ipar[10]+1$, which specifies the internal partitioning of the $dpar/spar$ array.

Subsequent values of $ipar$ depend upon the dimension of the problem or upon whether the solver on a sphere is periodic.

	2D case	3D case	Periodic case	Non-periodic case
15	Unused		Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the $dpar/spar$ array.	
16	Unused		Takes the value of $ipar[14]+ipar[11]+1$, which specifies the internal partitioning of the $dpar/spar$ array.	

Index	Description			
17	Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.		
18	Takes the value of $ipar[14]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/4+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.
19	Unused	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.		Unused
20	Unused	Takes the value of $ipar[18]+3*ipar[11]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[18]+3*ipar[10]/4+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Unused
Subsequent values of <i>ipar</i> are assigned regardless.				
21	Contains message style options: <ul style="list-style-type: none"> $ipar[21]=0$ indicates that PL routines print all error and warning messages in Fortran-style notations. $ipar[21]=1$ (default) indicates that PL routines print the messages in C-style notations. 			
22	Contains the number of threads to be used for computations in a multithreaded environment. The default value is 1.			

Index	Description
23 through 39	Unused in the current implementation of the Poisson Library.
40 through 59	Contain the first twenty elements of the <i>ipar</i> array of the first Trigonometric Transform that the Solver uses. (For details, see Common Parameters in the “Trigonometric Transform Routines” chapter.)
60 through 79	Contain the first twenty elements of the <i>ipar</i> array of the second Trigonometric Transform that the 3D and periodic solvers use. (For details, see Common Parameters in the “Trigonometric Transform Routines” chapter.)

NOTE. You may declare the *ipar* array in your code as `int ipar[80]`. However, for compatibility with later versions of Intel MKL Poisson Library, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	<p>Holds data needed for double-precision Fast Helmholtz Solver computations.</p> <ul style="list-style-type: none">• For the Cartesian solver, <code>double</code> array of size $5 \cdot n_x/2 + 7$ in the 2D case or $5 \cdot (n_x + n_y)/2 + 9$ in the 3D case; initialized in the <code>d_init_Helmholtz_2D/d_init_Helmholtz_3D</code> and <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> routines.• For the spherical solver, <code>double</code> array of size $5 \cdot n_p/2 + n_t + 10$; initialized in the <code>d_init_sph_p/d_init_sph_np</code> and <code>d_commit_sph_p/d_commit_sph_np</code> routines.
<i>spar</i>	<p>Holds data needed for single-precision Fast Helmholtz Solver computations.</p> <ul style="list-style-type: none">• For the Cartesian solver, <code>float</code> array of size $5 \cdot n_x/2 + 7$ in the 2D case or $5 \cdot (n_x + n_y)/2 + 9$ in the 3D case; initialized in the <code>s_init_Helmholtz_2D/s_init_Helmholtz_3D</code> and <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> routines.• For the spherical solver, <code>float</code> array of size $5 \cdot n_p/2 + n_t + 10$; initialized in the <code>s_init_sph_p/s_init_sph_np</code> and <code>s_commit_sph_p/s_commit_sph_np</code> routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table 13-7:

Table 13-7 Elements of the *dpar* and *spar* Arrays

Index	Description
0	<p>In the Cartesian case, contains the length of the interval along x-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_x in the x direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along ϕ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_ϕ in the ϕ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
1	<p>In the Cartesian case, contains the length of the interval along y-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_y in the y direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along θ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_θ in the θ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
2	<p>In the Cartesian case, contains the length of the interval along z-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_z in the z direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the Cartesian solver, this parameter is used only in the 3D case.</p> <p>In the spherical solver, contains the coordinate of the leftmost boundary along θ-axis after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine.</p>
3	<p>Contains the value of the coefficient q after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.</p>

Index	Description
4	<p>Contains the tolerance parameter after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.</p> <ul style="list-style-type: none"> In the Cartesian case, this value is used only for the pure Neumann boundary conditions (<code>BCTYPE="NNNN"</code> in the 2D case; <code>BCTYPE="NNNNNN"</code> in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient q is zero. Poisson Library verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, Poisson Library computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the <code>?_Helmholtz_2D/?_Helmholtz_3D</code> routine informs the user that the solution may not exist in a classical sense (up to rounding errors). In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the above described Cartesian case with pure Neumann boundary conditions. So, here Poisson Library computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors. <p>The default value for this parameter is 1.0E-10 in case of double-precision computations or 1.0E-4 in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.</p>
<code>ipar[13]-1</code> through <code>ipar[14]-1</code>	<p>In the Cartesian case, contain the spectrum of the 1D problem along x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the spectrum of the 1D problem along ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
<code>ipar[15]-1</code> through <code>ipar[16]-1</code>	<p>In the Cartesian case, contain the spectrum of the 1D problem along y-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. These elements are used only in the 3D case.</p> <p>In the spherical case, contains the spherical weights after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>

Index	Description
<i>ipar</i> [17]-1 through <i>ipar</i> [18]-1	<p>Take the values of the (staggered) sine/cosine in the mesh points:</p> <ul style="list-style-type: none"> • along <i>x</i>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian solver • along ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine for a spherical solver.
<i>ipar</i> [19]-1 through <i>ipar</i> [20]-1	<p>Take the values of the (staggered) sine/cosine in the mesh points:</p> <ul style="list-style-type: none"> • along <i>y</i>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian 3D solver • along ϕ-axis after a call to the <code>?_commit_sph_p</code> routine for a spherical periodic solver. <p>These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.</p>

NOTE. You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the PL interface enables you to skip calling the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE. To supply correct and consistent parameters to PL routines, you should have considerable experience in using the PL interface and good understanding of the solution process as well as elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail in tuning parameters for the Fast Helmholtz Solver. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING. The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL PL interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the PL language-specific header files to include in their code. Currently, the following header files are available:

- `mkl_poisson.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_poisson.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE. Use of the Intel MKL PL software without including one of the above header files is not supported.

The include files define function prototypes for appropriate languages.

C-specific Header File

The C-specific header file defines the following function prototypes for the Cartesian solver:

```
void d_init_Helmholtz_2D(double*, double*, double*, double*, int*, int*, char*, double*,
int*, double*, int*);
```

```
void d_commit_Helmholtz_2D(double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);
```

```
void d_Helmholtz_2D(double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*,
int*, double*, int*);

void s_init_Helmholtz_2D(float*, float*, float*, float*, int*, int*, char*, float*, int*,
float*, int*);

void s_commit_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*,
int*, float*, int*);
```

```

void s_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, int*,
float*, int*);

void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE*, int*, int*);

void d_init_Helmholtz_3D(double*, double*, double*, double*, double*, double*, int*, int*,
int*, char*, double*, int*, double*, int*);

void d_commit_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_Helmholtz_3D(float*, float*, float*, float*, float*, float*, int*, int*, int*,
char*, float*, int*, float*, int*);

void s_commit_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void s_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);

```

The C-specific header file defines the following function prototypes for the spherical solver:

```

void d_init_sph_p(double*, double*, double*, double*, int*, int*, double*, int*, double*,
int*);

void d_commit_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*,
int*);

void d_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*,
int*);

void s_init_sph_p(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);

void s_commit_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*,
int*);

void s_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_sph_p(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);

void d_init_sph_np(double*, double*, double*, double*, int*, int*, double*, int*, double*,
int*);

void d_commit_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_sph_np(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);

void s_commit_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

```

```
void s_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);
void free_sph_np(DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes for the Cartesian solver:

```
SUBROUTINE D_INIT_HELMHOLTZ_2D (AX, BX, AY, BY, NX, NY, BCTYPE, Q, IPAR, DPAR, STAT)

Fortran 90 specifics of the PL routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Calling PDE Support Routines from Fortran 90

The calling interface for all the Intel MKL TT and PL routines is designed to be easily used in C. However, you can invoke each TT or PL routine directly from Fortran 90 if you are familiar with the inter-language calling conventions of your platform.

The TT or PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of the Intel MKL FFT interface.

The inter-language calling conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from C to Fortran 90 and how C external names are decorated on the platform.

To promote portability and relieve a user of dealing with the calling conventions specifics, Fortran 90 header file `mkl_trig_transforms.f90` for TT routines and `mkl_poisson.f90` for PL routines, used together with `mkl_dfti.f90`, declare a set of macros and introduce type definitions intended to hide the inter-language calling conventions and provide an interface to the routines that looks natural in Fortran 90.

For example, consider a hypothetical library routine, `foo`, which takes a double-precision vector of length `n`. C users access such a function as follows:

```

int n;

double *x;

...

foo(x, &n);

```

As noted above, to invoke `foo`, Fortran 90 users would need to know what Fortran 90 data types correspond to C types `int` and `double` (or `float` in case of single-precision), what argument-passing mechanism the C compiler uses and what, if any, name decoration is performed by the C compiler when generating the external symbol `foo`. However, with the Fortran 90 header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` included, the invocation of `foo` within a Fortran 90 program will look as follows:

- For TT interface,

```
use mkl_dfti
use mkl_trig_transforms
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

- For PL interface,

```
use mkl_dfti
use mkl_poisson
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

Note that in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` provide a definition for the subroutine `FOO`. To ease the use of PL or TT routines in Fortran 90, the general approach of providing Fortran 90 definitions of names is used throughout the libraries. Specifically, if a name from a PL or TT interface is documented as having the C-specific name `foo`, then the Fortran 90 header files provide an appropriate Fortran 90 language type definition `FOO`.

One of the key differences between Fortran 90 and C is the language argument-passing mechanism: C programs use pass-by-value semantics and Fortran 90 programs use pass-by-reference semantics. The Fortran 90 headers ensure proper treatment of this difference. In particular, in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` hide the difference by defining a macro `FOO` that takes the address of the appropriate arguments.

Optimization Solver Routines

Intel® Math Kernel Library provides tools for solving optimization problems. These tools are routines for solving nonlinear least squares problems through the Trust-Region (TR) algorithms.

Intel MKL provides the optimization solver routines that can be used for:

- solving nonlinear least squares problems without constraints
- solving nonlinear least squares problems with boundary constraints
- computing the Jacobi matrix by central differences for solving nonlinear least squares problem

The first two groups of routines are designed to find only one local minimum point. However problems can have multiple local minima and trying different initial points is recommended for better solutions.

For more information on terms and key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [Appendix F, “Optimization Solvers Basics”](#).

Routines described below are subdivided according to their purpose as follows:

[Nonlinear Least Squares Problem without Constraints](#)

[Nonlinear Least Squares Problem with Linear \(Boundary\) Constraints](#)

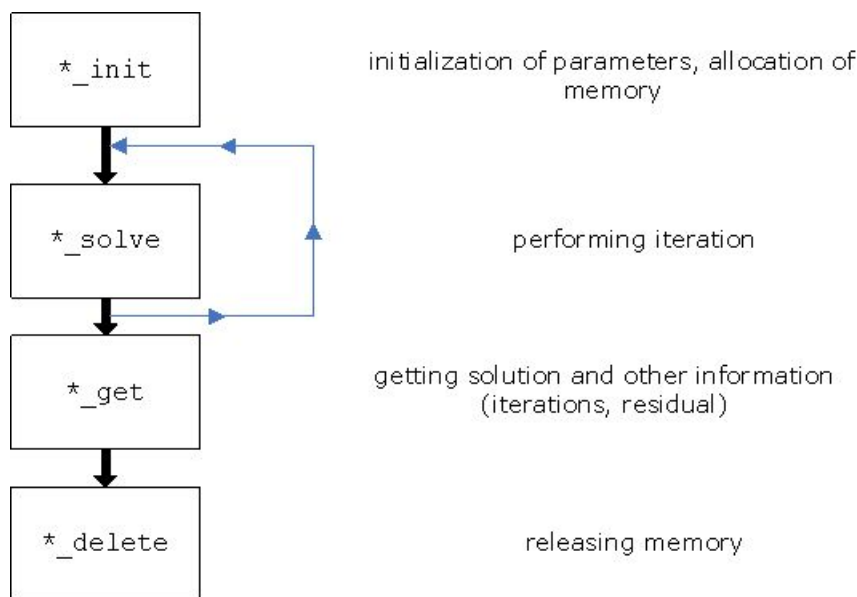

[Jacobi Matrix Calculation Routines](#).

Organization and Implementation

The TR solvers have RCI-based interfaces. The RCI TR interface implements a group of user-callable routines that are used in the step-by-step solving process for nonlinear least squares problem and follows the general RCI scheme described in [[Dong95](#)]. RCI means that the user is supposed to perform certain operations for the solver, for example, to provide values of the objective function

or a Jacobi matrix. When the solver needs the results of such operations, the user should pass them to the solver. This makes the solver independent of specific implementation of the operations. However, this approach requires some additional work by the user.

Figure 14-1 Typical order for invoking RCI solver routines

The Trust-Region solvers are implemented with OpenMP* support. To use the multiprocessing mode, set the number of threads in environment variable `OMP_NUM_THREADS`.

Memory Allocation and Handles

To make the routines easy to use, you are not required to allocate temporary working storage. Any required memory is allocated by the solver. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using an opaque data object called a *handle*. Each of the Intel RCI TR solver routine creates, uses or deletes a handle.

Handle declaration varies from language to language. This document declares it as to be of `_TRNSP_HANDLE_t` or `_TRNSPBC_HANDLE_t` type.

C and C++ programmers should declare a handle as:

```
#include "mkl_rci.h"

_TRNSP_HANDLE_t handle;

or

_TRNSPBC_HANDLE_t handle;
```

Fortran programmers using compilers that support eight byte integers should declare a handle as:

```
INCLUDE "mkl_rci.fi"

INTEGER*8 handle
```

In addition to the necessary definition, for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the error returns
- user options for the solver routines
- message severity.

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in R^n} F(x) = \|y - f(x)\|_2^2, y \in R^m, x \in R^n, f: R^n \rightarrow R^m, m > n,$$

where $F(x) : R^n \rightarrow R$ is a twice differentiable function in R^n . Solving of the nonlinear least squares problem is searching for the best approximation to vector y with model function $f_i(x)$, which has nonlinear dependence on variables x . The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the lowest possible.

Table 14-1 RCI TR Routines

Routine Name	Operation
dtrnlsp_init	Initializes the solver.

Routine Name	Operation
<code>dtrnlsp_solve</code>	Solves a nonlinear least squares problem on the basis of RCI using the Trust-Region algorithm.
<code>dtrnlsp_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>dtrnlsp_delete</code>	Removes data.

dtrnlsp_init

Initializes the solver of nonlinear least squares problem.

Syntax

Fortran:

```
res = dtrnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
```

C:

```
res = dtrnlsp_init(&handle, &n, &m, x, eps, &iter1, &iter2, &rs);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine initializes the solver. After initialization all subsequent invocations of the `dtrnlsp_solve` routine should use the values of the handle returned by `dtrnlsp_init`.

The `eps` array contains the stopping tests:

`eps(1)`: $\Delta_k < \text{eps}(1)$

`eps(2)`: $||F(x)|| < \text{eps}(2)$

`eps(3)`: $||A(x)_{ij}|| < \text{eps}(3)$

`eps(4)`: $||s|| < \text{eps}(4)$

`eps(5)`: $||F(x)|| - ||F(x) - A(x)s|| < \text{eps}(5)$

`eps(6)`: the trial step precision. If `eps(6) = 0`, then `eps(6) = 1.d-10`,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

<i>n</i>	INTEGER. Length of X .
<i>m</i>	INTEGER. Length of $F(x)$.
<i>x</i>	DOUBLE PRECISION. Array of size n . Initial guess.
<i>eps</i>	DOUBLE PRECISION. Array of size 6; contains stopping tests. See the values in Description.
<i>iter1</i>	INTEGER. Specifies the maximum number of iterations.
<i>iter2</i>	INTEGER. Specifies the maximum number of iterations of trial-step calculation.
<i>rs</i>	DOUBLE PRECISION. Positive input variable used in determining the initial step bound. In most cases the factor should lie within the interval (0.1, 100.0). The generally recommended value is 100.

Output Parameters

<i>handle</i>	Data object of the <code>_TRNSP_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = <code>TR_SUCCESS</code> means the routine completed the task normally. <i>res</i> = <code>TR_INVALID_OPTION</code> means an error in the input parameters. <i>res</i> = <code>TR_OUT_OF_MEMORY</code> means a memory error.

dtrnlsp_solve

Solves a nonlinear least squares problem using the Trust-Region algorithm.

Syntax

Fortran:

```
res = dtrnlsp_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = dtrnlsp_solve(&handle, fvec, fjac, &RCI_Request);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface.

The `dtrnlsp_solve` routine, based on Reverse Communication Interface (RCI), uses the Trust-Region algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \frac{1}{2} F(x)^T F(x) = \frac{1}{2} \sum_{i=1}^m f_i(x)^2,$$

where $m \geq n$, $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and $f_i(x)$ is the i -th component function of $F(x)$. From a current point, the algorithm uses the trust-region approach:

$$\min_{x \in \mathbb{R}^n} \|F(x_c) + J(x_c)(x_n - x_c)\| \quad \text{subject to} \quad \|x_n - x_c\|_2 \leq \Delta_c$$

to get the new point x_n as the solution to the following problem:

$$\min_{x \in \mathbb{R}^n} \|J^T(x)J(x) + J^T F(x)s\|_2,$$

where s is the trial step, and $\|s\|_2 \leq \Delta_c$,

then $x_n = x_c + s$.

The `RCI_Request` parameter informs about the task completion and may have the following values:

`RCI_Request`= 2 that indicates the requirement to calculate the Jacobian matrix and put the result into `fjac`.

`RCI_Request`= 1 that indicates the requirement to recalculate the function at vector `x` and put the result into `fvec`.

`RCI_Request`= 0 that indicates successful completion of the task

`RCI_Request`= -1 indicating that the algorithm has exceeded the maximal number of iterations.

$RCI_Request = -2$ indicating that $\Delta_k < eps(1)$

$RCI_Request = -3$ indicating that $||F(x)|| < eps(2)$

$RCI_Request = -4$ indicating that $||A(x)_{ij}|| < eps(3)$

$RCI_Request = -5$ indicating that $||s|| < eps(4)$

$RCI_Request = -6$ indicating that $||F(x)|| - ||F(x) - A(x)s|| < eps(5)$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

<i>handle</i>	Data object of the <code>_TRNSP_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the function values at X , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	DOUBLE PRECISION. Array of size (m,n) . Contains the Jacobi matrix of the function.

Output Parameters

<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the updated function values at x
<i>RCI_Request</i>	INTEGER. Informs about the task completion. When equal to 0, the task is completed successfully. See Description for the other values of the parameter and their meaning.
<i>res</i>	INTEGER. Informs about the task completion. $res = TR_SUCCESS$ means the routine completed the task normally.

dtrnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = dtrnlsp_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = dtrnlspl_get(&handle, &iter, &st_cr, &r1, &r2);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine retrieves the current number of iterations, stop criterion, initial residual, and final residual.

The `st_cr` parameter contains the stop criterion:

`st_cr = 1` indicates that the algorithm has exceeded the maximal number of iterations.

`st_cr = 2` indicates that $\Delta_k < \text{eps}(1)$

`st_cr = 3` indicates that $\|F(x)\| < \text{eps}(2)$

`st_cr = 4` indicates that $\|A(x)_{ij}\| < \text{eps}(3)$

`st_cr = 5` indicates that $\|s\| < \text{eps}(4)$

`st_cr = 6` indicates that $\|F(x)\| - \|F(x) - A(x)s\| < \text{eps}(5)$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, and s is the trial step.

Input Parameters

<i>handle</i>	Data object of the <code>_TRNSP_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
---------------	------------------------------------------------------------------------------------------------------

Output Parameters

<i>iter</i>	INTEGER. Contains the current number of iterations.
<i>st_cr</i>	INTEGER. Contains the stop criterion. See Description for the parameter values and their meanings.
<i>r1</i>	DOUBLE PRECISION. Contains the initial residual, that is, the value of the functional $\ y - f(x)\ $ of the initial x set by the user.
<i>r2</i>	DOUBLE PRECISION. Contains the final residual, that is, the value of the functional $\ y - f(x)\ $ of the final x resulting from the algorithm operation.
<i>res</i>	INTEGER. Informs about the task completion.

`res = TR_SUCCESS` means the routine completed the task normally.

dtrnlsp_delete

Removes the data object required by the TR solver.

Syntax

Fortran:

```
res = dtrnlsp_delete(handle)
```

C:

```
res = dtrnlsp_delete(&handle);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine removes the data object needed for the RCI TR solver.

Input Parameters

<code>handle</code>	Data object of the <code>_TRNSP_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
---------------------	------------------------------------------------------------------------------------------------------

Output Parameters

<code>res</code>	INTEGER. Informs about the task completion. <code>res = TR_SUCCESS</code> means the routine completed the task normally.
------------------	-----------------------------------------------------------------------------------------------------------------------------

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints can be described and solved in the same way as the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, n, \quad l, u \in R^n.$$

Table 14-2 RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
<code>dtrnlsdbc_init</code>	Initializes the solver.
<code>dtrnlsdbc_solve</code>	Solves a nonlinear least squares problem on the basis of RCI using the Trust-Region algorithm.
<code>dtrnlsdbc_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>dtrnlsdbc_delete</code>	Removes data.

dtrnlsdbc_init

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

Fortran:

```
res = dtrnlsdbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
```

C:

```
res = dtrnlsdbc_init(&handle, &n, &m, x, LW, UP, eps, &iter1, &iter2, &rs);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine initializes the solver. After initialization all invocations of the `dtrnlsdbc_solve` routine should use the values of the handle returned by `dtrnlsdbc_init`.

The `eps` array contains the stopping tests:

```
eps(1):  $\Delta_k < eps(1)$ 
eps(2):  $||F(x)|| < eps(2)$ 
eps(3):  $||A(x)_{ij}|| < eps(3)$ 
eps(4):  $||s|| < eps(4)$ 
```

$eps(5) : ||F(x)|| - ||F(x) - A(x)s|| < eps(5)$

$eps(6)$: the trial step precision. If $eps(6) = 0$, then $eps(6) = 1.d-10$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

n	INTEGER. Length of x .
m	INTEGER. Length of $F(x)$.
x	DOUBLE PRECISION. Array of size n . Initial guess.
LW	DOUBLE PRECISION. Array of size n . Contains low bounds for x ($lw_i \leq x_i$).
UP	DOUBLE PRECISION. Array of size n . Contains upper bounds for x ($up_i \leq x_i$).
eps	DOUBLE PRECISION. Array of size 6; contains stopping tests. See the values in Description.
$iter1$	INTEGER. Specifies the maximum number of iterations.
$iter2$	INTEGER. Specifies the maximum number of iterations of trial-step calculation.
rs	DOUBLE PRECISION. Positive input variable used in determining the initial step bound. In most cases the factor should lie within the interval (0.1, 100.0). The generally recommended value is 100.

Output Parameters

$handle$	Data object of the <code>_TRNSPBC_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
res	INTEGER. Informs about the task completion. $res = TR_SUCCESS$ indicates that the routine has completed the task normally. $res = TR_INVALID_OPTION$ indicates an error in the input parameters. $res = TR_OUT_OF_MEMORY$ indicates a memory error.

dtrnlspbc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

Fortran:

```
res = dtrnlspbc_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = dtrnlspbc_solve(&handle, fvec, fjac, &RCI_Request);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The `dtrnlspbc_solve` routine, based on Reverse Communication Interface (RCI), uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \frac{1}{2} F(x)^T F(x) = \frac{1}{2} \sum_{i=1}^m f_i(x)^2, \text{ where } l_i \leq x_i \leq u_i, i = 1, \dots, n,$$

where $m \geq n$, $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and $f_i(x)$ is the i -th component function of $F(x)$.

The `RCI_Request` parameter informs about the task completion and may have the following values:

`RCI_Request = 2` that indicates the requirement to calculate the Jacobian matrix and put the result into `fjac`.

`RCI_Request = 1` that indicates the requirement to recalculate the function at vector `x` and put the result into `fvec`.

`RCI_Request = 0` that indicates successful completion of the task

`RCI_Request = -1` indicating that the algorithm has exceeded the maximal number of iterations.

`RCI_Request = -2` indicating that $\Delta_k < \text{eps}(1)$

$RCI_Request = -3$ indicating that $||F(x)|| < eps(2)$

$RCI_Request = -4$ indicating that $||A(x)_{ij}|| < eps(3)$

$RCI_Request = -5$ indicating that $||s|| < eps(4)$

$RCI_Request = -6$ indicating that $||F(x)|| - ||F(x) - A(x)s|| < eps(5)$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

<i>handle</i>	Data object of the <code>_TRNSPBC_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the function values at X , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	DOUBLE PRECISION. Array of size m by n . Contains the Jacobi matrix of the function.

Output Parameters

<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the updated function values at X
<i>RCI_Request</i>	INTEGER. Informs about the task completion. When equal to 0, the task is completed successfully. See Description for the other values of the parameter and their meaning.
<i>res</i>	INTEGER. Informs about the task completion. $res = TR_SUCCESS$ means the routine completed the task normally.

dtrnlspsc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = dtrnlspsc_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = dtrnlspsc_get(&handle, &iter, &st_cr, &r1, &r2);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine retrieves the current number of iterations, stop criterion, initial residual, and final residual.

The `st_cr` parameter contains the stop criterion:

`st_cr = 1` indicates that the algorithm has exceeded the maximal number of iterations.

`st_cr = 2` indicates that $\Delta_k < \text{eps}(1)$

`st_cr = 3` indicates that $\|F(x)\| < \text{eps}(2)$

`st_cr = 4` indicates that $\|A(x)_{ij}\| < \text{eps}(3)$

`st_cr = 5` indicates that $\|s\| < \text{eps}(4)$

`st_cr = 6` indicates that $\|F(x)\| - \|F(x) - A(x)s\| < \text{eps}(5)$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

<i>handle</i>	Data object of the <code>_TRNSPBC_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
---------------	--------------------------------------------------------------------------------------------------------

Output Parameters

<i>iter</i>	INTEGER. Contains the current number of iterations.
<i>st_cr</i>	INTEGER. Contains the stop criterion. See Description for the parameter values and their meanings.
<i>r1</i>	DOUBLE PRECISION. Contains the initial residual, that is, the value of the function $\ y - f(x)\ $ of the initial x set by the user.
<i>r2</i>	DOUBLE PRECISION. Contains the final residual, that is, the value of the function $\ y - f(x)\ $ of the final x resulting from the algorithm operation.
<i>res</i>	INTEGER. Informs about the task completion.

`res = TR_SUCCESS` means the routine completed the task normally.

dtrnlspbc_delete

Removes the data object required by the TR solver.

Syntax

Fortran:

```
res = dtrnlspbc_delete(handle)
```

C:

```
res = dtrnlspbc_delete(&handle);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine removes the data object needed for the RCI TR solver.

Input Parameters

<code>handle</code>	Data object of the <code>_TRNSPBC_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
---------------------	--------------------------------------------------------------------------------------------------------

Output Parameters

<code>res</code>	<code>INTEGER</code> . Informs about the task completion. <code>res = TR_SUCCESS</code> means the routine completed the task normally.
------------------	-------------------------------------------------------------------------------------------------------------------------------------------

Jacobi Matrix Calculation Routines

This section describes routines that compute the Jacobi matrix using central differences. Jacobi matrix calculation is required to solve nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobi matrix have "Black-Box" interfaces, where users pass the objective function via parameters. Note that in this case the user's objective function must have fixed interface.

Table 14-3 Jacobi Matrix Calculation Routines

Routine Name	Operation
djacobi_init	Initializes the solver.
djacobi_solve	Computes the Jacobi matrix of the function on the basis of RCI using the central difference.
djacobi_delete	Removes data.
djacobi	Computes the Jacobi matrix of the fcn function using the central difference.

djacobi_init

Initializes the solver for Jacobian calculations.

Syntax

Fortran:

```
res = djacobi_init(handle, n, m, x, a, esp)
```

C:

```
res = djacobi_init(&handle, &n, &m, x, a, &eps);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface. The routine initializes the solver.

Input Parameters

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Vector, at which the function is evaluated.
<i>eps</i>	DOUBLE PRECISION. Precision of the Jacobi matrix calculation.

Output Parameters

<i>handle</i>	Data object of the <code>_JACOBIMATRIX_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>a</i>	DOUBLE PRECISION. Array of size (m,n) . Contains the Jacobi matrix of the function.
<i>res</i>	<p>INTEGER. Informs about the task completion.</p> <p><i>res</i> = <code>TR_SUCCESS</code> indicates that the routine completed the task normally.</p> <p><i>res</i> = <code>TR_INVALID_OPTION</code> indicates an error in the input parameters.</p> <p><i>res</i> = <code>TR_OUT_OF_MEMORY</code> indicates a memory error.</p>

djacobi_solve

Computes the Jacobi matrix of the function on the basis of RCI using the central difference.

Syntax

Fortran:

```
res = djacobi_solve(handle, f1, f2, RCI_Request)
```

C:

```
res = djacobi_solve(&handle, f1, f2, &RCI_Request);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface.

The `djacobi_solve` routine computes the Jacobi matrix of the function on the basis of RCI using the central difference.

Input Parameters

handle Data object of the `_JACOBI_MATRIX_HANDLE_t` type in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

f1 DOUBLE PRECISION. Array of size *m*. Contains the updated function values at $X + \text{eps}$.

f2 DOUBLE PRECISION. Array of size *m*. Contains the updated function values at $X - \text{eps}$.

RCI_Request INTEGER. Informs about the task completion. When equal to 0, the task is completed successfully.
RCI_Request= 1 indicates the user should calculate the Jacobian matrix and put the result into *f1*.
RCI_Request= 2 indicates the user should calculate the Jacobian matrix and put the result into *f2*.

res INTEGER. Informs about the task completion.
res = `TR_SUCCESS` indicates that the routine has completed the task normally.

`res = TR_INVALID_OPTION` indicates an error in the input parameters.

djacobi_delete

Removes the data object required by the Jacobian calculation.

Syntax

Fortran:

```
res = djacobi_delete(handle)
```

C:

```
res = djacobi_delete(&handle);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine removes the data object needed for the Jacobi matrix RCI solver.

Input Parameters

<i>handle</i>	Data object of the <code>_JACOBIMATRIX_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
---------------	-------------------------------------------------------------------------------------------------------------

Output Parameters

<i>res</i>	<code>INTEGER</code> . Informs about the task completion. <code>res = TR_SUCCESS</code> means the routine completed the task normally.
------------	-------------------------------------------------------------------------------------------------------------------------------------------

djacobi

Computes the Jacobi matrix of the user's objective function using the cenral difference.

Syntax

Fortran:

```
res = djacobi(fcn, n, m, fjac, x, jac_eps)
```

C:

```
res = djacobi(fcn, &n, &m, fjac, x, &jac_eps);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine computes the Jacobi matrix for function `fcn` using the central difference. This routine has "Black-Box" interface, where the user inputs the objective function via parameters. Note that in this case the user's objective function must have a fixed interface.

Input Parameters

<i>fcn</i>	User-supplied subroutine to evaluate the function that defines the least squares problem. Call <code>fcn(m, n, x, f)</code> with the following parameters: <i>m</i> - INTEGER. Input parameter. Length of <i>f</i> <i>n</i> - INTEGER. Input parameter. Length of <i>x</i> . <i>x</i> - DOUBLE PRECISION. Input parameter. Array of size <i>n</i> . Vector, at which the function is evaluated. The <code>fcn</code> function should not change this parameter. <i>f</i> - DOUBLE PRECISION. Output parameter. Array of size <i>m</i> ; contains the function values at <i>x</i> . Declare <code>fcn</code> as EXTERNAL in the calling program.
<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Vector at which the function is evaluated.
<i>eps</i>	DOUBLE PRECISION. Precision of the Jacobi matrix calculation.

Output Parameters

<i>a</i>	DOUBLE PRECISION. Array of size (m, n) . Contains the Jacobi matrix of the function.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = TR_SUCCESS indicates that the routine has completed the task normally. <i>res</i> = TR_INVALID_OPTION indicates an error in the input parameters. <i>res</i> = TR_OUT_OF_MEMORY indicates a memory error.

    F (4*I-2) = DSQRT(5.D0) * (X(4*I-1) - X(4*I))
    F (4*I-1) = (X(4*I-2) - 2.D0*X(4*I-1))**2
    F (4*I)   = DSQRT(10.D0)*(X(4*I-3) - X(4*I))**2
ENDDO

ENDSUBROUTINE EXTENDET_POWELL

```

Example 14-8. djacobi Usage in C

```

/* compute jacobi matrix
    extendet_powell in:    external objective function
    n               in:    number of function variables
    m               in:    dimension of function value
    fjac            out:    jacobi matrix
    x               in:    solution vector
    jac_eps         in:    jacobi calculation precision */

    if (djacobi (extendet_powell, &n, &m, fjac, x, &jac_eps) != TR_SUCCESS){
/* if function does not complete successfully then print error message */
        printf ("\n#ERROR IN DJACOBI\n");
        return 0;
    }

/* .....*/

/* routine for extendet powell function calculation
    m    in:    dimension of function value
    n    in:    number of function variables
    x    in:    vector for function calculation
    f    out:    function value f(x) */
void extendet_powell (int *m, int *n, double *x, double *f)
{
    int i;

    for (i = 0; i < (*n)/4; i++)
    {

```

14 *Intel® Math Kernel Library*

```
f [4*i] = x [4*i] + 10.0*x [4*i + 1];  
f [4*i + 1] = 2.2360679774*(x [4*i + 2] - x [4*i + 3]);  
f [4*i + 2] = (x [4*i + 1] - 2.0*x [4*i + 2])*(x [4*i + 1] - 2.0*x [4*i + 2]);  
f [4*i + 3] = 3.1622776601*(x [4*i] - x [4*i + 3])*(x [4*i] - x [4*i + 3]);  
}  
return;  
}
```

Support Functions

Intel® MKL support functions are used to:

- retrieve information about the current Intel MKL version
- additionally control the number of threads
- handle errors
- test characters and character strings for equality
- measure user time for a process and elapsed CPU time
- set and measure CPU frequency
- free memory allocated by Intel MKL memory management software

Functions described below are subdivided according to their purpose into the following groups:

[Version Information Functions](#)

[Threading Control Functions](#)

[Error Handling Functions](#)

[Equality Test Functions](#)

[Timing Functions](#)

[Memory Functions](#)

Table 15-1 contains the list of support functions common for Intel MKL.

Table 15-1 Intel MKL Support Functions

Function Name	Operation
Version Information Functions	
<code>MKLGetVersion</code>	Returns information about the active library version.
<code>MKLGetVersionString</code>	Returns information about the library version string.
Threading Control Functions	
<code>mkl_set_num_threads</code>	Suggests the number of threads to use.
<code>mkl_domain_set_num_threads</code>	Suggests the number of threads for a particular function domain.

Function Name	Operation
<code>mkl_set_dynamic</code>	Enables Intel MKL to dynamically change the number of threads.
<code>mkl_get_max_threads</code>	Inquires about the number of threads targeted for parallelism.
<code>mkl_domain_get_max_threads</code>	Inquires about the number of threads targeted for parallelism in different domains.
<code>mkl_get_dynamic</code>	Returns the current value of the <code>MKL_DYNAMIC</code> variable.
Error Handling Functions	
<code>xerbla</code>	Handles error conditions for the BLAS, LAPACK, VML routines.
<code>pxerbla</code>	Handles error conditions for the ScaLAPACK routines.
Equality Test Functions	
<code>lsame</code>	Tests two characters for equality regardless of the case.
<code>lsamen</code>	Tests two character strings for equality regardless of the case.
Timing Functions	
<code>second/dsecnd</code>	Returns user time for a process.
<code>getcpuclocks</code>	Returns full precision elapsed CPU clocks.
<code>getcpufrequency</code>	Returns CPU frequency value in GHz.
<code>setcpufrequency</code>	Sets CPU frequency value in GHz.
Memory Functions	
<code>MKL_FreeBuffers</code>	Frees memory buffers.
<code>MKL_MemStat</code>	Reports an amount of memory utilized by MKL Memory Manager.

Function Name	Operation
<code>MKL_malloc</code>	Allocates the aligned memory buffer.
<code>MKL_free</code>	Frees the aligned memory buffer allocated by <code>MKL_malloc</code> .

Version Information Functions

Intel® MKL provides two methods for extracting information about the library version number:

- extracting a version string using the `MKLGetString` function
- using the `MKLGetVersion` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

MKLGetVersion

Returns information about the active library C version.

Syntax

```
void MKLGetVersion( MKLVersion*  pVersion );
```

Output Parameters

`pVersion` Pointer to the `MKLVersion` structure.

Description

For C interface, this function is declared in `mkl_service.h` header file.

The `MKLGetVersion` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the `pVersion` address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

<code>MajorVersion</code>	is the major number of the current library version.
<code>MinorVersion</code>	is the minor number of the current library version.

BuildNumber	is the update number of the current library version.
ProductStatus	is the status of the current library version. Possible variants could be "Beta", "Product".
Build	is the string that contains the build date and the internal build number.
Processor	is the processor optimization that is targeted for the specific processor. It is not the definition of the processor installed in the system, rather the MKL library detection that is optimal for the processor installed in the system.

MKLGetVersion Usage

```
#include <stdio.h>
#include <stdlib.h>
#include "mkl_blas.h"
#include "mkl_types.h"

int main(void)
{
    MKLVersion Version;
    MKLGetVersion(&Version);

    printf("Major version:          %d\n",Version.MajorVersion);
    printf("Minor version:           %d\n",Version.MinorVersion);
    printf("Update number:             %d\n",Version.BuildNumber);
    printf("Product status:           %s\n",Version.ProductStatus);
    printf("Build:                     %s\n",Version.Build);
    printf("Processor optimization:    %s\n",Version.Processor);
    printf("=====\n");
    printf("\n");
    return 0;
}
```

Output:

Major Version	9
Minor Version	0
Build number	0
Product status	Product
Build	061909.09
Processor optimization	Intel® Xeon® Processor with Intel® 64 architecture

MKLGetVersionString

Gets the library version string.

Syntax

Fortran:

```
call MKLGetVersionString( buf )
```

C:

```
MKLGetVersionString( char* buf, int len );
```

Output Parameters

Name	Type	Description
<i>buf</i>	FORTTRAN: CHARACTER*198	Source string
	C: char*	
<i>len</i>	FORTTRAN: INTEGER	Length of the source string
	C: int	

Description

For C interface, this function is declared in `mkl_service.h` header file.

The function returns a string that contains the library version information.

See example below:

Examples

Fortran:

```
program getversionstring

character*198 buf

call mklgetversionstring(buf)
write(*,'(a)') buf

end
```

C:

```
#include <stdio.h>
#include "mkl_blas.h"

int main(void)
{
    int len=198;
    char buf[198];
    MKLGetVersionString(buf, len);
    printf("%s\n",buf);
    printf("\n");
    return 0;
}
```

Threading Control Functions

Intel® MKL provides optional threading control via service functions that take precedence over setting new environment variables with the same purpose (see *Intel® MKL User's Guide* for details).

These functions enable you to specify the number of threads for Intel MKL independently of the OpenMP* settings and prevailing over OpenMP* equivalents. Although Intel MKL may actually use the number of threads that differs from the one suggested, the controls will also enable you to instruct the library to try using the suggested number in the event of undetectable threading behavior in the application calling the library.

See the following examples of Fortran and C usage:

Fortran Usage

```
call mkl_set_num_threads( foo )
ret = mkl_domain_set_num_threads( num, MKL_BLAS )
call mkl_set_dynamic ( 1 )
num = mkl_get_max_threads()
num = mkl_domain_get_max_threads( MKL_BLAS );
ret = mkl_get_dynamic()
```

C Usage

```
#include "mkl.h" // Mandatory to make these definitions work!
mkl_set_num_threads(num); // Equivalent to omp_set_num_threads( int )
return_code = mkl_domain_set_num_threads( num, MKL_FFT );
mkl_set_dynamic( 1 );
num = mkl_get_max_threads();
num = mkl_domain_get_max_threads( MKL_FFT );
return_code = mkl_get_dynamic();
```

NOTE. Always remember to add `#include "mkl.h"` to use the C usage syntax.

mkl_set_num_threads

Suggests the number of threads to use.

Syntax

Fortran:

```
call mkl_set_num_threads( number )
```

C:

```
void mkl_set_num_threads( int number );
```

Input Parameters

Name	Type	Description
<i>number</i>	FORTTRAN: INTEGER C: int	Number of threads suggested by user

Description

For C interface, this function is declared in `mkl_service.h` header file.

This function allows the user to request independently of OpenMP* how many threads MKL should use. This is just a hint, and it is not guaranteed that this number of threads will be used. The user must enter a positive integer. This routine takes precedence over the `MKL_NUM_THREADS` environment variable .

See *Intel MKL User's Guide* for implementation details.

mkl_domain_set_num_threads

Suggests the number of threads for a particular function domain.

Syntax

Fortran:

```
call integer mkl_domain_set_num_threads( num, mask )
```

C:

```
int mkl_domain_set_num_threads( int  num, int  mask );
```

Input Parameters

Name	Type	Description
<i>num</i>	FORTRAN: INTEGER C: int	Number of threads suggested by user
<i>mask</i>	FORTRAN: INTEGER C: int	Name of the targeted domain

Description

For C interface, this function is declared in `mkl_service.h` header file.

This function allows the user to request different domains of Intel MKL to use different numbers of threads. The currently supported domains are:

- `MKL_BLAS` - BLAS domain
- `MKL_FFT` - FFT domain (excluding cluster FFT)
- `MKL_VML` - vector math library
- `MKL_ALL` - another way to do what `mkl_set_num_threads` does

This is just a hint, and it is not guaranteed that this number of threads will be used. The user must enter a valid domain and a positive integer for the number of threads. This routine has precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

See *Intel MKL User’s Guide* for implementation details.

Return Values

<code>1 (true)</code>	Indicates no error, execution is successful.
<code>0 (false)</code>	Indicates failure, possibly because the inputs were invalid.

mkl_set_dynamic

Enables Intel MKL to dynamically change the number of threads.

Syntax

Fortran:

```
call mkl_set_dynamic( boolean_var )
```

C:

```
void mkl_set_dynamic( int boolean_var );
```

Input Parameters

Name	Type	Description
<i>boolean_var</i>	FORTTRAN: INTEGER C: int	The parameter that determines whether dynamic adjustment of the number of threads is enabled or disabled.

Description

For C interface, this function is declared in `mkl_service.h` header file.

This function indicates whether or not Intel MKL can dynamically change the number of threads. The default for this is `true`, regardless of how the `OMP_DYNAMIC` variable is set. This will also hold precedent over the `OMP_DYNAMIC` variable.

A value of `false` does not guarantee that the user's requested number of threads will be used. But it means that MKL will attempt to use that value. This routine takes precedence over the environment variable `MKL_DYNAMIC`.

Note that if MKL is called from within a parallel region, MKL may not thread unless `MKL_DYNAMIC` is set to `false`, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

mkl_get_max_threads

Inquires about the number of threads targeted for parallelism.

Syntax

Fortran:

```
num = mkl_get_max_threads()
```

C:

```
int mkl_get_max_threads();
```

Description

For C interface, this function is declared in `mkl_service.h` header file.

This function allows the user to inquire independently of OpenMP* how many threads Intel MKL is targeting for parallelism. This is just a hint, and it is not guaranteed that this number of threads will be used.

See *Intel MKL User's Guide* for implementation details.

Return Values

The output is `INTEGER` equal to the number of threads.

mkl_domain_get_max_threads

Inquires about the number of threads targeted for parallelism in different domains.

Syntax

Fortran:

```
call integer mkl_domain_get_max_threads( mask )
```

C:

```
int mkl_domain_get_max_threads( int mask );
```

Input Parameters

Name	Type	Description
<i>mask</i>	FORTTRAN: INTEGER C: int	The name of the targeted domain

Description

For C interface, this function is declared in `mkl_service.h` header file.

This function allows the user of different domains of Intel MKL to inquire what number of threads is being used as a hint. The inquiry does not imply that this is the actual number of threads used. The number may vary depending on the value of the `MKL_DYNAMIC` variable and/or problem size, system resources, etc. But the function returns the value that MKL is targeting for the given domain.

The currently supported domains are:

- `MKL_BLAS` - BLAS domain
- `MKL_FFT` - FFT domain (excluding cluster FFT)
- `MKL_VML` - vector math library
- `MKL_ALL` - another way to do what `mkl_get_max_threads` does.

The user must enter a valid domain.

See *Intel MKL User's Guide* for implementation details.

Return Values

Returns the hint at the number of threads for the given domain.

`mkl_get_dynamic`

Returns current value of `MKL_DYNAMIC` variable.

Syntax

Fortran:

```
ret = mkl_get_dynamic()
```

C:

```
int mkl_get_dynamic();
```

Description

For C interface, this function is declared in `mkl_service.h` header file.

This function returns the current value of the `MKL_DYNAMIC` variable. This variable can be changed by manipulating the `MKL_DYNAMIC` environment variable before the MKL run is launched, or by calling `mkl_set_dynamic()`. Doing the latter has precedence over the former.

The function returns a value of 0 or 1. 1 indicates that `MKL_DYNAMIC` is true. 0 indicates that `MKL_DYNAMIC` is false. This variable indicates whether or not Intel MKL can dynamically change the number of threads. A value of `false` does not guarantee that the user's requested number of threads will be used. But it means that Intel MKL will attempt to use that value. This routine takes precedence over the environment variable `MKL_DYNAMIC`.

Note that if MKL is called from within a parallel region, MKL may not thread unless `MKL_DYNAMIC` is set to `false`, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

Return Values

1	Indicates <code>MKL_DYNAMIC</code> is true.
0	Indicates <code>MKL_DYNAMIC</code> is false.

Error Handling Functions

xerbla

Error handling routine called by BLAS, LAPACK, VML routines.

Syntax

```
call xerbla( sname, info )
```

Input Parameters

sname CHARACTER*6. The name of the routine which called `xerbla`.

info INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface and in `mkl_blas.h` for C interface.

The routine `xerbla` is an error handler for the BLAS, LAPACK, and VML routines. It is called by a BLAS, LAPACK, or VML routine if an input parameter has an invalid value.

A message is printed and execution stops.

Installers may consider modifying the `stop` statement to call system-specific exception-handling facilities.

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
call pxerbla(ictxt, sname, info)
```

Input Parameters

<i>ictxt</i>	(global) INTEGER The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>sname</i>	(global) CHARACTER*6 The name of the routine which called <code>pxerbla</code> .
<i>info</i>	(global) INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine is an error handler for the *ScaLAPACK* routines. It is called by a *ScaLAPACK* routine if an input parameter has an invalid value. A message is printed. Program execution is not terminated. For the *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pserbla`.

Control returns to the higher-level calling routine, and it is left to the user to determine how the program should proceed. However, in the specialized low-level *ScaLAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pserbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *info* on return from a *ScaLAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Equality Test Functions

lsame

Tests two characters for equality regardless of the case.

Syntax

```
val = lsame( ca, cb )
```

Input Parameters

ca, cb CHARACTER*1. Specify the single characters to be compared.

Output Parameters

val LOGICAL. Result of the comparison.

Description

This logical function returns `.TRUE.` if *ca* is the same letter as *cb* regardless of the case.

lsamen

Tests two character strings for equality regardless of the case.

Syntax

```
val = lsamen( n, ca, cb )
```

Input Parameters

<i>n</i>	INTEGER. The number of characters in <i>ca</i> and <i>cb</i> to be compared.
<i>ca, cb</i>	CHARACTER*(*). Specify two character strings of length at least <i>n</i> to be compared. Only the first <i>n</i> characters of each string will be accessed.

Output Parameters

<i>val</i>	LOGICAL. Result of the comparison.
------------	------------------------------------

Description

This logical function tests if the first *n* letters of the string *ca* are the same as the first *n* letters of *cb*, regardless of case. The function `lsamen` returns `.TRUE.` if *ca* and *cb* are equivalent except for the case and `.FALSE.` otherwise. `lsamen` also returns `.FALSE.` if `len(ca)` or `len(cb)` is less than *n*.

Timing Functions

second/dsecnd

Returns elapsed CPU time in seconds.

Syntax

```
val = second()
val = dsecnd()
```

Output Parameters

`val` REAL for `second`
 DOUBLE PRECISION for `dsecnd`
 Elapsed CPU time in seconds.

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The `second/dsecnd` functions return the elapsed CPU time in seconds. These versions get the time from the elapsed CPU clocks divided by CPU frequency. The difference is that `dsecnd` returns the result with double precision.

The functions should be applied in pairs: the first time, before a routine to be measured, and the second time - after the measurement. The difference between the returned values is the time spent in the routine. The usage of `second` is discouraged for measuring short time intervals because the single precision format is not capable of holding sufficient timer precision.

getcpuclocks

Returns full precision elapsed CPU clocks.

Syntax

`getcpuclocks(clocks)`

Output Parameters

`clocks` INTEGER*8. Elapsed CPU clocks.

Description

For C interface, this function is declared in `mk1_service.h` header file.

The `getcpuclocks` subroutine returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `getcpuclocks` subroutine is also applied in pairs like `second/dsecnd`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

getcpufrequency

Returns CPU frequency value in GHz.

Syntax

```
val = getcpufrequency()
```

Output Parameters

val DOUBLE PRECISION. CPU frequency value in GHz.

Description

For C interface, this function is declared in `mkl_service.h` header file.

The function `getcpufrequency` returns the CPU frequency in GHz. This value is used by `second`/`dsecnd` functions while converting CPU clocks into seconds.

Obtaining a frequency may take some time when `second`/`dsecnd`/`getcpufrequency` is called for the first time. To avoid it, call `setcpufrequency` before setting the exact CPU frequency if it is known in advance.

setcpufrequency

Sets CPU frequency value in GHz.

Syntax

```
setcpufrequency( freq )
```

Output Parameters

freq DOUBLE PRECISION. CPU frequency value in GHz.

Description

The `setcpufrequency` function sets the CPU frequency in GHz, used then by `second`/`dsecnd` functions while converting CPU clocks into seconds. Setting the exact CPU frequency is useful to bypass obtaining a frequency by `getcpufrequency`.

Initially, CPU frequency value is unset. The CPU frequency value can be set only by `setcpufrequency` call, or during the first call of `getcpufrequency`, if `setcpufrequency` has not been called before. Calling `setcpufrequency` with a special parameter `freq = -1.0` forces the CPU frequency value be unset.

Note that the CPU frequency of your machine is not actually changed when the `setcpufrequency` subroutine is called.

Memory Functions

This section describes the Intel MKL memory support functions. See the *Intel® MKL User's Guide* for details of the Intel MKL memory management.

MKL_FreeBuffers

Frees memory buffers.

Syntax

```
void MKL_FreeBuffers(void)
```

Description

For C interface, this function is declared in `mkl_service.h` header file.

The `MKL_FreeBuffers` function frees the memory allocated by the Intel MKL Memory Manager. The Memory Manager allocates new buffers if no free buffers are currently available. Call `MKL_FreeBuffers()` to free all memory buffers and to avoid memory leaking on completion of work with the Intel MKL functions, that is, after the last call of an Intel MKL function from your application.

See *Intel® MKL User's Guide* for details.

MKL_FreeBuffers Usage with FFT Functions

```
-----  
DFTI_DESCRIPTOR *hand1, *hand2;  
void MKL_FreeBuffers(void);  
  
. . . . .  
/* Using MKL FFT */  
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);  
Status = DftiCommitDescriptor(hand1);  
Status = DftiComputeForward(hand1, s_array1);  
  
. . . . .  
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);  
Status = DftiCommitDescriptor(hand2);  
  
. . . . .  
Status = DftiFreeDescriptor(&hand1);  
/* Do not call MKL_FreeBuffers() here as the hand2 descriptor will be destroyed! */  
  
. . . . .  
Status = DftiComputeBackward(hand2, s_array2));  
Status = DftiFreeDescriptor(&hand2);  
/* Here user finishes the MKL FFT usage */  
/* Memory leak will be triggered by any memory control tool */  
/* Use MKL_FreeBuffers() to avoid memory leaking */  
MKL_FreeBuffers();  
-----
```

If the memory space is sufficient, use `MKL_FreeBuffers` after the last call of the MKL functions. Otherwise, a drop in performance can occur due to reallocation of buffers for the subsequent MKL functions.

WARNING. For FFT calls, do not use `MKL_FreeBuffers` between `DftiCreateDescriptor(hand)` and `DftiFreeDescriptor(&hand)`.

MKL_MemStat

Reports amount of memory utilized by MKL Memory Manager.

Syntax

Fortran:

```
AllocatedBytes = MKL_MEMSTAT( AllocatedBuffers )
```

C:

```
AllocatedBytes = MKL_MemStat ( int* AllocatedBuffers );
```

Output Parameters

Name	Type	Description
<i>AllocatedBytes</i>	FORTTRAN: INTEGER*8 C: MKL_INT64	Amount of allocated bytes
<i>AllocatedBuffers</i>	FORTTRAN: INTEGER*4, C: int*	Number of allocated buffers

Description

For C interface, this function is declared in `mkl_service.h` header file.

The function returns the amount of the allocated memory in the *AllocatedBuffers* buffers. If there are no allocated buffers at the moment, the function returns 0. Call the `MKL_MemStat()` function to check the Intel MKL memory status.

Note that after calling `MKL_FreeBuffers()` there should not be any allocated buffers.

See [Example “MKL_malloc\(\), MKL_free\(\), MKL_MemStat\(\) Usage”](#).

MKL_malloc

Allocates the aligned memory buffer.

Syntax

Fortran:

```
ptr = MKL_MALLOC ( size, alignment )
```

C:

```
void* MKL_malloc ( size_t size , int alignment );
```

Input Parameters

Name	Type	Description
<i>size</i>	FORTTRAN: INTEGER C: size_t	Size of the buffer to be allocated
<i>alignment</i>	FORTTRAN: INTEGER C: int	Alignment of the allocated buffer

Output Parameters

Name	Type	Description
<i>ptr</i>	FORTTRAN: POINTER C: void*	Pointer to the allocated buffer

Description

For C interface, this function is declared in `mkl_service.h` header file.

The function allocates a *size*-bytes buffer, aligned on the *alignment* boundary, and returns a pointer to this buffer.

The function returns `NULL` if *size* < 1. If alignment is not power of 2, the alignment 32 is used.

See [Example “MKL_malloc\(\), MKL_free\(\), MKL_MemStat\(\) Usage”](#).

MKL_free

Frees the aligned memory buffer allocated by MKL_malloc.

Syntax

Fortran:

```
CALL MKL_FREE ( ptr )
```

C:

```
void* MKL_free ( void* ptr );
```

Input Parameters

Name	Type	Description
<i>ptr</i>	FORTTRAN: POINTER C: void*	Pointer to the buffer to be freed

Description

For C interface, this function is declared in `mkl_service.h` header file.

The function frees the buffer pointed by *ptr* and allocated by `MKL_malloc()`.

See [Example “MKL_malloc\(\), MKL_free\(\), MKL_MemStat\(\) Usage”](#).

Examples of MKL_malloc(), MKL_free(), MKL_MemStat() Usage

Usage Example in Fortran

```

PROGRAM FOO

REAL*8      A,B,C
POINTER      (A_PTR,A(1)), (B_PTR,B(1)), (C_PTR,C(1))
INTEGER      N, I
REAL*8      ALPHA, BETA
INTEGER*8    ALLOCATED_BYTES
INTEGER*4    ALLOCATED_BUFFERS

#ifdef _SYSTEM_BITS32
    INTEGER*4 MKL_MALLOC
    INTEGER*4 ALLOC_SIZE
#else
    INTEGER*8 MKL_MALLOC
    INTEGER*8 ALLOC_SIZE
#endif

INTEGER      MKL_MEMSTAT
EXTERNAL     MKL_MALLOC, MKL_FREE, MKL_MEMSTAT

ALPHA = 1.1; BETA = -1.2

N = 1000

ALLOC_SIZE = 8*N*N
A_PTR = MKL_MALLOC(ALLOC_SIZE,128)
B_PTR = MKL_MALLOC(ALLOC_SIZE,128)

```

```
C_PTR = MKL_MALLOC(ALLOC_SIZE,128)
DO I=1,N*N
    A(1) = I
    B(1) = -I
    C(1) = 0.0
END DO

CALL DGEMM('N','N',N,N,N,ALPHA,A,N,B,N,BETA,C,N);

ALLOCATED_BYTES = MKL_MEMSTAT(ALLOCATED_BUFFERS)
PRINT *, 'DGEMM uses ',ALLOCATED_BYTES,' bytes in ',
$  ALLOCATED_BUFFERS,' buffers '

CALL MKL_FREEBUFFERS

ALLOCATED_BYTES = MKL_MEMSTAT(ALLOCATED_BUFFERS)
IF (ALLOCATED_BYTES > 0) THEN
    PRINT *, 'MKL MEMORY LEAK!'
    PRINT *, 'AFTER MKL_FREEBUFFERS there are ',
$  ALLOCATED_BYTES,' bytes in ',
$  ALLOCATED_BUFFERS,' buffers'
END IF

CALL MKL_FREE(A_PTR)
CALL MKL_FREE(B_PTR)
CALL MKL_FREE(C_PTR)

STOP
```

END

Usage Example in C

```
#include <stdio.h>

#include <mkl.h>

int main(void) {
    double *a, *b, *c;

    int n, i;

    double alpha, beta;

    MKL_INT64 AllocatedBytes;
    int N_AllocatedBuffers;

    alpha = 1.1; beta = -1.2;
    n = 1000;
    a = (double*)MKL_malloc(n*n*sizeof(double),128);
    b = (double*)MKL_malloc(n*n*sizeof(double),128);
    c = (double*)MKL_malloc(n*n*sizeof(double),128);
    for (i=0;i<(NN*NN);i++) {
        a[i] = (double)(i+1);
        b[i] = (double)(-i-1);
        c[i] = 0.0;
    }

    dgemm('N','N', &n, &n, &n, &alpha, a, &n, b, &n, &beta, c, &n);

    AllocatedBytes = MKL_MemStat(&N_AllocatedBuffers);
    printf('\nDGEMM uses %ld bytes in %d buffers', (long)AllocatedBytes, N_AllocatedBuffers);

    MKL_FreeBuffers();
}
```

```
AllocatedBytes = MKL_MemStat(&N_AllocatedBuffers);  
if (AllocatedBytes > 0) {  
    printf("\nMKL memory leak!");  
    printf("\nAfter MKL_FreeBuffers there are %ld bytes in %d buffers",  
        (long)AllocatedBytes, N_AllocatedBuffers);  
}  
  
MKL_free(a);  
MKL_free(b);  
MKL_free(c);  
  
return 0;  
}
```

BLACS Routines

This chapter describes the Intel® Math Kernel Library implementation of FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux* and Windows* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of m rows and n columns, with a leading dimension, lda , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

m	(input) INTEGER. The number of matrix rows to be operated on.
n	(input) INTEGER. The number of matrix columns to be operated on.
a	(input/output) TYPE (depends on routine), array of dimension (lda, n) . A pointer to the beginning of the (sub)array to be sent.

lda (input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by m , n , and lda , as above, but they have two additional parameters as well. These parameters are:

uplo (input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.

diag (input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

Figure 16-1 Trapezoidal Arrays Shapes

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (`max/min/sum`) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the `max/min` comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex.

Table 16-1 BLACS Combines

Routine name	Results of operation
<code>?gamx2d</code>	Entries of result matrix will have the value of the greatest absolute value found in that position.
<code>?gamn2d</code>	Entries of result matrix will have the value of the smallest absolute value found in that position.
<code>?gsum2d</code>	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be compared with to produce the maximum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.

<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (lda, n). Matrix to be compared with to produce the minimum.
<i>lda</i>	INTEGER. The leading dimension of the matrix A, that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER.

If *rcflag* = -1, the arrays *ra* and *ca* are not referenced and need not exist. Otherwise, *rcflag* indicates the leading dimension of these arrays, and so must be $\geq m$.

rdest

INTEGER.

The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

cdest

INTEGER.

The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a

TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

ra

INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* \times *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

ca

INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* \times *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (lda, n). Matrix to be added to produce the sum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER.

The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the

receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
IF (IAM .EQ. 0) THEN
    SEND TO PROCESS 1
    RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
    SEND TO PROCESS 0
    RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
sd	Send. One process sends to another.
rv	Receive. One process receives from another.

Table 16-2 BLACS Point To Point Communication

Routine name	Operation performed
<code>?gesd2d</code> <code>?trsd2d</code>	Take the indicated matrix and send it to the destination process.
<code>?gerv2d</code> <code>?trrv2d</code>	Receive a message from the process into the matrix.

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector x , which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)
```

```
IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
```

```
    CALL DGESD2D(5, 1, X, 5, 1, 0)
```

```
    CALL DGERV2D(5, 1, X, 5, 1, 0)
```

```
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
```

```
    CALL DGESD2D(5, 1, X, 5, 0, 0)
```

```
    CALL DGERV2D(5, 1, X, 5, 0, 0)
```

```
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

```
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

```
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

```
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

```
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER.

The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

See Also

- [BLACS Point To Point Communication](#)
- [BLACS Routines Usage Example](#)

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrdsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strdsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call dtrdsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrdsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrdsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER. The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	------------------------------------------------------------------------

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

See Also

- [BLACS Point To Point Communication](#)
- [BLACS Routines Usage Example](#)

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER. The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	------------------------------------------------------------------------

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

BLACS Broadcast Routines

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

`i` integer

s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
bs	Broadcast/send. A process begins the broadcast of data within a scope.
br	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

Table 16-3 BLACS Broadcast Routines

Routine name	Operation performed
<code>?gebs2d</code>	Start a broadcast along a scope.
<code>?trbs2d</code>	
<code>?gebr2d</code>	Receive and participate in a broadcast along a scope.
<code>?trbr2d</code>	

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.

<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

- [BLACS Broadcast Routines](#)
- [BLACS Routines Usage Example](#)

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.

uplo, diag, m,
n, a, lda Describe the matrix to be sent. See [Matrix Shapes](#) for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.

csrc INTEGER.
The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

- [BLACS Broadcast Routines](#)
- [BLACS Routines Usage Example](#)

?trbr2d

Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.
scope CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.

<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	------------------------------------------------------------------------

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

BLACS Support Routines

The support routines perform distinct tasks that can be used for:

[Initialization](#)

[Destruction](#)

[Information Purposes](#)

[Miscellaneous Tasks.](#)

Initialization Routines

This section describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

Table 16-4 BLACS Initialization Routines

Routine name	Operation performed
<code>blacs_pinfo</code>	Returns the number of processes available for use.
<code>blacs_setup</code>	Allocates virtual machine and spawns processes.
<code>blacs_get</code>	Gets values that BLACS use for internal defaults.
<code>blacs_set</code>	Sets values that BLACS use for internal defaults.
<code>blacs_gridinit</code>	Assigns available processes into BLACS process grid.
<code>blacs_gridmap</code>	Maps available processes into BLACS process grid.

blacs_pinfo

Returns the number of processes available for use.

Syntax

```
call blacs_pinfo( mypnum, nprocs )
```

Output Parameters

mypnum INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

nprocs INTEGER. The number of processes available for BLACS use.

Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, $nprocs * nprows * npcpls \leq nprocs$. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to `BLACS_SETUP`, this routine returns the correct values for *mypnum* and *nprocs*.

See Also

- [Initialization Routines](#)
- [BLACS Routines Usage Example](#)

blacs_setup

Allocates virtual machine and spawns processes.

Syntax

```
call blacs_setup( mypnum, nprocs )
```

Input Parameters

nprocs INTEGER. On the process spawned from the keyboard rather than from `pvmspawn`, this parameter indicates the number of processes to create when building the virtual machine.

Output Parameters

mypnum INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

nprocs INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to `blacs_pinfo`. The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

`blacs_setup` is used to allocate the virtual machine and spawn off processes. It reads in a file called `blacs_setup.dat`, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (`PvmTaskDefault`), 4 (`PvmTaskDebug`), 8 (`PvmTaskTrace`), and 12 (`PvmTaskDebug + PvmTaskTrace`). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to `blacs_pinfo` informs you that the virtual machine has not been set up, and a call to `blacs_setup` then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file `blacs_setup.dat` does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

See Also

- [Initialization Routines](#)
- [BLACS Routines Usage Example](#)

blacs_get

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( icontxt, what, val )
```

Input Parameters

<i>icontxt</i>	INTEGER. On values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	<p>INTEGER. Indicates what BLACS internal(s) should be returned in <i>val</i>. Present options are:</p> <ul style="list-style-type: none"> • <i>what</i> = 0 : Handle indicating default system context • <i>what</i> = 1 : The BLACS message ID range • <i>what</i> = 2 : The BLACS debug level the library was compiled with • <i>what</i> = 10 : Handle indicating the system context used to define the BLACS context whose handle is <i>icontxt</i> • <i>what</i> = 11 : Number of rings multiring topology is presently using • <i>what</i> = 12 : Number of branches general tree topology is presently using.

Output Parameters

val INTEGER. The value of the BLACS internal.

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into `blacs_gridinit` or `blacs_gridmap`.

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use `blacs_get` to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

`blacs_get` returns information on three quantities that are tied to an individual BLACS context, which is passed in as *icontxt*. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for `TOP = 'M'` (multiring broadcast)
- The number of branches for `TOP = 'T'` (general tree broadcast/general tree gather).

See Also

- Initialization Routines
- BLACS Routines Usage Example

blacs_set

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( icontxt, what, val )
```

Input Parameters

icontxt INTEGER. For values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

<i>what</i>	<p>INTEGER. Indicates what BLACS internal(s) should be set. Present values are:</p> <ul style="list-style-type: none"> • 1 = The BLACS message ID range • 11 = Number of rings for multiring topology to use • 12 = Number of branches for general tree topology to use.
<i>val</i>	<p>INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <i>what</i> values, as discussed in Description below.</p>

Description

This routine sets the BLACS internal defaults depending on *what* values:

<i>what</i> = 1	<p>Setting the BLACS message ID range.</p> <p>If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to <code>blacs_gridinit</code> or <code>blacs_gridmap</code>. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter <i>icontxt</i> is ignored, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (2)</p> <p>VAL(1) : The smallest message ID (also called message type or message tag) the BLACS should use.</p> <p>VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.</p>
<i>what</i> = 11	<p>Set number of rings for TOP = 'M' (multiring broadcast). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of rings for multiring topology to use.</p>
<i>what</i> = 12	<p>Set number of rings for TOP = 'T' (general tree broadcast/general tree gather). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of branches for general tree topology to use.</p>

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

```
call blacs_gridinit( icontxt, order, nprow, npcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<i>order</i>	CHARACTER*1. Indicates how to map processes to BLACS grid. Options are: <ul style="list-style-type: none"> • 'R' : Use row-major natural ordering • 'C' : Use column-major natural ordering • ELSE : Use row-major natural ordering
<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.
<i>npcol</i>	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

<i>icontxt</i>	INTEGER. Integer handle to the created BLACS context.
----------------	-------------------------------------------------------

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridmap`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine creates a simple `nprow × npcol` process grid. This process grid uses the first `nprow * npcol` processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

- `blacs_get` Gets values that BLACS use for internal defaults.
- `blacs_gridmap` Maps available processes into BLACS process grid.
- `blacs_setup` Allocates virtual machine and spawns processes.

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( icontxt, usermap, ldumap, nprow, npcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<i>usermap</i>	INTEGER. Array, dimension (<i>ldumap</i> , <i>npcol</i>), indicating the process-to-grid mapping.
<i>ldumap</i>	INTEGER. Leading dimension of the 2D array <i>usermap</i> . <i>ldumap</i> ≥ <i>nprow</i> .
<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.

npcol INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i,j)` holds the process number of the process to be placed in `{i, j}` of the process grid. On most distributed systems, this process number is a machine defined number between 0 ... `nprow-1`. For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a `gridmap` where the first `nprow * npcol` processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

Table 16-5 BLACS Destruction Routines

Routine name	Operation performed
<code>blacs_freebuff</code>	Frees BLACS buffer.
<code>blacs_gridexit</code>	Frees a BLACS context.
<code>blacs_abort</code>	Aborts all processes.
<code>blacs_exit</code>	Frees all BLACS contexts and releases all allocated memory.

`blacs_freebuff`

Frees BLACS buffer.

Syntax

```
call blacs_freebuff( icontxt, wait )
```

Input Parameters

<code>icontxt</code>	INTEGER. Integer handle that indicates the BLACS context.
<code>wait</code>	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The `wait` parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If `wait = 0`, the BLACS free any buffers that can be freed without waiting. If `wait` is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

blacs_gridexit

Frees a BLACS context.

Syntax

```
call blacs_gridexit( ictxt )
```

Input Parameters

<code>ictxt</code>	INTEGER. Integer handle that indicates the BLACS context to be freed.
--------------------	-----------------------------------------------------------------------

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

blacs_abort

Aborts all processes.

Syntax

```
call blacs_abort( ictxt, errornum )
```

Input Parameters

<code>ictxt</code>	INTEGER. Integer handle that indicates the BLACS context to be aborted.
--------------------	-------------------------------------------------------------------------

errornum

INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

blacs_exit

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

continue

INTEGER. Flag indicating whether message passing continues after the BLACS are done. If *continue* is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM `send/recvs` will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

Informational Routines

This section describes BLACS routines that return information involving the process grid.

Table 16-6 BLACS Informational Routines

Routine name	Operation performed
<code>blacs_gridinfo</code>	Returns information on the current grid.
<code>blacs_pnum</code>	Returns the system process number of the process in the process grid.
<code>blacs_pcoord</code>	Returns the row and column coordinates in the process grid.

`blacs_gridinfo`

Returns information on the current grid.

Syntax

call `blacs_gridinfo(ictxt, nprow, npcol, myprow, mypcol)`

Input Parameters

`ictxt` INTEGER. Integer handle that indicates the context.

Output Parameters

`nprow` INTEGER. Number of process rows in the current process grid.

`npcol` INTEGER. Number of process columns in the current process grid.

`myprow` INTEGER. Row coordinate of the calling process in the process grid.

`mypcol` INTEGER. Column coordinate of the calling process in the process grid.

Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

See Also

- [Informational Routines](#)
- [BLACS Routines Usage Example](#)

blacs_pnum

Returns the system process number of the process in the process grid.

Syntax

```
call blacs_pnum( ictxt, prow, pcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.
<i>prow</i>	INTEGER. Row coordinate of the process the system process number of which is to be determined.
<i>pcol</i>	INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {*PROW*, *PCOL*} in the process grid.

See Also

- [Informational Routines](#)
- [BLACS Routines Usage Example](#)

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( ictxt, pnun, prow, pcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>pnum</i>	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a <code>tid</code> for PVM.

Output Parameters

<i>pro</i>	INTEGER. Row coordinates of the <i>pnum</i> process in the BLACS grid.
<i>pcol</i>	INTEGER. Column coordinates of the <i>pnum</i> process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

Miscellaneous Routines

This section describes `blacs_barrier` routine.

Table 16-7 BLACS Informational Routines

Routine name	Operation performed
<code>blacs_barrier</code>	Holds up execution of all processes within the indicated scope until they have all called the routine.

`blacs_barrier`

Holds up execution of all processes within the indicated scope.

Syntax

call `blacs_barrier(icontxt, scope)`

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Parameter that indicates whether a process row (<i>scope</i> ='R'), column ('C'), or entire grid ('A') will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Example 16-1. BLACS Usage. Hello World

The following routine takes the available processes, forms them into a process grid, and then has each process check in with the process at {0,0} in the process grid.

```
PROGRAM HELLO
*

Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $Ax = b$, where A is an m -by- n matrix, x is the n element column vector and b is the m element column vector. The matrix A is usually referred to as the coefficient matrix, and the vectors x and b are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in section [Sparse Linear Systems](#) that follows.

Sparse Linear Systems

In many real-life applications, most of the elements in A are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $Ax = b$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix A . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently for the right applications, iterative solvers can be very efficient.

Direct Solvers, on the other hand, often factor the matrix A into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array A .

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row i and column j in matrix A is denoted by $a(i, j)$. For example, a 3 by 4 matrix A , is written as follows:

$$A = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix A with the property that $a(i, j) = a(j, i)$, is called a symmetric matrix. A complex matrix A with the property that $a(i, j) = \text{conj}(a(j, i))$, is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix A is the matrix obtained by “flipping” the elements of the array about its diagonal. That is, we exchange the elements $a(i, j)$ and $a(j, i)$. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix A are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix A is said to be positive definite if the vector-matrix product $x^T A x$ is greater than zero for all non-zero vectors x . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A , the result of the matrix product PA is identical to A except for interchanging the rows of A . For a square matrix, it can be shown that if PA is a permutation of the rows of A , then AP^T is the same permutation of the columns of A . Additionally, it can be shown that the inverse of P is P^T .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i -th row of a matrix to the j -th row, then the i -th element of the permutation vector is j .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U , such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUx &= b \\ \Rightarrow (Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A , that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H . Consequently, a solver can increase its efficiency by only storing L , and one-half of A , and not computing U . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L , D , and half of A and we need not compute U . However, the backward solve phases must be amended to solving $L^T x = D^{-1} y$ rather than $L^T x = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is the symmetric positive definite sparse matrix defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & 1 & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & \frac{5}{8} & * & * \\ 3 & * & * & * & 16 \end{bmatrix} b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of A . The Cholesky factorization of A is: $A = LL^T$, where L is the following:

$$L = \begin{bmatrix} 3 & * & * & * & * \\ \frac{1}{2} & \frac{1}{2} & * & * & * \\ 2 & -2 & 2 & * & * \\ \frac{1}{4} & \frac{1}{-4} & \frac{1}{-2} & \frac{1}{2} & * \\ 1 & -1 & -2 & -3 & 1 \end{bmatrix}$$

Notice that even though the matrix A is relatively sparse, the lower triangular matrix L has no zeros below the diagonal. If we computed L and then used it for the forward and backward solve phase, we would do as much computation as if A had been dense.

The situation of L having non-zeros in places where A has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of A in such a way as to reduce the fill-in when computing L . By doing this, the solver would only need to compute the non-zero entries in L . Toward this end, consider permuting the rows and columns of A . As described in [Matrix Fundamentals](#) section, the permutations of the rows of A can be represented as a permutation matrix, P . The result of permuting the rows is the product of P and A . Suppose, in the above example, we swap the first and fifth row of A , then swap the first and fifth columns of A , and call the resulting matrix B . Mathematically, we can express the process of permuting the rows and columns of A to get B as $B = PAP^T$. After permuting the rows and columns of A , we see that B is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since B is obtained from A by simply switching rows and columns, the numbers of non-zero entries in A and B are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with B is much smaller than the fill-in associated with A . Consequently, the storage and computation time needed to factor B is much smaller than to factor A . Based on this, we see that an efficient sparse solver needs to find permutation P of the matrix A , which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of B to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general LU decomposition. Specifically, let P be a permutation matrix, $B = PAP^T$ and suppose that B can be factored as $B = LU$. Then

$$Ax = b$$

$$\Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^TP)x = Pb$$

$$\Rightarrow (PAP^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an LU factorization for B , we can solve the original system of equations by a three step process:

- 1.** Solve $Ly = Pb$.
- 2.** Solve $Uz = y$.
- 3.** Set $x = P^Tz$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives: $y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{3}}{12}$.

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since we are using a Cholesky factorization, $L^T z = y$.

$$\begin{bmatrix} 4 & * & * & * & \frac{3}{4} \\ * & \frac{1}{\sqrt{2}} & * & * & \frac{3}{\sqrt{2}} \\ * & * & 2(\sqrt{3}) & * & \sqrt{3} \\ * & * & * & \frac{\sqrt{10}}{4} & \frac{3}{\sqrt{10}} \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{3}}{12} \end{bmatrix}$$

This gives $z = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}$.

The third and final step is to set $x = P^T z$. This gives $X^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}$.

Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

The storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

<i>values</i>	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column that contains the <i>i</i> -th element in the <i>values</i> array.
<i>rowIndex</i>	Element <i>j</i> of the integer array <i>rowIndex</i> gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the `rowIndex` array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the I -th row is equal to the difference of `rowIndex(I)` and `rowIndex(I+1)`.

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of `rowIndex`. Its value is equal to the number of non-zero elements plus one. This makes the total length of the `rowIndex` array one larger than the number of rows in the matrix.

NOTE. The Intel MKL sparse storage scheme for the direct sparse solvers uses the Fortran programming language convention of starting array indices at 1.

Consider the symmetric matrix A :

$$A = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{bmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix A are as follows:

Table A-1 Storage Arrays for a Symmetric Matrix

<code>values</code>	=	(1	-1	-3	5	4	6	4	7	-5)
<code>columns</code>	=	(1	2	4	2	3	4	5	4	5)
<code>rowIndex</code>	=	(1	4	5	8	9	10)			

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix B :

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

The matrix *B* has 13 non-zero elements, and all of them are stored as follows:

Table A-2 Storage Arrays for a Non-Symmetric Matrix

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)	
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)	
<i>rowIndex</i>	=	(1	4	6	9	12	14)								

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if $a(j, i)$ is not zero if and only if $a(i, j)$ is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value is equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{bmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Table A-3 Storage Arrays for a Symmetrically Structured Matrix

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
<i>columns</i>	=	(1	2	4	1	2	5	3	4	5	1	3	4	2	3	5)

rowIndex

=

(147101316)

Storage Format Restrictions

- The storage format for the sparse solver must conform to two important restrictions:
- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
 - no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

This section describes in detail the sparse matrix storage formats supported in the current version of the Intel MKL Sparse BLAS Level 2 and Level 3.

CSR Format

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the row-major storage mapping described above.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j) - pointerB(1)+1</i> .
<i>pointerE</i>	An integer array that contains row indices, such that <i>pointerE(j)-pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a row <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*.The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

NOTE. Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix B

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

can be represented in the CSR format as:

Table A-4 Storage Arrays for a Matrix in CSR Format

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
pointerB	=	(1	4	6	9	12)								
pointerE	=	(4	6	9	12	14)								
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
pointerB	=	(0	3	5	8	11)								
pointerE	=	(3	5	8	11	13)								

This storage format is used in the NIST Sparse BLAS library [[Rem05](#)].

Note that the storage format accepted for the direct sparse solvers and described above (see [Storage Formats for the Direct Sparse Solvers](#)) is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix B can be represented in this format (referred to as the 3-array variation of the CSR format) as:

Table A-5 Storage Arrays for a Matrix in CSR Format (3-Array Variation)

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
rowIndex	=	(1	4	6	9	12	14)							
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
rowIndex	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row J goes just after the set of non-zero elements in the row $J-1$.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

Comparing the array *rowIndex* from the Table A-2 with the arrays *pointerB* and *pointerE* from the Table A-4 it is easy to see that

```
pointerB(I) = rowIndex(I) for I=1, ..5;
pointerE(I) = rowIndex(I+1) for I=1, ..5.
```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
Subroutine name_routine(... , values, columns, pointerB, pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
call name_routine(... , values, columns, rowIndex, rowindex(2), ...).
```

CSC Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the column-major storage mapping.
<i>rows</i>	Element <i>I</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j) - pointerB(1)+1</i> .
<i>pointerE</i>	An integer array that contains column indices, such that <i>pointerE(j)-pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a column <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

NOTE. Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

The above matrix *B* can be represented in the CSC format as:

Table A-6 Storage Arrays for a Matrix in CSC Format

one-based indexing

<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(1	2	4	1	2	5	3	4	1	3	4	2	5)
<i>pointerB</i>	=	(1	4	7	9	12)								
<i>pointerE</i>	=	(4	7	9	12	14)								

zero-based indexing

<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
---------------	---	----	----	----	----	---	---	---	---	----	---	---	---	-----

<i>rows</i>	=	(0	1	3	0	1	4	2	3	0	2	3	1	4)
<i>pointerB</i>	=	(0	3	6	8	11)								
<i>pointerE</i>	=	(3	6	8	11	13)								

Coordinate Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> in any order.
<i>rows</i>	Element <i>I</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array .

NOTE. Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{bmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{bmatrix}$$

can be represented in the coordinate format as follows:

Table A-7 Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
columns	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)
columns	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

Diagonal Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

<i>values</i>	A real or complex two-dimensional array is dimensioned as <i>lval</i> by <i>ndiag</i> . Each column of it contains the non-zero elements of certain diagonal of <i>A</i> . The key point of the storage is that each element in <i>values</i> retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of <i>distance(I)</i> is the number of elements to be padded for diagonal <i>I</i> .
<i>distance</i>	An integer array with dimension <i>ndiag</i> . Element <i>I</i> of the array <i>distance</i> is the distance between <i>I</i> -diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

$$\begin{aligned}
 \text{distance} &= (-3 \quad -1 \quad 0 \quad 1 \quad 2) \\
 \text{values} &= \begin{bmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{bmatrix}
 \end{aligned}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Skyline Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

<i>values</i>	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
<i>pointers</i>	An integer array with dimension $(m+1)$, where m is the number of rows for lower triangle (columns for the upper triangle). $\text{pointers}(I) - \text{pointers}(1) + 1$ gives the index of element in <i>values</i> that is first non-zero element in row (column) I . The value of $\text{pointers}(m+1)$ is set to $\text{nnz} + \text{pointers}(1)$, where nnz is the number of elements in the array <i>values</i> .

For example, the low triangle of the matrix *C* given above can be stored as follows:

```
values = ( 1  -2  5  4  -4  0  2  7  8  0  0  -5 )
```

```
pointers = ( 1  2  4  5  9  13 )
```

and the upper triangle of this matrix *C* can be stored as follows:

```
values = ( 1  -1  5  -3  0  4  6  7  4  0  -5 )
```

```
pointers = ( 1  2  4  7  9  12 )
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format does not support general matrices.

BSR Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>I</i> -th non-zero block.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.
<i>pointerE</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row <i>j</i> of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE. Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix D

$$D = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 2 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix D can be represented as a 3x3 block matrix E with the following structure:

$$E = \begin{bmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 1 \end{bmatrix}, P = \begin{bmatrix} 4 & 3 \\ 0 & 0 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The matrix D can be represented in the BSR format as follows:

one-based indexing

`values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)`

`columns = (1 2 2 2 3)`

`pointerB = (1 3 4)`

`pointerE = (3 4 6)`

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
columns = (0  1  1  1  2)
pointerB = (0  2  3)
pointerE = (2  3  5)
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Intel MKL supports the variation of the BSR format that is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>I</i> -th non-zero block.
<i>rowIndex</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *I*-th row is equal to the difference of *rowIndex(I)* and *rowIndex(I+1)*.

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zeros blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0)
columns = (1  2  2  2  3)
rowIndex = (1  3  4  6)
```

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
```

```
columns = (0 1 1 1 2)
```

```
rowIndex = (0 2 3 5)
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix F :

$$F = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix F can be represented as a 3x3 block matrix G with the following structure:

$$G = \begin{bmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, M' = \begin{bmatrix} 6 & 8 \\ 7 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 2 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The symmetric matrix F can be represented in this 3-array variation of the BSR format (storing only upper triangular) as follows:

one-based indexing

`values = (1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0)`

`columns = (1 2 2 3)`

`rowIndex = (1 3 4 5)`

zero-based indexing

`values = (1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0)`

`columns = (0 1 1 2)`

`rowIndex = (0 2 3 4)`

Routine and Function Arguments

B

The major arguments in the BLAS routines are vector and matrix, whereas VML functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length n and increment $incx$ is passed in a one-dimensional array x whose values are defined as

$$x(1), x(1+|incx|), \dots, x(1+(n-1)*|incx|)$$

If $incx$ is positive, then the elements in array x are stored in increasing order. If $incx$ is negative, the elements in array x are stored in decreasing order with the first element defined as $x(1+(n-1)*|incx|)$. If $incx$ is zero, then all elements of the vector have the same value, $x(1)$. The dimension of the one-dimensional array that stores the vector must always be at least

$$idimx = 1 + (n-1)*|incx|$$

Example B-1 One-dimensional Real Array

Let $x(1:7)$ be the one-dimensional real array

$$x = (1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0).$$

If $incx = 2$ and $n = 3$, then the vector argument with elements in order from first to last is $(1.0, 5.0, 9.0)$.

If $incx = -2$ and $n = 4$, then the vector elements in order from first to last is $(13.0, 9.0, 5.0, 1.0)$.

If $incx = 0$ and $n = 4$, then the vector elements in order from first to last is $(1.0, 1.0, 1.0, 1.0)$.

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified. In Fortran, storing the m -by- n matrix is based on column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is m , and the increment between elements on the same diagonal is $m + 1$.

Example B-2 Two-dimensional Real Matrix

Let a be the real 5 x 4 matrix declared as `REAL A (5,4)`.

To scale the third column of a by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
callsscal (5, 2.0, a(1,3), 1)
```

To scale the second row, use the statement:

```
callsscal (4, 2.0, a(2,1), 5)
```

To scale the main diagonal of A by 2.0, use the statement:

```
callsscal (5, 2.0, a(1,1), 6)
```

NOTE. The default vector argument is assumed to be 1.

Vector Arguments in VML

Vector arguments of VML mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length n is passed contiguously in an array a whose values are defined as $a[0]$, $a[1]$, ..., $a[n-1]$ (for C- interface).

To accommodate for arrays with other increments, or more complicated indexing, VML contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array a as

```
a[m0], a[m1], ..., a[mn-1]
```

and need to be regrouped into an array y as

```
y[k0], y[k1], ..., y[kn-1],
```

VML pack/unpack functions can use one of the following indexing methods:

Positive Increment Indexing

```
kj = incy * j, mj = inca * j, j = 0, ..., n-1
```

Constraint: $incy > 0$ and $inca > 0$.

For example, setting $incy = 1$ specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

$kj = iy[j], mj = ia[j], j = 0, \dots, n-1,$

where ia and iy are arrays of length n that contain index vectors for the input and output arrays a and y , respectively.

Mask Vector Indexing

Indices kj, mj are such that:

$my[kj] \neq 0, ma[mj] \neq 0, j = 0, \dots, n-1,$

where ma and my are arrays that contain mask vectors for the input and output arrays a and y , respectively.

Matrix Arguments

Matrix arguments of the Intel® Math Kernel Library routines can be stored in either one- or two-dimensional arrays, using the following storage schemes:

- conventional full storage (in a two-dimensional array)
- packed storage for Hermitian, symmetric, or triangular matrices (in a one-dimensional array)
- band storage for band matrices (in a two-dimensional array).

Full storage is the following obvious scheme: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.

If a matrix is triangular (upper or lower, as specified by the argument *uplo*), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if $uplo = 'U'$, a_{ij} is stored in $a(i, j)$ for $i \leq j$, other elements of a need not be set.

if $uplo = 'L'$, a_{ij} is stored in $a(i, j)$ for $j \leq i$, other elements of a need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument *uplo*) is packed by columns in a one-dimensional array ap :

if $uplo = 'U'$, a_{ij} is stored in $ap(i+j(j-1)/2)$ for $i \leq j$

if $uplo = 'L'$, a_{ij} is stored in $ap(i + (2*n-j)*(j-1)/2)$ for $j \leq i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in p .

Band storage is as follows: an m -by- n band matrix with kl non-zero sub-diagonals and ku non-zero super-diagonals is stored compactly in a two-dimensional array ab with $kl+ku+1$ rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in rows of the array. Thus,

a_{ij} is stored in $ab(kl+1+i-j, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

Use the band storage scheme only when kl and ku are much less than the matrix size n . Although the routines work correctly for all values of kl and ku , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$m = n = 6$, $kl = 2$, $ku = 1$

Array elements marked * are not used by the routines:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0						
a_{21}	a_{22}	a_{23}	0	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
a_{31}	a_{42}	a_{43}	a_{34}	0	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{31}	a_{42}	a_{53}	a_{64}	*	*
0	0	0	a_{64}	a_{65}	a_{66}						

When a general band matrix is supplied for *LU factorization*, space must be allowed to store kl additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with $kl + ku$ super-diagonals. Thus,

a_{ij} is stored in $ab(kl+ku+1+i-j, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

The band storage scheme for LU factorization is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0	*	*	*	+	+	+
a_{21}	a_{22}	a_{23}	0	0	0	*	*	+	+	+	+
a_{31}	a_{42}	a_{43}	a_{34}	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	0	a_{64}	a_{65}	a_{66}	a_{31}	a_{42}	a_{53}	a_{64}	*	*

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

*	*	*	u_{14}	u_{25}	u_{36}
*	*	u_{13}	u_{24}	u_{35}	u_{46}
*	u_{12}	u_{23}	u_{34}	u_{45}	u_{56}
u_{11}	u_{22}	u_{33}	u_{44}	u_{55}	u_{66}
m_{21}	m_{32}	m_{43}	m_{54}	m_{65}	*
m_{31}	m_{42}	m_{53}	m_{64}	*	*

where u_{ij} are the elements of the upper triangular matrix U, and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either $kl = 0$ if upper triangular, or $ku = 0$ if lower triangular. For symmetric or Hermitian band matrices with k sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* = 'U', a_{ij} is stored in $ab(k+1+i-j, j)$ for $\max(1, j-k) \leq i \leq j$

if $uplo = 'L'$, a_{ij} is stored in $ab(1+i-j, j)$ for $j \leq i \leq \min(n, j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in b .

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n'	normal (no conjugation, no transposition)
'T' or 't'	transpose
'C' or 'c'	conjugate transpose.

Example B-3 Two-Dimensional Complex Array

Suppose $A(1:5, 1:4)$ is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let $transa$ be the transposition parameter, m be the number of rows, n be the number of columns, and lda be the leading dimension. Then if

$transa = 'N'$, $m = 4$, $n = 2$, and $lda = 5$, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'T'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (2.1, 0.21) & (3.1, 0.31) & (4.1, 0.41) \\ (1.2, 0.12) & (2.2, 0.22) & (3.2, 0.32) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'C'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array `A` above is declared as `COMPLEX A (5,4)`.

Then if `transa = 'N'`, `m = 3`, `n = 4`, and `lda = 4`, the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

Code Examples

This appendix presents code examples of using some Intel MKL routines and functions. You can find here example code written in both Fortran and C.

Currently, the appendix includes the following sections:

- [BLAS Code Examples](#)
- [PARDISO Code Examples](#)
- [Direct Sparse Solver Code Examples](#)
- [Iterative Sparse Solver Code Examples](#)
- [Preconditioner Code Examples](#)
- [Fourier Transform Functions Code Examples](#)
- [PDE Support Code Examples](#).

Please refer to respective chapters in the manual for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example C-1. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors x and y .

Parameters

<i>n</i>	Specifies the number of elements in vectors x and y .
<i>incx</i>	Specifies the increment for the elements of x .
<i>incy</i>	Specifies the increment for the elements of y .

```
program dot_main
real x(10), y(10), sdot, res
integer n, incx, incy, i
external sdot
n = 5
incx = 2
incy = 1
do i = 1, 10
    x(i) = 2.0e0
```

```

      y(i) = 1.0e0
    end do
    res = sdot (n, x, incx, y, incy)
    print*, `SDOT = `, res
  end

```

As a result of this program execution, the following line is printed:

SDOT = 10.000

Example C-2. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector x to a vector y .

Parameters

n	Specifies the number of elements in vectors x and y .
$incx$	Specifies the increment for the elements of x .
$incy$	Specifies the increment for the elements of y .

```

program copy_main
  real x(10), y(10)
  integer n, incx, incy, i
  n = 3
  incx = 3
  incy = 1
  do i = 1, 10
    x(i) = i
  end do
  call scopy (n, x, incx, y, incy)
  print*, `Y = `, (y(i), i = 1, n)
end

```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example C-3. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

$a := \alpha x y' + a.$

Parameters

α	Specifies a scalar α .
----------	-------------------------------

Parameters

x *m*-element vector.
y *n*-element vector.
a *m*-by-*n* matrix.

```

program ger_main
real a(5,3), x(10), y(10), alpha
integer m, n, incx, incy, i, j, lda
m = 2
n = 3
lda = 5
incx = 2
incy = 1
alpha = 0.5
do i = 1, 10
  x(i) = 1.0
  y(i) = 1.0
end do
do i = 1, m
  do j = 1, n
    a(i,j) = j
  end do
end do
call sger (m, n, alpha, x, incx, y, incy, a, lda)
print*, `Matrix A: `
do i = 1, m
  print*, (a(i,j), j = 1, n)
end do
end

```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

1.50000 2.50000 3.50000

1.50000 2.50000 3.50000

Example C-4. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

$c := \alpha a * b' + \beta c.$

Parameters

alpha Specifies a scalar *alpha*.

Parameters

<i>beta</i>	Specifies a scalar <i>beta</i> .
<i>a</i>	Symmetric matrix
<i>b</i>	<i>m</i> -by- <i>n</i> matrix
<i>c</i>	<i>m</i> -by- <i>n</i> matrix

```

program symm_main
real a(3,3), b(3,2), c(3,3), alpha, beta
integer m, n, lda, ldb, ldc, i, j
character uplo, side
uplo = 'u'
side = 'l'
m = 3
n = 2
lda = 3
ldb = 3
ldc = 3
alpha = 0.5
beta = 2.0
do i = 1, m
    do j = 1, m
        a(i,j) = 1.0
    end do
end do
do i = 1, m
    do j = 1, n
        c(i,j) = 1.0
        b(i,j) = 2.0
    end do
end do
call ssymm (side, uplo, m, n, alpha,
a, lda, b, ldb, beta, c, ldc)
print*, `Matrix C: `
do i = 1, m
    print*, (c(i,j), j = 1, n)
end do
end

```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

```

5.00000 5.00000
5.00000 5.00000
5.00000 5.00000

```

The following example illustrates a call from a C program to the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Example C-5. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure `c`.

```
#define N 5
void main()
{
    int n, inca = 1, incb = 1, i;
    typedef struct{ double re; double im; } complex16;
    complex16 a[N], b[N], c;
    void zdotc();
    n = N;
    for( i = 0; i < n; i++ ){
        a[i].re = (double)i; a[i].im = (double)i * 2.0;
        b[i].re = (double)(n - i); b[i].im = (double)i * 2.0;
    }
    zdotc( &c, &n, a, &inca, b, &incb );
    printf( "The complex dot product is: ( %6.2f, %6.2f )\n", c.re, c.im );
}
```

NOTE. Instead of calling BLAS directly from C programs, you might wish to use the CBLAS interface; this is the supported way of calling BLAS from C. For more information about CBLAS, see [Appendix D](#), which presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

PARDISO Code Examples

This section presents code examples of using the PARDISO direct solver for computing solutions of linear systems with sparse matrices. For description of this solver, refer to Chapter 8 of the manual.

Examples for Sparse Symmetric Linear Systems

In this section two examples (Fortran, C) are provided to solve symmetric linear systems with PARDISO. To solve the systems of equations $Ax = b$, where

$$A = \begin{bmatrix} 7.0 & 0.0 & 1.0 & 0.0 & 0.0 & 2.0 & 7.0 & 0.0 \\ 0.0 & -4.0 & 8.0 & 0.0 & 2.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 8.0 & 1.0 & 0.0 & 0.0 & 0.0 & 0.0 & 5.0 \\ 0.0 & 0.0 & 0.0 & 7.0 & 0.0 & 0.0 & 9.0 & 0.0 \\ 0.0 & 2.0 & 0.0 & 0.0 & 5.0 & 1.0 & 5.0 & 0.0 \\ 2.0 & 0.0 & 0.0 & 0.0 & 1.0 & -1.0 & .0 & 5.0 \\ 7.0 & 0.0 & 0.0 & 9.0 & 5.0 & 0.0 & 11.0 & 0.0 \\ 0.0 & 0.0 & 5.0 & 0.0 & 0.0 & 5.0 & 0.0 & 5.0 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \end{bmatrix}$$

Example Results for Symmetric Systems

Upon successful execution of the solver, the result of the solution x is as follows

```
Reordering completed ...
Number of nonzeros in factors = 30
Number of factorization MFLOPS = 0
Factorization completed ...
Solve completed ...
The solution of the system is
x(1) = -0.0418602013
x(2) = -0.00341312416
x(3) = 0.117250377
x(4) = -0.11263958
x(5) = 0.0241722445
x(6) = -0.10763334
x(7) = 0.198719673
x(8) = 0.190382964
```

Examples for Sparse Unsymmetric Linear Systems

In this section two examples (Fortran, C) are provided to solve unsymmetric linear systems with PARDISO. To solve the systems of equations $Ax = b$, where

$$A = \begin{bmatrix} 1.0 & -1.0 & 0.0 & -3.0 & 0.0 \\ -2.0 & 5.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 4.0 & 6.0 & 4.0 \\ -4.0 & 0.0 & 2.0 & 7.0 & 0.0 \\ 0.0 & 8.0 & 0.0 & 0.0 & -5.0 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \end{bmatrix}$$

Example Results for Unsymmetric Systems

Upon successful execution of the solver, the result of the solution x is as follows

```

Reordering completed ...
Number of nonzeros in factors = 21
Number of factorization MFLOPS = 0
Factorization completed ...
Solve completed ...
The solution of the system is
x( 1) = -0.522321429
x( 2) = -0.00892857143
x( 3) =  1.22098214
x( 4) = -0.504464286
x( 5) = -0.214285714

```

Direct Sparse Solver Code Examples

This section contains example code in FORTRAN 77, Fortran 90 and C. For description of the sparse solver routines used in this code, refer to "Direct Sparse Solver (DSS) Interface Routines" in Chapter 8 of the manual . The example code solves the equations presented in Direct Method section of Appendix A - a symmetric positive definite system of equations $Ax=b$ with a sparse matrix, where

$$A = \begin{bmatrix} 9 & 1.5 & 6 & 0.75 & 3 \\ 1.5 & 0.5 & 0 & 0 & 0 \\ 6 & 0 & 12 & 0 & 0 \\ 0.75 & 0 & 0 & 0.625 & 0 \\ 3 & 0 & 0 & 0 & 16 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

Example results for symmetric systems

Upon successful execution of the solver, the determinant and the result of the solution array are as follows

```

pow of determinant is      0.000
base of determinant is     2.250
Determinant is             2.250
Solution Array:  -326.333   983.000  163.417   398.000   61.500

```

Iterative Sparse Solver Code Examples

This section contains example code in FORTRAN 77 and C. For description of the iterative sparse solver routines based on the reverse communication interface (RCI ISS) used in this code, refer to "Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)" in Chapter 8 of the manual . More examples can be found in the `examples/solver` subdirectory of the Intel MKL installation directory.

Example of Use RCI (Preconditioned) Conjugate Gradient Solver for Systems with Single Right Hand Side

Example results for symmetric positive definite systems. Upon successful execution of the solver, the result of the solution array is as follows:

```
The system has been solved
The following solution obtained
  1.000    0.000    1.000    0.000
  1.000    0.000    1.000    0.000
Expected solution
  1.000    0.000    1.000    0.000
  1.000    0.000    1.000    0.000
Number of iterations: 8
This example has successfully PASSED through all steps of computation!
```

Examples of Use RCI (Preconditioned) Conjugate Gradient Solver for Systems with Multiple Right Hand Sizes (MRHS)

Example results for symmetric positive definite systems. Upon successful execution of the solver, the result of the solution array is as follows:

```

The system has been solved
The following solution obtained
  1.000    0.000    1.000    0.000
  1.000    0.000    1.000    0.000
  0.000    2.000    0.000    2.000
  0.000    2.000    0.000    2.000
Expected solution
  1.000    0.000    1.000    0.000
  1.000    0.000    1.000    0.000
  0.000    2.000    0.000    2.000
  0.000    2.000    0.000    2.000
This example has successfully PASSED through all steps of computation!

```

Fortran Example of Using RCI (Preconditioned) Flexible Generalized Minimal Residual Solver.

Fortran example results for a non-symmetric indefinite system. Upon successful execution of the solver, the following result is printed (up to rounding errors that depend on the computer system used):

```
-----
The SIMPLEST example of usage of RCI FGMRES solver
to solve a non-symmetric indefinite non-degenerate
algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As IPAR(8)=1, the automatic test for the maximal number of iterations will be
performed
+++
As IPAR(9)=1, the automatic residual test will be performed
+++
As IPAR(10)=0, the user-defined stopping test will not be requested, thus,
RCI_REQUEST will not take the value 2
+++
As IPAR(11)=0, the Preconditioned FGMRES iterations will not be performed,
thus, RCI_REQUEST will not take the value 3
+++
As IPAR(12)=1, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be performed,
thus, RCI_REQUEST will not take the value 4
+++

The system has been solved

The following solution has been obtained:
COMPUTED_SOLUTION(1)=-0.100E+01
COMPUTED_SOLUTION(2)= 0.100E+01
COMPUTED_SOLUTION(3)=-0.805E-15
COMPUTED_SOLUTION(4)= 0.100E+01
COMPUTED_SOLUTION(5)=-0.100E+01

The expected solution is:
EXPECTED_SOLUTION(1)=-0.100E+01
```

```

EXPECTED_SOLUTION(2)= 0.100E+01
EXPECTED_SOLUTION(3)= 0.000E+00
EXPECTED_SOLUTION(4)= 0.100E+01
EXPECTED_SOLUTION(5)=-0.100E+01

```

Number of iterations: 5
This example has successfully PASSED through all steps of computation!

Example C-15a. Fortran Example to Solve Non-Symmetric Indefinite System

C Example of Using RCI (Preconditioned) Flexible Generalized Minimal Residual Solver.

C example results for the same non-symmetric indefinite system as in the previous example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example the addresses for input/result are adjusted for user-defined operations from `IPAR(22)` to `ipar[21]-1`, and from `IPAR(23)` to `ipar[22]-1`, respectively. Upon successful execution of the solver, the following result is printed (up to rounding errors that depend on the computer system used):

```
-----
-----
The SIMPLEST example of usage of RCI FGMRES solver
to solve a non-symmetric indefinite non-degenerate
algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As ipar[7]=1, the automatic test for the maximal number of iterations will be
performed
+++
As ipar[8]=1, the automatic residual test will be performed
+++
As ipar[9]=0, the user-defined stopping test will not be requested, thus,
RCI_request will not take the value 2
+++
As ipar[10]=0, the Preconditioned FGMRES iterations will not be performed,
thus, RCI_request will not take the value 3
+++
As ipar[11]=1, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be performed,
thus, RCI_request will not take the value 4
+++

The system has been solved

The following solution has been obtained:
computed_solution[0]=-1.000000e+00
computed_solution[1]=1.000000e-00
computed_solution[2]=-8.049117e-16
computed_solution[3]=1.000000e-00
computed_solution[4]=-1.000000e+00

The expected solution is:
expected_solution[0]=-1.000000e+00
expected_solution[1]=1.000000e+00
expected_solution[2]=0.000000e+00
expected_solution[3]=1.000000e+00
```

```
expected_solution[4]=-1.000000e+00
```

```
Number of iterations: 5
```

This example has successfully PASSED through all steps of computation!

Example C-15b. C Example to Solve Non-Symmetric Indefinite System

```

Fourier Transform Functions Code Examples

This section presents code examples of functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” sections in the “Fourier Transform Functions” chapter. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- [Auxiliary data transformations](#).

FFT Code Examples

This section presents code examples of using the FFT interface functions described in “[Fourier Transform Functions](#)” chapter. Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

Example C-16 One-dimensional In-place FFT (Fortran Interface)

```

! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X(32)
Real :: Y(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
!...put input data into X(1),...,X(32); Y(1),...,Y(32)

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
    DFTI_COMPLEX, 1, 32 )
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X )
Status = DftiFreeDescriptor(My_Desc1_Handle)

```

```

! result is given by {X(1),X(2),...,X(32)}

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,&
    DFTI_REAL, 1, 32)
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given in CCS format.

```

Example C-16a One-dimensional Out-of-place FFT (Fortran Interface)

```

! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_in(32)
Complex :: X_out(32)
Real :: Y_in(32)
Real :: Y_out(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
...put input data into X_in(1),...,X_in(32); Y_in(1),...,Y_in(32)
! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,
DFTI_COMPLEX, 1, 32 )
Status = DftiSetValue( My_Desc1_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X_in, X_out )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X_out(1),X_out(2),...,X_out(32)}
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,
DFTI_REAL, 1, 32)
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y_in, Y_out)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by Y_out in CCS format.

```

Example C-17 One-dimensional In-place FFT (C Interface)

```

/* C example, float_Complex is defined in C9X */
#include "mkl_dfti.h"
float_Complex x[32];
float y[34];

```

```
DFTI_DESCRIPTOR *my_desc1_handle,*my_desc2_handle;
/* .... or alternatively
dfti_descriptor_handle my_desc1_handle, my_desc2_handle; */
MKL_LONG status;
//...put input data into x[0],...,x[31]; y[0],...,y[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x[0], ..., x[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 1, 32);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given in CCS format*/
```

Example C-17a One-dimensional Out-of-place FFT (C Interface)

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x_in[32];
float _Complex x_out[32];
float y_in[32];
float y_out[34];

DFTI_DESCRIPTOR *my_desc1_handle,*my_desc2_handle;
/* .... or alternatively
dfti_descriptor_handle my_desc1_handle, my_desc2_handle; */
MKL_LONG status;
//...put input data into x_in[0],...,x_in[31]; y_in[0],...,y_in[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x_out[0], ..., x_out[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 1, 32);
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y_in, y_out);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*/
```

Example C-18 Two-dimensional FFT (Fortran Interface)

The following is an example of two simple two-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran example.
! 2D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X 2D(32,100)
Real :: Y 2D(32, 102)
Complex :: X(3200)
Real :: Y(3468)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status, L(2)
!...put input data into X_2D(j,k), Y_2D(j,k), 1<=j<=32, 1<=k<=100
!...set L(1) = 32, L(2) = 100
!...the transform is a 32-by-100

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
    DFTI_COMPLEX, 2, L)
Status = DftiCommitDescriptor( My_Desc1_Handle)
Status = DftiComputeForward( My_Desc1_Handle, X)
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by X_2D(j,k), 1<=j<=32, 1<=k<=100

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE,&
    DFTI_REAL, 2, L)
Status = DftiCommitDescriptor( My_Desc2_Handle)
Status = DftiComputeForward( My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by the complex value z(j,k) 1<=j<=32; 1<=k<=100
! and is stored in CCS format
```

Example C-19 Two-dimensional FFT (C Interface)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x[32][100];
float y[34][102];
DFTI_DESCRIPTOR *my_desc1_handle, my_desc2_handle;
```

```

MKL_LONG status, l[2];
//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 2, 1);
status = DftiCommitDescriptor( my_desc1_handle);
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 2, 1);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/

```

The following examples demonstrate how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of the `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

Example C-20 Changing Default Settings (Fortran)

The code below illustrates how this can be done:

```

! Fortran example
! 1D complex to complex, not in place
Use MKL_DFTI
Complex :: X_in(32), X_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status
!...put input data into X_in(j), 1<=j<=32
Status = DftiCreateDescriptor( My_Desc_Handle,& DFTI_SINGLE, DFTI_COMPLEX, 1, 32)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X_in, X_out)
Status = DftiFreeDescriptor( My_Desc_Handle)
! result is X_out(1),X_out(2),...,X_out(32)

```

Example C-21 Changing Default Settings (C)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
/* or alternatively
DFTI_DESCRIPTOR *my_desc_handle;*/
MKL_LONG status;
//...put input data into x_in[j], 0 <= j < 32
status = DftiCreateDescriptor(&my_desc_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiSetValue(my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is x_out[0], x_out[1], ..., x_out[31] */
```

Example C-22 Using Status Checking Functions

The example illustrates the use of status checking functions described in [Chapter 11](#).

```
/* C */
DFTI_DESCRIPTOR_HANDLE desc;
MKL_LONG status;
// . . . descriptor creation and other code
status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status, DFTI_NO_ERROR))
{
    printf ('Error: %s\n', DftiErrorMessage(status));
}

! Fortran
type(DFTI_DESCRIPTOR), POINTER :: desc
integer status
! ...descriptor creation and other code
status = DftiCommitDescriptor(desc)
if (status .ne. 0) then
    if (.not. DftiErrorClass(status, DFTI_NO_ERROR)) then
        print *, 'Error: ', DftiErrorMessage(status)
    endif
endif
endif
```

Example C-23. Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran
use mkl_dfti
Complex :: X_2D(20,40)
Complex :: X(800)
Equivalence (X_2D, X)
INTEGER :: STRIDE(2)
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim1
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim2
! ...
Status = DftiCreateDescriptor(Desc_Handle_Dim1, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 20)
Status = DftiCreateDescriptor(Desc_Handle_Dim2, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 40)
! perform 40 one-dimensional transforms along 1st dimension
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_INPUT_DISTANCE, 20 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_OUTPUT_DISTANCE, 20 )
Status = DftiCommitDescriptor( Desc_Handle_Dim1 )
Status = DftiComputeForward( Desc_Handle_Dim1, X )
! perform 20 one-dimensional transforms along 2nd dimension
Stride(1) = 0; Stride(2) = 20
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_STRIDES, Stride )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_STRIDES, Stride )
Status = DftiCommitDescriptor( Desc_Handle_Dim2 )
Status = DftiComputeForward( Desc_Handle_Dim2, X )
Status = DftiFreeDescriptor( Desc_Handle_Dim1 )
Status = DftiFreeDescriptor( Desc_Handle_Dim2 )

/* C */
#include "mkl_dfti.h"
float_Complex x[20][40];
MKL_LONG stride[2];
MKL_LONG status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim2;
//...
status = DftiCreateDescriptor( &desc_handle_dim1, DFTI_SINGLE,
                             DFTI_COMPLEX, 1, 20 );
status = DftiCreateDescriptor( &desc_handle_dim2, DFTI_SINGLE,
```

```

DFTI_COMPLEX, 1, 40 );

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
stride[0] = 0; stride[1] = 40;
status = DftiSetValue( desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_STRIDES, stride );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride );
status = DftiCommitDescriptor( desc_handle_dim1 );
status = DftiComputeForward( desc_handle_dim1, x );
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue( desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 );
status = DftiSetValue( desc_handle_dim2,
DFTI_INPUT_DISTANCE, 40 );
status = DftiSetValue( desc_handle_dim2,
DFTI_OUTPUT_DISTANCE, 40 );
status = DftiCommitDescriptor( desc_handle_dim2 );
status = DftiComputeForward( desc_handle_dim2, x );
status = DftiFreeDescriptor( &Desc_Handle_dim1 );
status = DftiFreeDescriptor( &Desc_Handle_dim2 );

```

The following are examples of real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example C-24](#) is two-dimensional in-place transform and [Example C-24a](#) is two-dimensional out-of-place transform in Fortran interface. [Example C-25](#) is three-dimensional out-of-place transform in C interface. Note that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

Example C-24. Two-Dimensional REAL In-place FFT (Fortran Interface)

```

! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X 2D(34,100) ! 34 = (32/2 + 1)*2
Real :: X(3400)
Equivalence (X 2D, X)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_in(3)
Integer :: strides_out(3)
! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100

```

```
! ...set strides_in(1) = 0, strides_in(2) = 1, strides_in(3) = 34
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17
! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE,&
DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue(My_Desc_Handle, DFTI_INPUT_STRIDES, strides_in)
Status = DftiSetValue(My_Desc_Handle, DFTI_OUTPUT_STRIDES, strides_out)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X )
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in real matrix X_2D in CCE format.
```

Example C-24a. Two-Dimensional REAL Out-of-place FFT (Fortran Interface)

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(32,100)
Complex :: Y_2D(17, 100) ! 17 = 32/2 + 1
Real :: X(3200)
Complex :: Y(1700)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_out(3)

! ...put input data into X_2D(j,k), 1<=j<=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17

! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_OUTPUT_STRIDES, strides_out)

Status = DftiCommitDescriptor(My_Desc_Handle)
Status = DftiComputeForward(My_Desc_Handle, X, Y)
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in complex matrix Y_2D in CCE format.
```

Example C-25 Three-Dimensional REAL FFT (C Interface)

```

/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float_Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
/* or alternatively
DFTI_DESCRIPTOR *my_desc_handle*/
MKL_LONG status, l[3];
MKL_LONG strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, l );
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE );
status = DftiSetValue(my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x, y);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value z(j,k,s) 0<=j<=31; 0<=k<=99, 0<=s<=9
and is stored in complex matrix y in CCE format. */

```

Examples of Using Multi-Threading for FFT Computation

The following sample program shows how to employ internal threading in Intel MKL for FFT computation (see case "a" in ["Number of user threads"](#)).

To specify the number of threads inside Intel MKL, use the following settings:

set MKL_NUM_THREADS = 1 for one-threaded mode;

set MKL_NUM_THREADS = 4 for multi-threaded mode.

Note that the configuration parameter DFTI_NUMBER_OF_USER_THREADS must be equal to its default value 1.

Example C-26 Using Intel MKL Internal Threading Mode

```
#include "mkl_dfti.h"

void main () {

float x[200][100];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
MKL_LONG status, len[2];
//...put input data into x[j][k] 0<=j<=199, 0<=k<=99

len[0] = 200; len[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,DFTI_REAL, 2,
    len);
status = DftiCommitDescriptor(
my_desc1_handle);
status = DftiComputeForward(
my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
}
```

The following [Example C-27](#) and [Example C-27a](#) illustrate a parallel customer program with each descriptor instance used only in a single thread (see cases "b" and "c" in [Number of user threads](#)).

Specify the number of threads for [Example C-27](#) like this:

set `MKL_SERIAL = yes` (or `YES`) for Intel MKL to work in the single-threaded mode (recommended);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have its default value of 1.

Example C-27 Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL (case "a"). To achieve this, you need to set the parameter `DFTI_NUMBER_OF_TRANSFORMS = 4` and to set the corresponding parameter `DFTI_INPUT_DISTANCE = 5000`.

```
#include "mkl_dfti.h"
#include "omp.h"
void main ()
{
    float _Complex x[200][100];
```

```

MKL_LONG len[2];
//...put input data into x[j][k] 0<=j<=199, 0<=k<=99
len[0] = 50; len[1] = 100;

// each thread calculates real FFT for matrix (50*100)
#pragma omp parallel
{
    DFTI_DESCRIPTOR_HANDLE my_desc_handle;
    MKL_LONG myStatus;
    int myID = omp_get_thread_num ();

myStatus    =  DftiCreateDescriptor (&my_desc_handle, DFTI_SINGLE,
DFTI_COMPLEX, 2, len);
    myStatus = DftiCommitDescriptor (my_desc_handle);
    myStatus = DftiComputeForward (my_desc_handle, &x[myID * len[0] * len[1]]);
    myStatus = DftiFreeDescriptor (&my_desc_handle);
} /* End OpenMP parallel region */
}

```

Specify the number of threads for [Example C-27a](#) like this:

set `MKL_NUM_THREADS = 1` for Intel MKL to work in the single-threaded mode (obligatory);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have the default value of 1.

Example C-27a Using Parallel Mode with Multiple Descriptors Initialized in One Thread

```

#include "mkl_dfti.h"
#include "omp.h"
void main ()
{
    float _Complex x[200][100];
    MKL_LONG len[2];
    MKL_LONG i;
    //...put input data into x[j][k] 0<=j<=199, 0<=k<=99
    len[0] = 50; len[1] = 100;
    DFTI_DESCRIPTOR_HANDLE my_desc_handle[4];
    MKL_LONG myStatus;
    for (i=0; i<3; i++) myStatus = DftiCreateDescriptor (&my_desc_handle[i], DFTI_SINGLE, DFTI_COMPLEX,
    2, len);
    // each thread calculates real FFT for matrix (50*100)
    #pragma omp parallel
    {
        int myID = omp_get_thread_num ();
        myStatus = DftiCommitDescriptor (my_desc_handle[myID]);
        myStatus = DftiComputeForward (my_desc_handle[myID], &x[myID * len[0] * len[1]]);
    }
}

```

```

} /* End OpenMP parallel region */
for (i=0;i<3;i++) myStatus = DftiFreeDescriptor (&my_desc_handle[i]);
}

```

The following [Example C-28](#) illustrates a parallel customer program with a common descriptor used in several threads (see case "d" in ["Number of user threads"](#)).

In this case, the number of threads, as well as any other configuration parameter, must not be changed after FFT initialization by the `DftiCommitDescriptor()` function is done.

Example C-28 Using Parallel Mode with a Common Descriptor

```

// set number of threads inside Intel MKL:
//rem set MKL_SERIAL = YES - is not required
// since one-threaded mode for Intel MKL is forced automatically
// set OMP_NUM_THREADS = 4 - multi-threaded mode for customer

#include "mkl_dfti.h"
#include "omp.h"
void main ()
{
    float_Complex x[200][100];
    MKL_LONG status;
    DFTI_DESCRIPTOR_HANDLE desc_handle;
    int nThread = omp_get_max_threads ();
    MKL_LONG len[2];
    //...put input data into x[j][k] 0<=j<=199, 0<=k<=99
    len[0] = 50; len[1] = 100;

    status =
DftiCreateDescriptor (&desc_handle, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    status = DftiSetValue (desc_handle,
DFTI_NUMBER_OF_USER_THREADS, nThread);
    status = DftiCommitDescriptor (desc_handle);

    // each thread calculates real FFT for matrix (50*100)
    #pragma omp parallel num_threads(nThread)
    {
        MKL_LONG myStatus;
        int myID = omp_get_thread_num ();

        myStatus = DftiComputeForward (desc_handle, &x[myID * len[0] * len[1]]);
    } /* End OpenMP parallel region */

    status = DftiFreeDescriptor (&desc_handle);
}

```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

Example 29. 2D Out-of-place Cluster FFT Computation

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len[2],v,i,j,n,s;
Complex *in,*out;

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,2,len);
// Ask necessary length of in and out arrays and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
    for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();
```

Example 30. 1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len, v, i, n_out, s_out;
Complex *in, *work;

MPI_Init(...);
// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD, &desc, DFTI_DOUBLE, DFTI_COMPLEX, 1, 1, len);
// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc, CDFT_LOCAL_SIZE, &v);
in = (Complex*)malloc(v * sizeof(Complex));
work = (Complex*)malloc(v * sizeof(Complex));
// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc, CDFT_LOCAL_NX, &n);
DftiGetValueDM(desc, CDFT_LOCAL_X_START, &s);
// Set work array as a workspace
DftiSetValueDM(desc, CDFT_WORKSPACE, work);
// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0; i<n; i++) in[i]=f(i+s);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc, in);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_NX, &n_out);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_X_START, &s_out);
// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]=g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();
```

Auxiliary Data Transformations

This section presents code examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Example C-30a Conversion from Cartesian to polar representation of complex data

```
// Cartesian->polar conversion of complex data
// Cartesian representation:  $z = re + I*im$ 
// Polar representation:  $z = r * \exp(I*phi)$ 
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
                        double *r,double *phi)
{
    vdHypot(n,re,im,r);          // compute radii r[]
    vdAtan2(n,re,im,phi);        // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                        double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);                // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_re,temp_im,phi); // compute phases phi[]
}
```

Example C-30b Conversion from polar to Cartesian representation of complex data

```
// Polar->Cartesian conversion of complex data.
// Polar representation:  $z = r * \exp(I*phi)$ 
// Cartesian representation:  $z = re + I*im$ 
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n,const double *r,const double *phi,
                        double *re,double *im)
{
    vdSinCos(n,phi,im,re);        // compute direction, i.e.  $z[]/abs(z[])$ 
    vdMul(n,r,re,re);            // scale real part
    vdMul(n,r,im,im);            // scale imaginary part
}

void
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
                        MKL_Complex16 *z,
                        double *temp_re,double *temp_im)
{
    vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e.  $z[]/abs(z[])$ 
}
```

```
vdMul(n,r,temp_im,temp_im); // scale imaginary part
vdMul(n,r,temp_re,temp_re); // scale real part
vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}
```

PDE Support Code Examples

This section presents code examples for routines described in the in the [“Partial Differential Equations Support” chapter](#). The examples are grouped in subsections

- [Trigonometric Transform Code Examples](#)
- [Poisson Library Code Examples](#).

Trigonometric Transforms Interface Code Examples

Code presented in this section computes solutions of three simple 1D Helmholtz problems with different boundary conditions: DD, NN and ND cases, where “D” denotes a Dirichlet boundary condition and “N” stands for a Neumann boundary condition. [Example C-31](#) implements the computations in C and [Example C-32](#) provides Fortran 90 code. You can find more examples in `examples/pdettc` and `examples/pdettf` subdirectories in the Intel MKL directory.

The algorithm of computing the solution uses [Trigonometric Transform routines](#), described in chapter 13. In the DD case, the sine transform is computed, the NN case uses the cosine transform and the ND case corresponds to the staggered cosine transform.

Other details of the Helmholtz problems being solved are printed out along with the computed solutions.

Upon successful execution of [Example C-31](#) the following text is printed out ([Example C-32](#) generates similar output):

```
Example of use of MKL Trigonometric Transforms
*****

This example gives the the solutions of the 1D differential problems
with the equation -u''+u=f(x), 0<x<1,
and with 3 types of boundary conditions:
DD case: u(0)=u(1)=0,
NN case: u'(0)=u'(1)=0,
ND case: u'(0)=u(1)=0.
-----
In general, the error should be of order O(1.0/n**2)
For this example, the value of n is 8
The approximation error should be of order 5.0e-002 if everything is OK
-----
```

```
=====
DOUBLE PRECISION COMPUTATIONS
=====
The computed solution of DD problem is

u[0]= 0.000
u[1]= 0.153
u[2]= 0.524
u[3]= 0.895
u[4]= 1.049
u[5]= 0.895
u[6]= 0.524
u[7]= 0.153
u[8]= 0.000

Error=4.873e-02

The computed solution of NN problem is

u[0]=-0.026
u[1]= 0.128
u[2]= 0.500
u[3]= 0.872
u[4]= 1.026
u[5]= 0.872
u[6]= 0.500
u[7]= 0.128
u[8]=-0.026

Error=2.583e-02

The computed solution of ND problem is

u[0]=-0.009
u[1]= 0.145
u[2]= 0.517
u[3]= 0.890
u[4]= 1.045
u[5]= 0.892
u[6]= 0.522
u[7]= 0.152
u[8]= 0.000

Error=4.470e-02

This example has successfully PASSED through all steps of computation!

Example C-31 shows C code of the computations.
```

Example C-31. C Example to Solve a Set of 1D Helmholtz Problems

Poisson Library Code Examples

Cartesian case

The code below computes an approximate solution of a 2D Poisson problem

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = 8\pi^2 \sin 2\pi x \cdot \sin 2\pi y$$

in the rectangle $0 < x < 1, 0 < y < 1$.

The following boundary conditions are imposed for the problem:

- Dirichlet boundary condition

$$u(0, y) = u(1, y) = 1$$

for $0 \leq y \leq 1$.

- Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, 0) = -2\pi \sin 2\pi x, \frac{\partial u}{\partial n}(x, 1) = 2\pi \sin 2\pi x$$

for $0 < x < 1$.

The exact solution is known to be

$$u(x, y) = \sin 2\pi x \cdot \sin 2\pi y + 1$$

Example [C-33](#) implements the computations in C and Example [C-34](#) provides Fortran 90 code. Mind that PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of Intel MKL FFT interface. You can find more examples in `examples/pdepoissonc` and `examples/pdepoissonf` subdirectories in the Intel MKL directory.

The algorithm of computing the approximate solution of a Poisson Problem uses [Poisson Library routines](#), described in chapter 13. Details of the Poisson problem being solved and the errors are printed out between the computed solution and the exact one.

Upon successful execution of Example [C-33](#) the following text is printed out (Example [C-34](#) produces similar output):

```
Example of use of MKL Poisson Library
*****
This example gives the solution of 2D Helmholtz problem
```

```

with the equation -u_xx-u_yy+u=f(x,y), 0<x<1, 0<y<1,
f(x,y)=(8*pi*pi+1)*sin(2*pi*x)*sin(2*pi*y)+1,
and with the following boundary conditions:
  u(0,y)=u(1,y)=1 (Dirichlet boundary conditions),
-u_y(x,0)=-2.0*pi*sin(2*pi*x) (Neumann boundary condition),
  u_y(x,1)= 2.0*pi*sin(2*pi*x) (Neumann boundary condition).

```

```

-----
In general, the error should be of order O(1.0/nx^2+1.0/ny^2)
For this example, the value of nx=ny is 6
The approximation error should be of order 1.0e-01, if everything is OK
-----

```

DOUBLE PRECISION COMPUTATIONS

```

=====
The number of mesh intervals in x-direction is nx=6
The number of mesh intervals in y-direction is ny=6

```

```

In the mesh point (0.167,0.000) the error between the computed and the true solution is
equal to -7.473e-02
In the mesh point (0.167,0.167) the error between the computed and the true solution is
equal to  4.377e-02
In the mesh point (0.167,0.333) the error between the computed and the true solution is
equal to  6.233e-02
In the mesh point (0.167,0.500) the error between the computed and the true solution is
equal to  2.220e-16
In the mesh point (0.167,0.667) the error between the computed and the true solution is
equal to -6.233e-02
In the mesh point (0.167,0.833) the error between the computed and the true solution is
equal to -4.377e-02
In the mesh point (0.167,1.000) the error between the computed and the true solution is
equal to  7.473e-02

```

```

Double precision 2D Helmholtz example has successfully PASSED
through all steps of computation!

```

Example C-33 shows C code of the computations.

```

Spherical case

The code below computes an approximate solution of a Helmholtz problem on the entire sphere:

$$-\Delta_s u = 3 \cos \theta, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

with $a_\phi = 0$, $b_\phi = 2\pi$, $a_\theta = 0$, $b_\theta = \pi$, and a boundary condition

$$\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\substack{\theta \rightarrow 0 \\ \theta \rightarrow \pi}} = 0$$

at the poles (*periodic* case).

The exact solution is known to be $u(\phi, \theta) = \cos \theta$.

Example [C-35](#) implements the computations in C and Example [C-36](#) provides Fortran 90 code. Mind that PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of Intel MKL FFT interface. You can find more examples in `examples/pdepoissonc` and `examples/pdepoissonf` subdirectories in the Intel MKL directory.

The algorithm of computing the approximate solution of a Poisson Problem uses [Poisson Library routines](#), described in chapter 13. Details of the Poisson problem being solved and the errors are printed out between the computed solution and the exact one. Upon successful execution of Example C-35 the following text is printed out (Example C-36 produces similar output):

Example of use of MKL Poisson Library

This example gives the solution of Helmholtz problem on a whole sphere
 $0 < p < 2\pi$, $0 < t < \pi$, with Helmholtz coefficient $q=1$ and right-hand side
 $f(p,t)=3*\cos(t)$

 In general, the error should be of order $O(1.0/np^2+1.0/nt^2)$
 For this example, the value of $np=nt$ is 8
 The approximation error should be of order $1.5e-01$, if everything is OK

Note that np should be even to solve the PERIODIC problem!

 DOUBLE PRECISION COMPUTATIONS
 =====

The number of mesh intervals in phi-direction is $np=8$
 The number of mesh intervals in theta-direction is $nt=8$

In the mesh point (0.785,0.000) the error between the computed and the true solution is equal to $-1.402e-01$
 In the mesh point (0.785,0.393) the error between the computed and the true solution is equal to $-3.097e-02$
 In the mesh point (0.785,0.785) the error between the computed and the true solution is equal to $-6.036e-03$
 In the mesh point (0.785,1.178) the error between the computed and the true solution is equal to $2.964e-04$
 In the mesh point (0.785,1.571) the error between the computed and the true solution is equal to $4.979e-17$
 In the mesh point (0.785,1.963) the error between the computed and the true solution is equal to $-2.964e-04$
 In the mesh point (0.785,2.356) the error between the computed and the true solution is equal to $6.036e-03$
 In the mesh point (0.785,2.749) the error between the computed and the true solution is equal to $3.097e-02$
 In the mesh point (0.785,3.142) the error between the computed and the true solution is equal to $1.402e-01$

Double precision Helmholtz example on a whole sphere has successfully PASSED through all steps of computation!

Note that actual figures in the error may slightly differ from the figures printed above depending on the architecture and operating system used to run the example.

Example C-35 shows C code for the problem.

Example C-35. C Example to Solve Helmholtz Problem on a Sphere

-----
The FULLY ADVANCED example RCI FGMRES with ILU0 preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

```

Some info about the current run of RCI FGMRES method:

```

As IPAR(8)=0, the automatic test for the maximal number of iterations will be skipped
+++
As IPAR(9)=0, the automatic residual test will be skipped
+++

```

```

As IPAR(10)=1, the user-defined stopping test will be requested via RCI_REQUEST=2
+++
As IPAR(11)=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_REQUEST=3
+++
As IPAR(12)=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_REQUEST=4
+++

```

The system has been solved

The following solution has been obtained:

```

COMPUTED_SOLUTION(1)= 0.100E+01
COMPUTED_SOLUTION(2)= 0.100E+01
COMPUTED_SOLUTION(3)= 0.100E+01
COMPUTED_SOLUTION(4)= 0.100E+01

```

The expected solution is:

```

EXPECTED_SOLUTION(1)= 0.100E+01
EXPECTED_SOLUTION(2)= 0.100E+01
EXPECTED_SOLUTION(3)= 0.100E+01
EXPECTED_SOLUTION(4)= 0.100E+01

```

Number of iterations: 2

```

-----
Fortran example of FGMRES with ILU0 preconditioner
has successfully PASSED all stages of computations
-----

```

NOTE. If the ILU0 preconditioner is not used, then the same code requires 7 iterations.

Example C-37. FORTRAN 77 Example to Solve Non-symmetric Non-degenerate Linear System

C-----
        CALL DFGMRES_INIT(N, COMPUTED_SOLUTION, RHS, RCI_REQUEST, IPAR,
1 DPAR, TMP)
        IF (RCI_REQUEST.NE.0) GOTO 999

C-----
C Calculate ILU0 preconditioner.
C !ATTENTION!
C DCSRILU0 routine uses some IPAR, DPAR set by DFGMRES_INIT routine.
C Important for DCSRILU0 default entries set by DFGMRES_INIT are
C ipar(2) = 6 - output of error messages to the screen,

```

```

C ipar(6) = 1 - allow output of error messages,
C ipar(31)= 0 - abort DCSRILU0 calculations if routine meets zero diagonal element.
C
C If ILU0 is going to be used out of MKL FGMRES context, than the values
C of ipar(2), ipar(6), ipar(31), dpar(31), and dpar(32) should be user
C provided before the DCSRILU0 routine call.
C
C In this example, specific for DCSRILU0 entries are set in turn:
C ipar(31)= 1 - change small diagonal value to that given by dpar(32),
C dpar(31)= 1.D-20 instead of the default value set by DFGMRES_INIT.
C           It is a small value to compare a diagonal entry with it.
C dpar(32)= 1.D-16 instead of the default value set by DFGMRES_INIT.
C           It is the target value of the diagonal value if it is
C           small as compared to dpar(31) and the routine should change
C           it rather than abort DCSRILU0 calculations.
C-----

      IPAR(31)=1
      DPAR(31)=1.D-20
      DPAR(32)=1.D-16
      CALL DCSRILU0(N, A, IA, JA, BILU0, IPAR, DPAR, IERR)
      NRM2=DNRM2(MATSIZE, BILU0, INCX)

      IF(IERR.ne.0) THEN
        WRITE(*,'(A,A,I1)') ' Error after calculation of the',
1' preconditioner DCSRILU0',IERR
        GOTO 998
      ENDIF

C-----
C Set the desired parameters:
C do the restart after 2 iterations
C LOGICAL parameters:
C do not do the stopping test for the maximal number of iterations
C do the Preconditioned iterations of FGMRES method
C Set parameter IPAR(11) for preconditioner call. For this example,
C it reduces the number of iterations.

C set the relative tolerance to 1.0D-3 instead of default value 1.0D-6

C Example of Using ILU0 Preconditioner with RCI FGMRES Solver

C example has the same non-degenerate system as in the previous FORTRAN 77 example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example we adjust the addresses for input/result for user-defined operations from `IPAR(22)` to `ipar[21]-1` and from `IPAR(23)` to `ipar[22]-1`, respectively. Specific to ILU0 preconditioner parameter entries are referred to as `ipar[30]`, `dpar[30]`, `dpar[31]`. Upon successful execution of the solver, the following information is printed (up to rounding errors that depend on the computer system):

```
-----
The FULLY ADVANCED example RCI FGMRES with ILU0 preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As ipar[7]=0, the automatic test for the maximal number of iterations will be
skipped
+++
As ipar[8]=0, the automatic residual test will be skipped
+++
As ipar[9]=1 the user-defined stopping test will be requested via
RCI_request=2
+++
As ipar[10]=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_request=3
+++
As ipar[11]=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_request=4
+++

The system has been solved

The following solution has been obtained:
computed_solution[0]=1.000000e+00
computed_solution[1]=1.000000e+00
computed_solution[2]=1.000000e+00
```

```
computed_solution[3]=1.000000e+00
```

```
The expected solution is:
```

```
expected_solution[0]=1.000000e+00
```

```
expected_solution[1]=1.000000e+00
```

```
expected_solution[2]=1.000000e+00
```

```
expected_solution[3]=1.000000e+00
```

```
Number of iterations: 2
```

```
-----
C example of FGMRES with ILU0 preconditioner
has successfully PASSED all stages of computations
-----
```

NOTE. If the ILU0 preconditioner is not used, then the same code requires 7 iterations.

Example C-38. C Example to Solve Non-symmetric Non-degenerate Linear System

Fortran Example of Using ILUT Preconditioner with RCI FGMRES Solver

Example results for non-degenerate system. Upon successful execution of the solver, the output contains the following information:

```

-----
The FULLY ADVANCED example RCI FGMRES with ILUT preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

```

Some info about the current run of RCI FGMRES method:

As IPAR(8)=0, the automatic test for the maximal number of iterations will be skipped

+++

As IPAR(9)=0, the automatic residual test will be skipped

+++

As IPAR(10)=1, the user-defined stopping test will be requested via RCI_REQUEST=2

+++

As IPAR(11)=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_REQUEST=3

+++

As IPAR(12)=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_REQUEST=4

+++

The system has been solved

The following solution has been obtained:

COMPUTED_SOLUTION(1)= 0.1000020E+01

COMPUTED_SOLUTION(2)= 0.1000007E+01

COMPUTED_SOLUTION(3)= 0.1000006E+01

COMPUTED_SOLUTION(4)= 0.9999908E+00

The expected solution is:

EXPECTED_SOLUTION(1)= 0.1000000E+01

EXPECTED_SOLUTION(2)= 0.1000000E+01

EXPECTED_SOLUTION(3)= 0.1000000E+01

EXPECTED_SOLUTION(4)= 0.1000000E+01

Number of iterations: 4

```
-----
Fortran example of FGMRES with ILUT preconditioner
has successfully PASSED all stages of computations
-----
```

NOTE. If the ILUT preconditioner is not used, then the same code requires 10 iterations.

Example C-39. Fortran Example to Solve Non-symmetric Non-degenerate Linear System

C Example of Using ILUT Preconditioner with RCI FGMRES Solver

C example has the same non-degenerate system as in the previous FORTRAN 77 example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example we adjust the addresses for input/result for user-defined operations from IPAR(22) to *ipar[21]-1* and from IPAR(23) to *ipar[22]-1*, respectively. Specific to ILUT preconditioner parameter entries are referred to as *ipar[30]*, *dpar[30]*, *dpar[31]*. Upon successful execution of the solver, the following information is printed (up to rounding errors that depend on the computer system):

```
-----
The FULLY ADVANCED example RCI FGMRES with ILUT
preconditioner to solve
the non-degenerate algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As ipar[7]=0, the automatic test for the maximal number of iterations will be
skipped
+++
As ipar[8]=0, the automatic residual test will be skipped
+++
As ipar[9]=1, the user-defined stopping test will be requested via
RCI_request=2
+++
As ipar[10]=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_request=3
+++
As ipar[11]=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_request=4
+++

The system has been solved

The following solution has been obtained:
computed_solution[0]=1.000020e+00
computed_solution[1]=1.000007e+00
computed_solution[2]=1.000006e+00
computed_solution[3]=9.999908e-01

The expected solution is:
expected_solution[0]=1.000000e+00
expected_solution[1]=1.000000e+00
expected_solution[2]=1.000000e+00
expected_solution[3]=1.000000e+00
```

Number of iterations: 4

```
-----
C example of FGMRES with ILUT preconditioner
has successfully PASSED all stages of computations
-----
```

NOTE. If the ILUT preconditioner is not used, then the same code requires 10 iterations.

Example C-40. C Example to Solve Non-symmetric Non-degenerate Linear System

Code Examples for Sparse Matrix Converters

This section contains code examples in FORTRAN 77 and C. For description of the sparse matrix converter routines used in these codes, refer to [Sparse Matrix Converters](#) in Chapter 2.

Example C-41. FORTRAN 77 Example for Sparse Matrix Converters

CBLAS Interface to the BLAS

This appendix presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

Similar to BLAS, the CBLAS interface includes the following levels of functions:

- “Level 1 CBLAS” (vector-vector operations)
- “Level 2 CBLAS” (matrix-vector operations)
- “Level 3 CBLAS” (matrix-matrix operations).
- “Sparse CBLAS” (operations on sparse vectors).

To obtain the C interface, the Fortran routine names are prefixed with `cblas_` (for example, `dasum` becomes `cblas_dasum`). Names of all CBLAS functions are in lowercase letters.

Complex functions `?dotc` and `?dotu` become CBLAS subroutines (void functions); they return the complex result via a void pointer, added as the last parameter. CBLAS names of these functions are suffixed with `_sub`. For example, the BLAS function `cdotc` corresponds to `cblas_cdotc_sub`.

WARNING. Users of the CBLAS interface should be aware that the CBLAS are just a C interface to the BLAS, which is based on the FORTRAN standard and subject to the FORTRAN standard restrictions. In particular, the output parameters should not be referenced through more than one argument.

In the descriptions of CBLAS interfaces, links provided for each function group lead to the descriptions of the respective Fortran-interface BLAS functions.

CBLAS Arguments

The arguments of CBLAS functions obey the following rules:

- Input arguments are declared with the `const` modifier.
- Non-complex scalar input arguments are passed by value.
- Complex scalar input arguments are passed as void pointers.
- Array arguments are passed by address.
- BLAS character arguments are replaced by the appropriate enumerated type.

- Level 2 and Level 3 routines acquire an additional parameter of type `CBLAS_ORDER` as their first argument. This parameter specifies whether two-dimensional arrays are row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

Enumerated Types

The CBLAS interface uses the following enumerated types:

```
enum CBLAS_ORDER {
    CblasRowMajor=101, /* row-major arrays */
    CblasColMajor=102}; /* column-major arrays */
enum CBLAS_TRANSPOSE {
    CblasNoTrans=111, /* trans='N' */
    CblasTrans=112, /* trans='T' */
    CblasConjTrans=113}; /* trans='C' */
enum CBLAS_UPLO {
    CblasUpper=121, /* uplo='U' */
    CblasLower=122}; /* uplo='L' */
enum CBLAS_DIAG {
    CblasNonUnit=131, /* diag='N' */
    CblasUnit=132}; /* diag='U' */
enum CBLAS_SIDE {
    CblasLeft=141, /* side='L' */
    CblasRight=142}; /* side='R' */
```

Level 1 CBLAS

This is an interface to “[BLAS Level 1 Routines and Functions](#)”, which perform basic vector-vector operations.

?asum

```
float cblas_sasum(const int N, const float *X, const int incX);
double cblas_dasum(const int N, const double *X, const int incX);
float cblas_scasum(const int N, const void *X, const int incX);
double cblas_dzasum(const int N, const void *X, const int incX);
```

?axpy

```
void cblas_saxpy(const int N, const float alpha, const float *X, const int incX, float *Y,
    const int incY);
void cblas_daxpy(const int N, const double alpha, const double *X, const int incX, double
    *Y, const int incY);
void cblas_caxpy(const int N, const void *alpha, const void *X, const int incX, void *Y,
```

```
const int incY);  
void cblas_zaxpy(const int N, const void *alpha, const void *X, const int incX, void *Y,  
const int incY);
```

?copy

```
void cblas_scopy(const int N, const float *X, const int incX, float *Y, const int incY);  
void cblas_dcopy(const int N, const double *X, const int incX, double *Y, const int incY);  
void cblas_ccopy(const int N, const void *X, const int incX, void *Y, const int incY);  
void cblas_zcopy(const int N, const void *X, const int incX, void *Y, const int incY);
```

?dot

```
float cblas_sdot(const int N, const float *X, const int incX, const float *Y, const int  
incY);  
double cblas_ddot(const int N, const double *X, const int incX, const double *Y, const int  
incY);
```

?sdot

```
float cblas_sdsdot(const int N, const float *SB, const float *SX, const int incX, const  
float *SY, const int incY);  
double cblas_dsdot(const int N, const float *SX, const int incX, const float *SY, const int  
incY);
```

?dotc

```
void cblas_cdotc_sub(const int N, const void *X, const int incX, const void *Y, const int  
incY, void *dotc);  
void cblas_zdotc_sub(const int N, const void *X, const int incX, const void *Y, const int  
incY, void *dotc);
```

?dotu

```
void cblas_cdotu_sub(const int N, const void *X, const int incX, const void *Y, const int  
incY, void *dotu);  
void cblas_zdotu_sub(const int N, const void *X, const int incX, const void *Y, const int  
incY, void *dotu);
```

?nrm2

```
float cblas_snorm2(const int N, const float *X, const int incX);
double cblas_dnorm2(const int N, const double *X, const int incX);
float cblas_scnrm2(const int N, const void *X, const int incX);
double cblas_dznrm2(const int N, const void *X, const int incX);
```

?rot

```
void cblas_srot(const int N, float *X, const int incX, float *Y, const int incY, const float
    c, const float s);
void cblas_drot(const int N, double *X, const int incX, double *Y, const int incY, const
    double c, const double s);
```

?rotg

```
void cblas_srotg(float *a, float *b, float *c, float *s);
void cblas_drotg(double *a, double *b, double *c, double *s);
```

?rotm

```
void cblas_srotm(const int N, float *X, const int incX, float *Y, const int incY, const
    float *P);
void cblas_drotm(const int N, double *X, const int incX, double *Y, const int incY, const
    double *P);
```

?rotmg

```
void cblas_srotmg(float *d1, float *d2, float *b1, const float b2, float *P);
void cblas_drotmg(double *d1, double *d2, double *b1, const double b2, double *P);
```

?scal

```
void cblas_sscal(const int N, const float alpha, float *X, const int incX);
void cblas_dscal(const int N, const double alpha, double *X, const int incX);
void cblas_cscal(const int N, const void *alpha, void *X, const int incX);
void cblas_zscal(const int N, const void *alpha, void *X, const int incX);
void cblas_csscal(const int N, const float alpha, void *X, const int incX);
void cblas_zdscal(const int N, const double alpha, void *X, const int incX);
```

?swap

```
void cblas_sswap(const int N, float *X, const int incX, float *Y, const int incY);
void cblas_dswap(const int N, double *X, const int incX, double *Y, const int incY);
void cblas_cswap(const int N, void *X, const int incX, void *Y, const int incY);
void cblas_zswap(const int N, void *X, const int incX, void *Y, const int incY);
```

i?amax

```
CBLAS_INDEX cblas_isamax(const int N, const float *X, const int incX);
CBLAS_INDEX cblas_idamax(const int N, const double *X, const int incX);
CBLAS_INDEX cblas_icamax(const int N, const void *X, const int incX);
CBLAS_INDEX cblas_izamax(const int N, const void *X, const int incX);
```

i?amin

```
CBLAS_INDEX cblas_isamin(const int N, const float *X, const int incX);
CBLAS_INDEX cblas_idamin(const int N, const double *X, const int incX);
CBLAS_INDEX cblas_icamin(const int N, const void *X, const int incX);
CBLAS_INDEX cblas_izamin(const int N, const void *X, const int incX);
```

Level 2 CBLAS

This is an interface to “BLAS Level 2 Routines”, which perform basic matrix-vector operations. Each C routine in this group has an additional parameter of type `CBLAS_ORDER` (the first argument) that determines whether the two-dimensional arrays use column-major or row-major storage.

?gbmv

```
void cblas_sgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const int N, const int KL, const int KU, const float alpha, const float *A, const int lda, const float *X, const int incX, const float beta, float *Y, const int incY);
void cblas_dgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const int N, const int KL, const int KU, const double alpha, const double *A, const int lda, const double *X, const int incX, const double beta, double *Y, const int incY);
void cblas_cgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const int N, const int KL, const int KU, const void *alpha, const void *A, const int lda, const void *X, const int incX, const void *beta, void *Y, const int incY);
void cblas_zgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const int N, const int KL, const int KU, const void *alpha, const void *A, const int lda, const void *X, const int incX, const void *beta, void *Y, const int incY);
```

?gemv

```
void cblas_sgemv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int
M, const int N, const float alpha, const float *A, const int lda, const float *X, const
int incX, const float beta, float *Y, const int incY);

Sparse CBLAS

This is an interface to “[Sparse BLAS Level 1 Routines and Functions](#)”, which perform a number of common vector operations on sparse vectors stored in compressed form.

Note that all index parameters, *indx*, are in C-type notation and vary in the range [0..N-1].

?axpyi

```
void cblas_saxpyi(const int N, const float alpha, const float *X, const int *indx, float
*Y);
void cblas_daxpyi(const int N, const double alpha, const double *X, const int *indx, double
*Y);
void cblas_caxpyi(const int N, const void *alpha, const void *X, const int *indx, void *Y);
void cblas_zaxpyi(const int N, const void *alpha, const void *X, const int *indx, void *Y);
```

?doti

```
float cblas_sdoti(const int N, const float *X, const int *indx, const float *Y);
double cblas_ddoti(const int N, const double *X, const int *indx, const double *Y);
```

?dotci

```
void cblas_cdotci_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
void cblas_zdotci_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
```

?dotui

```
void cblas_cdotui_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
void cblas_zdotui_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
```

?gthr

```
void cblas_sgthr(const int N, const float *Y, float *X, const int *indx);
void cblas_dgthr(const int N, const double *Y, double *X, const int *indx);
void cblas_cgthr(const int N, const void *Y, void *X, const int *indx);
void cblas_zgthr(const int N, const void *Y, void *X, const int *indx);
```

?gthrz

```

void cblas_csctr(const int N, const void *X, const int *indx, void *Y);
void cblas_zsctr(const int N, const void *X, const int *indx, void *Y);
```

Specific Features of Fortran 95 Interfaces for LAPACK Routines

Intel® MKL implements Fortran 95 interface for LAPACK package, further referred to as MKL LAPACK95, to provide full capacity of MKL FORTRAN 77 LAPACK routines. This is the principal difference of Intel MKL from the Netlib Fortran 95 implementation for LAPACK.

A new feature of MKL LAPACK95 by comparison with Intel MKL LAPACK77 implementation is presenting a package of source interfaces along with wrappers that make the implementation compiler-independent. As a result, the MKL LAPACK package can be used in all programming environments intended for Fortran 95.

Depending on the degree and type of difference from Netlib implementation, the MKL LAPACK95 interfaces fall into several groups that require different transformations (see [“MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation”](#)). The groups are given in full with the calling sequences of the routines and appropriate differences from Netlib analogs.

The following conventions are used:

```
<interface> ::= <name of interface> '(' <arguments list> ')'  
<arguments list> ::= <first argument> {<argument>}*  
<first argument> ::= <identifier>  
<argument> ::= <required argument> | <optional argument>  
<required argument> ::= '[' <identifier>  
<optional argument> ::= '[' , <identifier> ']'  
<name of interface> ::= <identifier>
```

where defined notions are separated from definitions by `::=`, notion names are marked by angle brackets, terminals are given in quotes, and `{...}`* denotes repetition zero, one, or more times.

`<first argument>` and each `<required argument>` should be present in all calls of denoted interface, `<optional argument>` may be omitted. Comments to interface definitions are provided where necessary. Comment lines begin with character `!`.

Two interfaces with one name are presented when two variants of subroutine calls (separated by types of arguments) exist.

Interfaces Identical to Netlib

Optimization Solvers Basics

Classical optimization methods are linear methods based on calculation of a direction and search for the best point in the direction of the chosen gradient. The direction is calculated for each iteration. Examples of these methods are Conjugate Gradients and Quickest Descent. The search method usually requires calculation of the objective function approximation in a neighborhood of the current point.

Optimization problems generally have three basic components:

- An *objective function* that needs to be minimized or maximized. For instance, in a manufacturing process, you might want to maximize the profit or minimize the cost. In fitting experimental data to a user-defined model, the total deviation of observed data can be minimized from predictions based on the model.
- A set of *unknowns* or *variables* that affect the value of the objective function. In the manufacturing problem, the variables might include the amount of resources used or the time spent on each activity. In fitting-the-data problem, the unknowns are the parameters that define the model.
- A set of *constraints* that allow unknowns to take on certain values but exclude others. In the manufacturing problem, it does not make sense to spend a negative amount of time on any activity, so all the "time" variables are constrained to be non-negative.

The overall goal is to *find values of the variables that minimize or maximize the objective function while meeting the constraints*.

Intel® MKL provides math optimization tools, namely the optimized Trust-Region (TR) solvers for nonlinear least squares problems with or without linear constraints.

Nonlinear Least Squares Problem

Nonlinear least squares problem can be described as follows:

$$\min_{x \in \mathbb{R}^n} F(x) = \|y - f(x)\|_2^2, \quad y \in \mathbb{R}^m, \quad x \in \mathbb{R}^n, \quad f: \mathbb{R}^n \rightarrow \mathbb{R}^m, \quad m > n,$$

where $F(x) : \mathbb{R}^n \rightarrow \mathbb{R}$ is a twice differentiable function in \mathbb{R}^n . Solving of nonlinear least squares problem is searching for the best approximation to vector y with the model function that has nonlinear dependence on variables x . Best approximation means that the sum of squares of residuals is the lowest possible.

If

$$F(x) = \sum_{i=1}^m r_i(x)^2, \quad r_i(x) = y_i - f_i(x),$$

then

$$F(x) = \frac{1}{2} R(x)^T R(x),$$

where $R(x) = \{ r_i(x) \}, i = 1, \dots, m$.

Trust-Region Algorithm

The Trust-Region (TR) algorithms are relatively new iterative methods for solving nonlinear optimization problems. They are widely used in power engineering, finance, applied mathematics, physics, computer science, economics, sociology, biology, medicine, mechanical engineering, chemistry, and other areas. The TR methods have global convergence and local super convergence, which differentiates them from line search methods and Newton methods. The TR methods have better convergence when compared with widely-used Newton-like methods.

The main idea behind a TR algorithm is calculating a trial step and checking if the next values of x_+ belong to the *trust region* [Conn00]. Calculation of the trial step is strongly associated with the approximation model.

If the nonlinear least squares problem is defined as

$$\min_{x \in \mathbb{R}^n} F(x) = \|y - f(x)\|_2^2, \quad y \in \mathbb{R}^m, \quad x \in \mathbb{R}^n, \quad f: \mathbb{R}^n \rightarrow \mathbb{R}^m, \quad m > n,$$

then the trial step is a solution of the following subproblem:

$$\min_{d \in \mathbb{R}^n} \|F(x_k) + J(x_k)^T d\|_2^2, \quad \text{where } \|d\|_2^2 < \Delta_k \quad \text{and } J(x_k) \text{ is Jacobi matrix.}$$

This operation is an approximation to the objective function in a neighborhood of the current point x .

Consider a TR algorithm with **linear (bound) constraints** :

$$\min_{l \leq x \leq u} f(x) = \min_{l \leq x \leq u} \frac{1}{2} \|F(x)\|^2.$$

The first-order necessary condition for the vector to be minimized with this constraint is

$$D(x)^{-2} \nabla f(x) = D(x)^{-2} F'^T(x) F(x) = 0,$$

where D is the diagonal scaling matrix

$$D(x) = \text{diag}\left(\left|v_1^{-\frac{1}{2}}(x)\right|, \left|v_2^{-\frac{1}{2}}(x)\right|, \dots, \left|v_n^{-\frac{1}{2}}(x)\right|\right)$$

with

$$v_i(x) = \begin{cases} x_i - u_i & \text{if } \nabla f(x)_i < 0 \text{ and } u_i < \infty \\ x_i - l_i & \text{if } \nabla f(x)_i > 0 \text{ and } l_i < \infty \\ \min(x_i - u_i, u_i - x_i) & \text{if } \nabla f(x)_i = 0 \text{ and } u_i < \infty \text{ or } l_i > -\infty \\ -1 & \text{if } \nabla f(x)_i < 0 \text{ and } u_i = \infty \\ 1 & \text{if } \nabla f(x)_i < 0 \text{ and } u_i = \infty \\ 1 & \text{if } \nabla f(x)_i = 0 \text{ and } u_i = -l_i = \infty \end{cases}$$

for $i = 1, \dots, n$.

Provided $\Omega = \{x \in \mathbb{R}^n: l \leq x \leq u\} \subset \mathbb{R}^n$, write $\text{int}(\Omega)$ for the strictly nonempty interior of Ω . At each iteration, the basic structure of the method involves solving an elliptical trust-region subproblem and computing a search step to update the current iteration.

Provided $x_i \in \text{int}(\Omega)$ and the trust region size $\Delta_k > 0$, consider the elliptical trust-region subproblem

$$\min_p \left\{ F(x_k) + J(x_k)^T p : \|D_k p\| \leq \Delta_k \right\}.$$

Let $p_{tr}(\Delta_k)$ and $p_c(\Delta_k)$ be a solution and a Cauchy point of the above trust-region subproblem respectively [Conn00]. The following linear combination of two vectors $p_{tr}(\Delta_k)$ and $p_c(\Delta_k)$ defines the search step (trial step) used in the algorithm, that is,

$$p(\Delta_k) = t \bar{p}_c(\Delta_k) + (1-t) \bar{p}_{tr}(\Delta_k).$$

A good agreement between the model function m_k and the objective function f is ensured for the following standard condition:

$$\rho_f(p(\Delta_k)) = \frac{f(x_k) - f(x_k + p(\Delta_k))}{m_k(0) - m_k(p_k(\Delta_k))} \geq \beta_2$$

with the given constant $\beta_2 \in (0,1)$. If this condition is not met, reject $p(\Delta_k)$, and the trust-region size Δ_k is successively reduced so that $p(\Delta_k)$ satisfies the accuracy requirement.

FFTW to Intel® Math Kernel Library Wrappers

Intel® Math Kernel Library (Intel® MKL) offers two collections of wrappers being the FFTW interface (www.fftw.org) superstructure to be used for calling the Intel MKL Fourier transform functions.

The purpose of these wrappers is to enable developers whose programs currently use FFTW to gain performance with the Intel MKL Fourier transforms without changing the program source code.

Notational Conventions

This appendix typically employs path notations for the Windows* OS.

FFTW2.x to Intel® Math Kernel Library Wrappers

This section describes a collection of wrappers being the FFTW interfaces superstructure to be used for calling functions of the Intel MKL Fourier transform interface (FFT interface). The wrappers correspond to FFTW 2.x and the Intel MKL versions 7.0 or higher.

Because of differences between FFTW and Intel MKL FFT functionalities, there are restrictions on using wrappers instead of the FTTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Please refer to [chapter 11 "Fourier Transform Functions"](#), for better understanding the effects from the use of the wrappers.

Additional wrappers may be added in the future to extend FFTW functionality available with Intel MKL.

Wrappers Reference

The section provides a reference for FFTW C interface.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed below, are empty and do nothing, but they are still needed to avoid link errors and satisfy the function calls. Intel MKL FFT interface operates on both float and double-precision data types.

Complex Fast Fourier Transforms

One-dimensional FFTs

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);

fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int
idist, fftw_complex *out, int ostride, int odist);

void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Multi-dimensional FFTs

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir,
int flags);

fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);

fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir,
int flags);

fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction
dir, int flags, fftw_complex *in, int istride, fftw_complex *out, int
ostride);

fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir,
int flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);

fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction
dir, int flags, fftw_complex *in, int istride, fftw_complex *out, int
ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride,
int idist, fftw_complex *out, int ostride, int odist);

void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);

void fftwnd_destroy_plan(fftwnd_plan plan);
```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Real Fast Fourier Transforms

One-dimensional FFTs

All wrappers are empty and do nothing, as the Intel MKL FFT interface does not currently support this functionality (halfcomplex array).

Multi-dimensional FFTs

```

rfftwnd_plan rfftwnd_create_plan(int rank, const int *n, fftw_direction dir,
int flags);

rfftwnd_plan rfftw2d_create_plan(int nx, int ny, fftw_direction dir, int
flags);

rfftwnd_plan rfftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir,
int flags);

void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in,
int istride, int idist, fftw_complex *out, int ostride, int odist);

void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex
*in, int istride, int idist, fftw_real *out, int ostride, int odist);

void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in,
fftw_complex *out);

void rfftwnd_one_complex_to_real(rfftwnd_plan plan, fftw_complex *in,
fftw_real *out);

void rfftwnd_destroy_plan(rfftwnd_plan plan);

```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Wisdom Wrappers

All wrappers are empty and do nothing, because the Intel MKL FFT interface currently does not support these functionalities.

Memory Allocation

```
void* fftw_malloc(size_t n);
```

```
void fftw_free(void* x);
```

Unlike the `fftw_malloc` function, the `fftw_malloc` wrapper does not align the allocatable array. To do that, it is necessary to allocate extra memory and shift the array address for the FFT data. See also the *"Managing Performance and Memory" chapter in the Intel MKL User's Guide* (file `userguide.pdf`).

Parallel Mode

This section touches upon multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel MKL for the Linux* and Windows* operating systems, are described in [section "MPI FFTW Wrappers"](#).

Multi-threaded FFTW

FFTW multi-threaded functions use the *number of threads* parameter, which the `fftw_threads_init` function defines. However, the `int fftw_threads_init(void)` wrapper is empty and does nothing, because the Intel MKL FFT interface implements a different mechanism of parallelization. If you want to use Intel MKL FFT routines in a parallel mode or call wrappers from a multi-threaded application, please refer to [the "Number of User Threads" section in chapter 11](#) to learn how to manage the number of threads.

Each of the remaining wrappers in this section is the same as the respective wrapper in [section Complex Fast Fourier Transforms](#) or [Real Fast Fourier Transforms](#) whose name differs from the one of the given wrapper in cutting out `'threads_'`.

For example,

```
void fftw_threads_one(int threads, fftw_plan plan, fftw_complex *in,
fftw_complex *out);
```

is the same as

```
void fftw_one(fftw_plan plan, fftw_complex *in, fftw_complex *out);
```

Argument restrictions. The *threads* parameter is inessential. Both functions may be single-threaded or parallel depending on Intel MKL variables.

Calling Wrappers from Fortran

Wrappers are available for all Fortran FFTW functions. For example, instead of calling the C wrapper `fftw_one`, in Fortran, you should call the `fftw_f77_one` wrapper.

FFTW Fortran functions are actually the wrappers to FFTW C functions. Fortran wrappers are actually the wrappers to C wrappers. So, their functionality and argument restrictions are the same as of the corresponding C wrappers.

Installation

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers and makefiles with the wrapper list files are located in the `.\interfaces\fftw2xc` and `.\interfaces\fftw2xf` subdirectory in the Intel MKL directory for C and Fortran wrappers, respectively.

Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the `.\interfaces\fftw2xc\wrappers` subdirectory in the Intel MKL directory.

Three header files are used to compile the Fortran wrapper library: `fftw2_mkl.h`, `fftw2_f77_mkl.h`, and `fftw.h`. The `fftw2_mkl.h` and `fftw2_f77_mkl.h` files are located in the `.\interfaces\fftw2xf\wrappers` subdirectory in the Intel MKL directory.

The file `fftw.h`, used to compile libraries for both interfaces and located in the `.\include\fftw` subdirectory in the Intel MKL directory, slightly differs from the original FFTW (www.fftw.org) header file `fftw.h`.

A wrapper library contains C and Fortran wrappers for complex and real transforms in a serial and multi-threaded mode for one of the two data types (`double` or `float`). A makefile parameter manages the data type.

The makefile parameters specify the platform, compiler, precision, and function. The makefile comment heading provides the description of these parameters.

Specifying the platform is required. Possible values:

- `lib32` — 32-bit applications
- `libem64t` — Intel® 64 architecture based applications
- `lib64` — IA-64 architecture based applications.

The rest of parameters have default values and are optional.

The parameter `compiler` (on the Linux* OS and Mac OS* X)/`COMPILER` (on the Windows* OS) may have values:

- `intel` — Intel® compilers version 9.1 or higher, default

- `gnu` — GNU* compiler on the Linux* OS and Mac OS* X
- `mc` — Microsoft Visual C++* Compiler on the Windows* OS.

The parameter `PRECISION` may have values:

- `MKL_DOUBLE` — double-precision data, default
- `MKL_SINGLE` — float, single-precision data.

The parameter `function` is not used for building a wrapper library.

As a C compiler builds the Fortran wrapper library, function names in the wrapper library and Fortran object module may be different. The file `fftw2_f77_mkl.h` in the `.\interfaces\fftw2xf\source` subdirectory in the Intel MKL directory defines function names according to names in the Fortran module. If a required name is missing in the file, you can modify the file to add the name.

Examples

The command

```
make lib64
```

builds a double-precision wrapper library for IA-64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler version 9.1 or higher (Compilers and `PRECISION=MKL_DOUBLE` are chosen by default.).

The command

```
make lib64 PRECISION=MKL_SINGLE
```

builds a single-precision wrapper library for IA-64 architecture based applications using the Intel C++ Compiler or the Intel Fortran Compiler version 9.1 or higher (Compilers are chosen by default.).

As a result, the wrapper library will be created in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/64` (on the Linux* OS and Mac OS* X) or `.\ia32\lib` (on the Windows* OS).

In the wrapper library names, the suffix corresponds to the used compiler and the underscore is preceded with letter "f" for Fortran and "c" for C.

For example,

`fftw2xf_intel.lib` (on the Windows OS); `libfftw2xf_intel.a` (on the Linux OS and Mac OS X);

`fftw2xc_intel.lib` (on the Windows OS); `libfftw2xc_intel.a` (on the Linux OS and Mac OS X);

`fftw2xc_ms.lib` (on the Windows OS); `libfftw2xc_gnu.a` (on the Linux OS and Mac OS X).

Application Assembling

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw2xc` and `.\examples\fftw2xf` subdirectories in the Intel MKL directory for C and Fortran, respectively. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, `rfftw_threads.h`, and `fftw_f77.i`. These files are distributed with permission from FFTW and are available in `.\include\fftw`. The original files can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefiles comment heading and are the same as the wrapper library makefile parameters (see [Creating a Wrapper Library](#)). Example makefiles normally invoke examples. However, if the appropriate wrapper library is not yet created, the makefile will first build it in the same way as the wrapper library makefile does and then proceed to examples.

If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples from the appropriate subdirectory will run. The subdirectory `._results` will be created, and the results will be stored there in the `<example_name>.res` files.

MPI FFTW

MPI FFTW wrappers are available only with Intel® MKL for the Linux* and Windows* operating systems.

MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

Complex MPI FFTW

Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir,  
int flags);
```

```
void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data,
fftw_complex *work);

void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start,
int *local_n_after_transform, int *local_start_after_transform, int
*total_local_size);

void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE, FFTW_MEASURE, FFTW_SCRAMBLED_INPUT and FFTW_SCRAMBLED_OUTPUT. The same algorithm corresponds to all these values of the flags parameter. If any other *flags* value is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n_fields* is 1.

Complex Multi-dimensional MPI FFTW Transforms

```
fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny,
fftw_direction dir, int flags);

fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int
nz, fftw_direction dir, int flags);

fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n,
fftw_direction dir, int flags);

void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data,
fftw_complex *work, fftwnd_mpi_output_order output_order );

void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int
*local_x_start, int *local_ny_after_transpose, int
*local_y_start_after_transpose, int *total_local_size);

void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *output_order* is FFTW_NORMAL_ORDER. If any other value of *output_order* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown output_order'.

- The only supported value of `n_fields` is 1.

Real MPI FFTW

Real Multi-dimensional MPI FFTW Transforms

The wrappers are empty and do nothing. If the wrappers are used, the wrapper library reports an error '*CDFT error in wrapper*'.

Creating MPI FFTW Wrapper Library

The source code for the wrappers and makefiles with the wrapper list files are located in the `.\interfaces\fftw2x_cdft` subdirectory in the Intel MKL directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see [MPI FFTW Wrappers Reference](#).

Makefile parameters specify the platform, compiler, precision, MPI version, and MPI directory. The makefile comment heading provides description of these parameters.

Specifying the platform is required. Possible values:

- `lib32` — 32-bit applications
- `libem64t` — Intel® 64 architecture based applications
- `lib64` — IA-64 architecture based applications.

The value of the parameter `mpidir` is the path to the MPI installation directory. If this directory is in the `PATH` system variable, you can omit the parameter.

The rest of the parameters are optional as well and have default values.

The parameter `compiler` may have values:

- `intel` — Intel® compilers version 9.1 or higher on the Linux* OS, default
- `gnu` — GNU* compiler on the Linux OS.

On the Windows* OS, this parameter is not used. The default Intel® compiler will be used to build the library.

The parameter `PRECISION` may have values:

- `MKL_DOUBLE` — double-precision data, default
- `MKL_SINGLE` — float, single-precision data.

The parameter `mpispecifies` the MPI library to be used. The parameter may have values:

- `intel` — Intel® MPI 2.0 or higher on the Linux OS; default for the Linux OS
- `mpich` — MPICH 1.2.x on the Linux OS
- `mpich2` — MPICH2 1.0.x on the Linux or Windows* OS; default for the Windows OS
- `msmpi` — Microsoft* MPI library on the Windows OS (for the Intel® 64 architecture only).

Examples

The command

```
make lib64
```

builds a double-precision wrapper library for IA-64 architecture based applications using Intel MPI 2.0 and the Intel® C++ Compiler version 9.1 or higher on the Linux OS (Compilers and `PRECISION=MKL_DOUBLE` are chosen by default.).

The command

```
make lib32 mpi=mpich PRECISION=MKL_SINGLE
```

builds a single-precision wrapper library for the 32-bit applications using MPICH 1.2.x and the Intel C++ Compiler version 9.1 or higher on the Linux OS (Compilers are chosen by default.).

As a result, the wrapper library will be created in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/64` (on the Linux* OS) or `.\ia32\lib` (on the Windows* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

`fftw2x_cdft_SINGLE.lib` on the Windows OS;

`libfftw2x_cdft_DOUBLE.a` on the Linux OS.

Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library. The source C code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw2x_cdft` subdirectory in the Intel MKL directory. To build examples, one additional file `fftw_mpi.h` is needed. This file is distributed with permission from FFTW and is available in `.\include\fftw`. The original file can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefile comment headings and are the same as the wrapper library makefile parameters (see [Creating MPI FFTW Wrapper Library](#)) except for `PRECISION`, which takes different values:

- `FFTW_ENABLE_DOUBLE` — double-precision data, default
- `FFTW_ENABLE_FLOAT` — float, single-precision data.

The table below lists examples available in the `.\examples\fftw2x_cdft\source` subdirectory.

Table G-1 Examples of MPI FFTW Wrappers

Source file for the example	Description
<code>wrappers_c1d.c</code>	One-dimensional Complex MPI FFTW transform, using <code>plan = fftw_mpi_create_plan(...)</code>
<code>wrappers_c2d.c</code>	Two-dimensional Complex MPI FFTW transform, using <code>plan = fftw2d_mpi_create_plan(...)</code>
<code>wrappers_c3d.c</code>	Three-dimensional Complex MPI FFTW transform, using <code>plan = fftw3d_mpi_create_plan(...)</code>
<code>wrappers_c4d.c</code>	Four-dimensional Complex MPI FFTW transform, using <code>plan = fftwnd_mpi_create_plan(...)</code>

FFTW3.x to Intel® Math Kernel Library Wrappers

This section describes a collection of wrappers being the FFTW interfaces superstructure to be used for calling functions of the Intel MKL Fourier transform (FFT) or Trigonometric Transform (TT) interface. These wrappers correspond to FFTW 3.x and the Intel MKL versions 7.0 or higher.

The purpose of this set of wrappers is to enable developers whose programs currently use FFTW to gain performance with the Intel MKL Fourier transforms without changing the program source code. The only change that is required is to modify the header file `fftw3.h` (see [Creating a Wrapper Library](#)). Because of differences between FFTW and Intel MKL FFT/TT functionalities, there are a lot of restrictions on using wrappers instead of FTTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Please refer to [chapter 11 "Fourier Transform Functions"](#), and [section "Trigonometric Transform Routines"](#), for better understanding the effects from the use of the wrappers.

Additional wrappers may be added in the future to extend FFTW functionality available with Intel MKL.

Wrappers Reference

The section provides a reference for FFTW C interface.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed below, are empty and do nothing, but they are still needed to avoid link errors and satisfy the function calls.

Note that the Intel MKL FFT functions operate on `float` and `double-precision` data types and do not support the `long-double` data type used by the FFTW functions.

Wrappers for Using Plans

```
void fftw_execute(const fftw_plan plan);  
void fftw_destroy_plan(const fftw_plan plan);  
void fftwf_execute(const fftw_plan plan);  
void fftwf_destroy_plan(const fftw_plan plan);
```

Basic Interface Wrappers

Wrappers for execution and plan destruction functions are listed in [Wrappers for Using Plans](#).

Complex DFTs

```
fftw_plan fftw_plan_dft_1d(int n, fftw_complex *in, fftw_complex *out, int
sign, unsigned flags);

fftw_plan fftw_plan_dft_2d(int nx, int ny, fftw_complex *in, fftw_complex
*out, int sign, unsigned flags);

fftw_plan fftw_plan_dft_3d(int nx, int ny, int nz, fftw_complex *in,
fftw_complex *out, int sign, unsigned flags);

fftw_plan fftw_plan_dft(int rank, const int *n, fftw_complex *in, fftw_complex
*out, int sign, unsigned flags);

fftwf_plan fftwf_plan_dft_1d(int n, fftwf_complex *in, fftwf_complex *out,
int sign, unsigned flags);

fftwf_plan fftwf_plan_dft_2d(int nx, int ny, fftwf_complex *in, fftwf_complex
*out, int sign, unsigned flags);

fftwf_plan fftwf_plan_dft_3d(int nx, int ny, int nz, fftwf_complex *in,
fftwf_complex *out, int sign, unsigned flags);

fftwf_plan fftwf_plan_dft(int rank, const int *n, fftwf_complex *in,
fftwf_complex *out, int sign, unsigned flags);
```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Real-Data DFTs

```
fftw_plan fftw_plan_dft_r2c(int rank, const int *n, double *in, fftw_complex
*out, unsigned flags);

fftw_plan fftw_plan_dft_r2c_1d(int n, double *in, fftw_complex *out, unsigned
flags);

fftw_plan fftw_plan_dft_r2c_2d(int nx, int ny, double *in, fftw_complex *out,
unsigned flags);

fftw_plan fftw_plan_dft_r2c_3d(int nx, int ny, int nz, double *in,
fftw_complex *out, unsigned flags);
```

```
fftw_plan fftw_plan_dft_c2r(int rank, const int *n, fftw_complex *in, double
*out, unsigned flags);

fftw_plan fftw_plan_dft_c2r_1d(int n, fftw_complex *in, double *out, unsigned
flags);

fftw_plan fftw_plan_dft_c2r_2d(int nx, int ny, fftw_complex *in, double *out,
unsigned flags);

fftw_plan fftw_plan_dft_c2r_3d(int nx, int ny, int nz, fftw_complex *in,
double *out, unsigned flags);

fftwf_plan fftwf_plan_dft_r2c(int rank, const int *n, float *in, fftwf_complex
*out, unsigned flags);

fftwf_plan fftwf_plan_dft_r2c_1d(int n, float *in, fftwf_complex *out,
unsigned flags);

fftwf_plan fftwf_plan_dft_r2c_2d(int nx, int ny, float *in, fftwf_complex
*out, unsigned flags);

fftwf_plan fftwf_plan_dft_r2c_3d(int nx, int ny, int nz, float *in,
fftwf_complex *out, unsigned flags);

fftwf_plan fftwf_plan_dft_c2r(int rank, const int *n, fftwf_complex *in,
float *out, unsigned flags);

fftwf_plan fftwf_plan_dft_c2r_1d(int n, fftwf_complex *in, float *out,
unsigned flags);

fftwf_plan fftwf_plan_dft_c2r_2d(int nx, int ny, fftwf_complex *in, float
*out, unsigned flags);

fftwf_plan fftwf_plan_dft_c2r_3d(int nx, int ny, int nz, fftwf_complex *in,
float *out, unsigned flags);
```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Real-to-Real Transforms

Currently, only real 1D even/odd DFTs (cosine/sine transforms) are supported.

```
fftw_plan fftw_plan_r2r_1d(int n, double *in, double *out, fftw_r2r_kind
kind, unsigned flags);

fftw_plan fftwf_plan_r2r_1d(int n, float *in, float *out, fftw_r2r_kind kind,
unsigned flags);
```

Argument restrictions and extension:

- The same algorithm corresponds to all values of the *flags* parameter.
- A new value `MKL_RODFT00` of the *kind* parameter was introduced in the wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00` and provide input/output vectors that have an extra first element equal to 0.0. For example, let the input vector *in1* for the function

```
callplan1=fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
```

be (u, v, w) of length 3, then to accomplish the same transform with *kind* = `MKL_RODFT00`, that is, with the function

```
callplan1=fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

the input vector *in2* should be $(0.0, u, v, w)$ of length 4. Similarly, whereas the result *out1* is (x, y, z) , the result *out2* is $(0.0, x, y, z)$.

Advanced Interface Wrappers

Wrappers for execution and plan destruction functions are listed in [Wrappers for Using Plans](#).

Advanced Complex Discrete Fourier Transforms (DFTs)

```
fftw_plan fftw_plan_many_dft(int rank, const int *n, int howmany, fftw_complex
    *in, const int *inembed, int istride, int idist, fftw_complex *out, const
    int *onembed, int ostride, int odist, int sign, unsigned flags);
```

```
fftwf_plan fftwf_plan_many_dft(int rank, const int *n, int howmany,
    fftwf_complex *in, const int *inembed, int istride, int idist, fftwf_complex
    *out, const int *onembed, int ostride, int odist, int sign, unsigned flags);
```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Advanced Real-Data DFTs

```
fftw_plan fftw_plan_many_dft_r2c(int rank, const int *n, int howmany, double*
    in, const int *inembed, int istride, int idist, fftw_complex *out, const int
    *onembed, int ostride, int odist, unsigned flags);
```

```
fftwf_plan fftwf_plan_many_dft_r2c(int rank, const int *n, int howmany,
    float* in, const int *inembed, int istride, int idist, fftwf_complex *out,
    const int *onembed, int ostride, int odist, unsigned flags);
```

```
fftw_plan fftw_plan_many_dft_c2r(int rank, const int *n, int howmany,
fftw_complex* in, const int *inembed, int istride, int idist, double *out,
const int *onembed, int ostride, int odist, unsigned flags);

fftwf_plan fftwf_plan_many_dft_c2r(int rank, const int *n, int howmany,
fftwf_complex* in, const int *inembed, int istride, int idist, float *out,
const int *onembed, int ostride, int odist, unsigned flags);
```

Advanced Real-to-Real Transforms

All wrappers are empty and do nothing. The wrappers may be added in later versions of Intel MKL.

Guru Interface Wrappers

Guru Complex Discrete Fourier Transforms (DFTs)

```
fftw_plan fftw_plan_guru_dft(int rank, const fftw_iodim *dims, int
howmany_rank, const fftw_iodim *howmany_dims, fftw_complex *in, fftw_complex
*out, int sign, unsigned flags);

fftwf_plan fftwf_plan_guru_dft (int rank, const fftwf_iodim *dims, int
howmany_rank, const fftwf_iodim *howmany_dims, fftwf_complex *in,
fftwf_complex *out, int sign, unsigned flags);
```

Argument restrictions: The same algorithm corresponds to all values of the *flags* parameter. The only supported value of *howmany_rank* is 1.

The rest of the wrappers are empty and do nothing, because the Intel MKL FFT interface currently does not support split arrays.

Guru Real-Data DFTs

All wrappers are empty and do nothing.

Real-data wrappers (without support of split arrays) may be added in later versions of Intel MKL.

Guru Real-to-Real Transforms

All wrappers are empty and do nothing. The wrappers may be added in later versions of Intel MKL.

Guru Execution of Plans

```
void fftw_execute_dft(const fftw_plan p, fftw_complex *in, fftw_complex *out
);

void fftw_execute_dft_r2c(const fftw_plan p, double *in, fftw_complex *out);
void fftw_execute_dft_c2r(const fftw_plan p, fftw_complex *in, double *out);
void fftwf_execute_dft(const fftwf_plan p, fftwf_complex *in, fftwf_complex
*out);

void fftwf_execute_dft_r2c(const fftwf_plan p, float *in, fftwf_complex
*out);

void fftwf_execute_dft_c2r(const fftwf_plan p, fftwf_complex *in, float
*out);
```

The rest of the wrappers are empty and do nothing.

Real-data wrappers (without support of split arrays) will be added in later versions of Intel MKL.

Wrappers for more execution and plan destruction functions are listed in [Wrappers for Using Plans](#).

Wisdom Wrappers

All wrappers are empty and do nothing, as the Intel MKL FFT Interface currently does not support these functionalities.

Memory Allocation

```
void* fftw_malloc(size_t n);
void fftw_free(void* x);
void* fftwf_malloc(size_t n);
void fftwf_free(void* x);
```

Unlike the `fftw_malloc` and `fftwf_malloc` functions, the `fftw_malloc` and `fftwf_malloc` wrappers do not align the allocatable array. To do that, it is necessary to allocate extra memory and shift the array address for the FFT data. See also the *Managing Performance and Memory* chapter in the *Intel MKL User's Guide* (file `userguide.pdf`).

Parallel Mode

FFTW multi-threaded functions use the *number of threads* parameter, which the function `fftw_threads_init` defines and the function `fftw_plan_with_nthreads` sets. However, the wrappers to these functions and the `fftw_cleanup_threads` wrapper are empty and do nothing, because the Intel MKL FFT Interface implements a different mechanism of parallelization. If you want to use Intel MKL FFT routines in a parallel mode or call wrappers from a multi-threaded application, please refer to [the "Fourier Transform Functions" chapter](#) to learn how to manage the number of threads.

Calling Wrappers from Fortran

Wrappers are available for all the Fortran FFTW functions. FFTW Fortran functions are actually the wrappers to FFTW C functions. Fortran wrappers are actually the wrappers to C wrappers. So, their functionality and argument restrictions are the same as of the corresponding C wrappers.

```

Installation

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers and makefiles with the wrapper list files are located in the `.\interfaces\fftw3xc` and `.\interfaces\fftw3xf` subdirectories in the Intel MKL directory for C and Fortran wrappers, respectively.

Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw3_mkl.h` and `fftw3.h`. The `fftw3_mkl.h` file is located in the `.\interfaces\fftw3xc\wrappers` subdirectory in the Intel MKL directory.

Three header files are used to compile the Fortran wrapper library: `fftw3_mkl.h`, `fftw3_f77_mkl.h`, and `fftw3.h`. The `fftw3_mkl.h` and `fftw3_f77_mkl.h` files are located in the `.\interfaces\fftw3xf\wrappers` subdirectory in the Intel MKL directory.

The file `fftw3.h`, used to compile libraries for both interfaces and located in the `.\include\fftw` subdirectory in the Intel MKL directory, slightly differs from the original FFTW (www.fftw.org) header file `fftw3.h` in that all rows containing calls to the `fftw3.lib` are commented out.

As a C compiler builds the Fortran wrapper library, function names in the wrapper library and Fortran object module may be different. The file `fftw3_f77_mkl.h` in the `.\interfaces\fftw3xf\wrappers` subdirectory in the Intel MKL directory defines function names according to names in the Fortran module. If a required name is missing in the file, you can modify the file to add the name.

The makefile parameters specify the platform (required), compiler, and function. The makefile comment heading provides the description of these parameters.

Examples

The command

```
make lib64
```

builds a wrapper library for IA-64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler version 8.0 or higher (Compilers are chosen by default.).

The command

```
make lib64 compiler=gnu
```

builds a wrapper library for IA-64 architecture based applications using a GNU C compiler.

As a result of a makefile execution, the wrapper library will be created in the directory with Intel MKL libraries corresponding to the used platform. For example, `./lib/64` (on the Linux* OS and Mac OS* X) or `.\ia32\lib` (on the Windows* OS).

In the wrapper library names, the suffix corresponds to the used compiler and the underscore is preceded with letter "f" for Fortran and "c" for C.

For example,

`fftw3xf_intel.lib` (on the Windows OS) ; `libfftw3xf_intel.a` (on the Linux OS and Mac OS X);

`fftw3xc_intel.lib` (on the Windows OS); `libfftw3xc_intel.a` (on the Linux OS and Mac OS X);

`fftw3xc_ms.lib` (on the Windows OS); `libfftw3xc_gnu.a` (on the Linux OS and Mac OS X).

Application Assembling

To build C applications, use the adapted `fftw3.h` header file (see [Creating the Wrapper Library](#)).

To build Fortran applications, use the native `fftw3.h` header file.

Running Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw3xc` and `.\examples\fftw3xf` subdirectories in the Intel MKL directory. To build Fortran examples, one additional file `fftw3.f` is needed. This file is distributed with permission from FFTW and is available in the `.\include\fftw` subdirectory of the Intel MKL directory. The original file can also be found in FFTW 3.1 at <http://www.fftw.org/download.html>.

Example makefile parameters are the same as the wrapper library makefile parameters. Example makefiles normally invoke examples. However, if the appropriate wrapper library is not yet created, the makefile will first build it in the same way as the wrapper library makefile does and then proceed to examples.

If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples from the appropriate subdirectory will run. The subdirectory `._results` will be created, and the results will be stored there in the `<example_name>.res` files.

Bibliography

Glossary

A^H	Denotes the conjugate transpose of a general matrix A . See <i>also</i> conjugate matrix.
A^T	Denotes the transpose of a general matrix A . See <i>also</i> transpose.
band matrix	A general m -by- n matrix A such that $a_{ij} = 0$ for $ i - j > 1$, where $1 < 1 < \min(m, n)$. For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.
BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix A in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$) where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .
c	When found as the first letter of routine names, c indicates the usage of single-precision complex data type.
CBLAS	C interface to the BLAS. See BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable x . For univariate distribution the cumulative distribution function is the function of real argument x , which for every x takes a value equal to probability of the event $A: X \leq x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$, which, for every x , takes a value equal to probability of the event $A = (X_1 \leq x_1 \ \& \ X_2 \leq x_2, \ \& \ \dots, \ \& \ X_n \leq x_n)$.

Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A in the form $A = U^H U$ or $A = L L^H$, where L is a lower triangular matrix and U is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix A as follows: $\kappa(A) = \ A\ \ A^{-1}\ $.
conjugate matrix	The matrix A^H defined for a given general matrix A as follows: $(A^H)_{ij} = (a_{ji})^*$.
conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$.
d	When found as the first letter of routine names, d indicates the usage of double-precision real data type.
dot product	The number denoted $x \cdot y$ and defined for given vectors x and y as follows: $x \cdot y = \sum_i x_i y_i$. Here x_i and y_i stand for the i -th elements of x and y , respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $2.23 \times 10^{-308} < x < 1.79 \times 10^{308}$. For this data type, the machine precision ϵ is approximately 10^{-15} , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
eigenvalue	See eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors x and numbers λ (for a given square matrix A) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix A and the vectors x are called the eigenvectors of the matrix A .
eigenvector	See eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where v is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix Q in the QR factorization (the matrix Q is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, LU factorization, LQ factorization, QR factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.
full storage	A storage scheme allowing you to store matrices of any kind. A matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.

Hermitian matrix	A square matrix A that is equal to its conjugate matrix A^H . The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	See identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix A , $AI = A$ and $IA = A$.
i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel MKL	Abbreviation for Intel® Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix A as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices A .
LQ factorization	Representation of an m -by- n matrix A as $A = LQ$ or $A = (L \ 0)Q$. Here Q is an n -by- n orthogonal (unitary) matrix. For $m \leq n$, L is an m -by- m lower triangular matrix with real diagonal elements; for $m > n$,

$$L = \begin{bmatrix} L_1 \\ L_2 \end{bmatrix}$$

where L_1 is an n -by- n lower triangular matrix, and L_2 is a rectangular matrix.

LU factorization	Representation of a general m -by- n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).
machine precision	The number ϵ determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. See also double precision and single precision.
MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.

orthogonal matrix	A real square matrix A whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.
packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable x . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$. For univariate distribution the relation is

$$F(x) = \int_{-\infty}^x f(t) dt.$$

For multivariate distribution the relation is

$$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n.$$

positive-definitematrix	A square matrix A such that $Ax \cdot x > 0$ for any non-zero vector x . Here \cdot denotes the dot product.
pseudorandom number generator	A completely deterministic algorithm that imitates truly random sequences.
QR factorization	Representation of an m -by- n matrix A as $A = QR$, where Q is an m -by- m orthogonal (unitary) matrix, and R is n -by- n upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if $m < n$) matrix.
random stream	An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.
RNG	Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.

s	When found as the first letter of routine names, <i>s</i> indicates the usage of single-precision real data type.
ScaLAPACK	Stands for Scalable Linear Algebra PACKage.
Schur factorization	Representation of a square matrix A in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex A , triangular matrix) called the Schur form of A ; the matrix Z is orthogonal (for complex A , unitary). Columns of Z are called Schur vectors.
single precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $1.18 \times 10^{-38} < x < 3.40 \times 10^{38}$. For this data type, the machine precision (ϵ) is approximately 10^{-7} , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
singular matrix	A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H . <i>See also</i> SVD.
SMP	Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. <i>See</i> BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. <i>See</i> full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. <i>See also</i> Singular value decomposition section in Chapter 5.
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.
transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T , and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1 A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.

triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^HA = I$. All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. See Chapter 9 of this book.
VSL	Abbreviation for Vector Statistical Library. See Chapter 10 of this book.
z	When found as the first letter of routine names, z indicates the usage of double-precision complex data type.
