<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraints:</p> <p>If $n \leq 1$, <i>lwork</i> ≥ 1;</p> <p>If <i>jobz</i> = 'N' and $n > 1$, <i>lwork</i> $\geq 2n$;</p> <p>If <i>jobz</i> = 'V' and $n > 1$, <i>lwork</i> $\geq 2n^2 + 6n + 1$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the required sizes of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, its dimension $\max(1, lwork)$.</p>
<i>liwork</i>	INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *work* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as <i>B</i> .
<i>w</i> , <i>z</i>	REAL for <code>sspgv</code> DOUBLE PRECISION for <code>dspgv</code> . Arrays: <i>w</i> (*), DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order. <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If $jobz = 'V'$, then if $info = 0$, <i>z</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows: if $itype = 1$ or 2 , $Z^T * B * Z = I$; if $itype = 3$, $Z^T * \text{inv}(B) * Z = I$; If $jobz = 'N'$, then <i>z</i> is not referenced.
<i>work</i> (1)	On exit, if $info = 0$, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>iwork</i> (1)	On exit, if $info = 0$, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.
 If $info > 0$, `spptrf/dpptrf` and `sspevd/dspevd` returned an error code:
 If $info = i \leq n$, `sspevd/dspevd` failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;
 If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgvd` interface are the following:

<i>ap</i>	Holds the array A of size $(n * (n+1) / 2)$.
<i>bp</i>	Holds the array B of size $(n * (n+1) / 2)$.
<i>w</i>	Holds the vector with the number of elements n .
<i>z</i>	Holds the matrix Z of size (n, n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set $lwork = -1$ ($liwork = -1$).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work, iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hpgvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork,
lrwork, iwork, liwork, info)

call zhpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork,
lrwork, iwork, liwork, info)
```

Fortran 95:

```
call hpgvd(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `mk1_lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).</p>
<i>ap, bp, work</i>	<p>COMPLEX for chpgvd</p> <p>DOUBLE COMPLEX for zhpgvd.</p> <p>Arrays:</p> <p><i>ap</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>bp</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>B</i>, as specified by <i>uplo</i>.</p> <p>The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraints:</p> <p>If $n \leq 1$, $lwork \geq 1$;</p> <p>If <i>jobz</i> = 'N' and $n > 1$, $lwork \geq n$;</p> <p>If <i>jobz</i> = 'V' and $n > 1$, $lwork \geq 2n$.</p>

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork

REAL for *chpgvd*

DOUBLE PRECISION for *zhpgvd*.

Workspace array, its dimension $\max(1, lrwork)$.

lrwork

INTEGER.

The dimension of the array *rwork*.

Constraints:

If $n \leq 1$, $lrwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;

If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as B .
<i>w</i>	REAL for <code>chpgvd</code> DOUBLE PRECISION for <code>zhpgvd</code> . Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	COMPLEX for <code>chpgvd</code> DOUBLE COMPLEX for <code>zhpgvd</code> . Array <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$; If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0, <code>cpptrf/zpptrf</code> and <code>chpevd/zhpevd</code> returned an error code: If <i>info</i> = <i>i</i> ≤ <i>n</i> , <code>chpevd/zhpevd</code> failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpgvd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array B of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of `lwork` (`liwork` or `lrwork`) for the first run or set `lwork = -1` (`liwork = -1`, `lrwork = -1`).

If you choose the first option and set any of admissible `lwork` (`liwork` or `lrwork`) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`) on exit. Use this value (`work(1)`, `iwork(1)`, `rwork(1)`) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call sspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, iwork, ifail, info)

call dspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, iwork, ifail, info)
```

Fortran 95:

```
call spgvx(ap, bp, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'.

If *jobz* = 'N', then compute eigenvalues only.
 If *jobz* = 'V', then compute eigenvalues and eigenvectors.

range CHARACTER*1. Must be 'A' or 'V' or 'I'.
 If *range* = 'A', the routine computes all eigenvalues.
 If *range* = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:
 $vl < \lambda(i) \leq vu$.
 If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', arrays *ap* and *bp* store the upper triangles of *A* and *B*;
 If *uplo* = 'L', arrays *ap* and *bp* store the lower triangles of *A* and *B*.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ap, bp, work REAL for sspgvx
 DOUBLE PRECISION for dspgvx.
 Arrays:
ap(*) contains the packed upper or lower triangle of the symmetric matrix *A*, as specified by *uplo*.
 The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.
bp(*) contains the packed upper or lower triangle of the symmetric matrix *B*, as specified by *uplo*.
 The dimension of *bp* must be at least $\max(1, n*(n+1)/2)$.
work(*) is a workspace array, DIMENSION at least $\max(1, 8n)$.

vl, vu REAL for sspgvx
 DOUBLE PRECISION for dspgvx.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$

if $n = 0$.
 If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol REAL for sspgvx
 DOUBLE PRECISION for dspgvx.
 The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz INTEGER. The leading dimension of the output array z .
 Constraints:
 $ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$.

iwork INTEGER.
 Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap On exit, the contents of ap are overwritten.

bp On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as B .

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$,
 $m = iu - il + 1$.

w, z REAL for sspgvx
 DOUBLE PRECISION for dspgvx.
 Arrays:
 $w(*)$, DIMENSION at least $\max(1, n)$.
 If $info = 0$, contains the eigenvalues in ascending order.
 $z(ldz, *)$.
 The second dimension of z must be at least $\max(1, n)$.
 If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.
 The eigenvectors are normalized as follows:
 if $itype = 1$ or 2 , $z^T * B * z = I$;
 if $itype = 3$, $z^T * \text{inv}(B) * z = I$;
 If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, *spptrf*/*dpptrf* and *sspevx*/*dspevx* returned an error code:

If $info = i \leq n$, *sspevx*/*dspevx* failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spgvx* interface are the following:

<i>ap</i>	Holds the array A of size $(n * (n+1) / 2)$.
<i>bp</i>	Holds the array B of size $(n * (n+1) / 2)$.
<i>w</i>	Holds the vector with the number of elements n .

<i>z</i>	Holds the matrix <i>z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot ||T||_1$ is used instead, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, set *abstol* to $2 * ?lamch('S')$.

?hpgvx

Computes selected eigenvalues and, optionally, eigenvectors of a generalized Hermitian definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call chpgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, rwork, iwork, ifail, info)
```

```
call zhpgrvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hpgvx(ap, bp, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `mk1_lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only.

<i>range</i>	<p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p> <p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:</p> $vl < \lambda(i) \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i>.</p>
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ap, bp, work</i>	<p>COMPLEX for chpgvx</p> <p>DOUBLE COMPLEX for zhpgvx.</p> <p>Arrays:</p> <p><i>ap</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>. The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>bp</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>B</i>, as specified by <i>uplo</i>. The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>work</i>(*) is a workspace array, DIMENSION at least $\max(1, 2n)$.</p>
<i>vl, vu</i>	<p>REAL for chpgvx</p> <p>DOUBLE PRECISION for zhpgvx.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p>

	If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for <code>chpgvx</code> DOUBLE PRECISION for <code>zhpgvx</code> . The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>rwork</i>	REAL for <code>chpgvx</code> DOUBLE PRECISION for <code>zhpgvx</code> . Workspace array, DIMENSION at least $\max(1, 7n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as <i>B</i> .
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.
<i>w</i>	REAL for <code>chpgvx</code> DOUBLE PRECISION for <code>zhpgvx</code> . Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	COMPLEX for <code>chpgvx</code> DOUBLE COMPLEX for <code>zhpgvx</code> . Array <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$;

if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, `cpptrf/zpptrf` and `chpevx/zhpevx` returned an error code:

If $info = i \leq n$, `chpevx/zhpevx` failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array $ifail$;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpgvx` interface are the following:

ap Holds the array A of size $(n * (n+1) / 2)$.

bp Holds the array B of size $(n * (n+1) / 2)$.

<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot \|T\|_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 \cdot \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 \cdot \text{lamch}('S')$.

?sbgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call ssbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
call dsbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
```

Fortran 95:

```
call sbgv(ab, bb, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).

<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> (<i>kb</i> ≥ 0).
<i>ab, bb, work</i>	REAL for ssbgv DOUBLE PRECISION for dsbgv Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $\max(1, 3n)$
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least <i>ka</i> +1.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least <i>kb</i> +1.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> ≥ 1 . If <i>jobz</i> = 'V', <i>ldz</i> $\geq \max(1, n)$.

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^T * S$, as returned by spbstf/dpbstf .
<i>w, z</i>	REAL for ssbgv DOUBLE PRECISION for dsbgv Arrays: <i>w</i> (*), DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order. <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, *z* contains the matrix *Z* of eigenvectors, with the *i*-th column of *z* holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T * B * Z = I$.

If *jobz* = 'N', then *z* is not referenced.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th argument had an illegal value.

If *info* > 0, and

if $i \leq n$, the algorithm failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then `spbstf/dpbstf` returned *info* = *i* and *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgv` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(ka+1, n)$.
<i>bb</i>	Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

?hbgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call chbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
```

```
call zhbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hbgv(ab, bb, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are Hermitian and banded matrices, and matrix B is also positive definite.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in A

	$(ka \geq 0)$.
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$).
<i>ab, bb, work</i>	COMPLEX for <i>chbgv</i> DOUBLE COMPLEX for <i>zhbgv</i> Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. <i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>rwork</i>	REAL for <i>chbgv</i> DOUBLE PRECISION for <i>zhbgv</i> . Workspace array, DIMENSION at least $\max(1, 3n)$.

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^H * S$, as returned by cpbstf / zpbstf .
<i>w</i>	REAL for <i>chbgv</i> DOUBLE PRECISION for <i>zhbgv</i> . Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

z COMPLEX for chbgv
 DOUBLE COMPLEX for zhbqv
 Array $z(ldz,*)$.
 The second dimension of z must be at least $\max(1, n)$.
 If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z
 of eigenvectors, with the i -th column of z holding the
 eigenvector associated with $w(i)$. The eigenvectors are
 normalized so that $Z^H * B * Z = I$.
 If $jobz = 'N'$, then z is not referenced.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th argument had an illegal value.
 If $info > 0$, and
 if $i \leq n$, the algorithm failed to converge, and i off-diagonal
 elements of an intermediate tridiagonal did not converge to
 zero;
 if $info = n + i$, for $1 \leq i \leq n$, then [cpbstf/zpbstf](#)
 returned $info = i$ and B is not positive-definite. The
 factorization of B could not be completed and no eigenvalues
 or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbqv` interface are the following:

ab	Holds the array A of size $(ka+1, n)$.
bb	Holds the array B of size $(kb+1, n)$.
w	Holds the vector with the number of elements n .
z	Holds the matrix Z of size (n, n) .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

?sbgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call ssbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
            iwork, liwork, info)

call dsbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
            iwork, liwork, info)
```

Fortran 95:

```
call sbgvd(ab, bb, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x = \lambda*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<code>jobz</code>	CHARACTER*1. Must be 'N' or 'V'. If <code>jobz</code> = 'N', then compute eigenvalues only. If <code>jobz</code> = 'V', then compute eigenvalues and eigenvectors.
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo</code> = 'U', arrays <code>ab</code> and <code>bb</code> store the upper triangles of A and B ; If <code>uplo</code> = 'L', arrays <code>ab</code> and <code>bb</code> store the lower triangles of A and B .

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ka INTEGER. The number of super- or sub-diagonals in *A* ($ka \geq 0$).

kb INTEGER. The number of super- or sub-diagonals in *B* ($kb \geq 0$).

ab, bb, work REAL for *ssbgvd*
 DOUBLE PRECISION for *dsbgvd*
 Arrays:
ab(*ldab*,*) is an array containing either upper or lower triangular part of the symmetric matrix *A* (as specified by *uplo*) in band storage format.
 The second dimension of the array *ab* must be at least $\max(1, n)$.
bb(*ldbb*,*) is an array containing either upper or lower triangular part of the symmetric matrix *B* (as specified by *uplo*) in band storage format.
 The second dimension of the array *bb* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

ldab INTEGER. The first dimension of the array *ab*; must be at least $ka+1$.

ldbb INTEGER. The first dimension of the array *bb*; must be at least $kb+1$.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*.
 Constraints:
 If $n \leq 1$, $lwork \geq 1$;
 If *jobz* = 'N' and $n > 1$, $lwork \geq 3n$;
 If *jobz* = 'V' and $n > 1$, $lwork \geq 2n^2+5n+1$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the

work and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.
Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*.
Constraints:
If $n \leq 1$, $liwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;
If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.
If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

ab On exit, the contents of *ab* are overwritten.

bb On exit, contains the factor *s* from the split Cholesky factorization $B = S^T * S$, as returned by [spbstf/dpbstf](#).

w, z REAL for ssbgvd
DOUBLE PRECISION for dsbgvd
Arrays:
w(*), DIMENSION at least $\max(1, n)$.
If *info* = 0, contains the eigenvalues in ascending order.
z(ldz,*).
The second dimension of *z* must be at least $\max(1, n)$.
If $jobz = 'V'$, then if *info* = 0, *z* contains the matrix *Z* of eigenvectors, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*). The eigenvectors are normalized so that $Z^T * B * Z = I$.
If $jobz = 'N'$, then *z* is not referenced.

<code>work(1)</code>	On exit, if <code>info = 0</code> , then <code>work(1)</code> returns the required minimal size of <code>lwork</code> .
<code>iwork(1)</code>	On exit, if <code>info = 0</code> , then <code>iwork(1)</code> returns the required minimal size of <code>liwork</code> .
<code>info</code>	<p>INTEGER.</p> <p>If <code>info = 0</code>, the execution is successful.</p> <p>If <code>info = -i</code>, the <i>i</i>-th argument had an illegal value.</p> <p>If <code>info > 0</code>, and</p> <p>if $i \leq n$, the algorithm failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero;</p> <p>if <code>info = n + i</code>, for $1 \leq i \leq n$, then <code>spbstf/dpbstf</code> returned <code>info = i</code> and <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgvd` interface are the following:

<code>ab</code>	Holds the array <i>A</i> of size $(ka+1, n)$.
<code>bb</code>	Holds the array <i>B</i> of size $(kb+1, n)$.
<code>w</code>	Holds the vector with the number of elements <i>n</i> .
<code>z</code>	Holds the matrix <i>Z</i> of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	<p>Restored based on the presence of the argument <i>z</i> as follows:</p> <p><code>jobz = 'V'</code>, if <i>z</i> is present,</p> <p><code>jobz = 'N'</code>, if <i>z</i> is omitted.</p>

Application Notes

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork = -1` (`liwork = -1`).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *work* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hbgvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
rwork, lrwork, iwork, liwork, info)

call zhbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call hbgvd(ab, bb, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x = \lambda*B*x$. Here *A* and *B* are assumed to be Hermitian and banded, and *B* is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i>.</p>
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	<p>INTEGER. The number of super- or sub-diagonals in <i>A</i></p> <p>($ka \geq 0$).</p>
<i>kb</i>	<p>INTEGER. The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$).</p>
<i>ab, bb, work</i>	<p>COMPLEX for <i>chbgvd</i></p> <p>DOUBLE COMPLEX for <i>zhbgvd</i></p> <p>Arrays:</p> <p><i>ab</i>(<i>ldab</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of the array <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>bb</i>(<i>ldbb</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of the array <i>bb</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>ldab</i>	<p>INTEGER. The first dimension of the array <i>ab</i>; must be at least $ka+1$.</p>
<i>ldbb</i>	<p>INTEGER. The first dimension of the array <i>bb</i>; must be at least $kb+1$.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.</p>

<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraints:</p> <p>If $n \leq 1$, $lwork \geq 1$;</p> <p>If $jobz = 'N'$ and $n > 1$, $lwork \geq n$;</p> <p>If $jobz = 'V'$ and $n > 1$, $lwork \geq 2n^2$.</p> <p>If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>lrwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.</p>
<i>rwork</i>	<p>REAL for <i>chbgvd</i></p> <p>DOUBLE PRECISION for <i>zhbgvd</i>.</p> <p>Workspace array, DIMENSION $\max(1, lrwork)$.</p>
<i>lrwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>rwork</i>.</p> <p>Constraints:</p> <p>If $n \leq 1$, $lrwork \geq 1$;</p> <p>If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;</p> <p>If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.</p> <p>If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>lrwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION $\max(1, liwork)$.</p>
<i>liwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>iwork</i>.</p> <p>Constraints:</p> <p>If $n \leq 1$, $lwork \geq 1$;</p> <p>If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;</p>

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

ab	On exit, the contents of ab are overwritten.
bb	On exit, contains the factor s from the split Cholesky factorization $B = S^H * S$, as returned by cpbstf/zpbstf .
w	REAL for chbgvd DOUBLE PRECISION for zhbgvd . Array, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order.
z	COMPLEX for chbgvd DOUBLE COMPLEX for zhbgvd Array $z(ldz,*)$. The second dimension of z must be at least $\max(1, n)$. If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors , with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^H * B * Z = I$. If $jobz = 'N'$, then z is not referenced.
$work(1)$	On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.
$rwork(1)$	On exit, if $info = 0$, then $rwork(1)$ returns the required minimal size of $lrwork$.
$iwork(1)$	On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th argument had an illegal value. If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;
 if $info = n + i$, for $1 \leq i \leq n$, then `cpbstf/zpbstf` returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbgvd` interface are the following:

<i>ab</i>	Holds the array A of size $(ka+1, n)$.
<i>bb</i>	Holds the array B of size $(kb+1, n)$.
<i>w</i>	Holds the vector with the number of elements n .
<i>z</i>	Holds the matrix Z of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value ($work(1)$, $iwork(1)$, $rwork(1)$) for subsequent runs.

If you set $lwork = -1$ ($liwork = -1$, $lrwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call ssbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, iwork, ifail, info)

call dsbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, iwork, ifail, info)
```

Fortran 95:

```
call sbgvx(ab, bb, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q]
[,abstol] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<code>jobz</code>	CHARACTER*1. Must be 'N' or 'V'. If <code>jobz</code> = 'N', then compute eigenvalues only. If <code>jobz</code> = 'V', then compute eigenvalues and eigenvectors.
<code>range</code>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <code>range</code> = 'A', the routine computes all eigenvalues.

	<p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:</p> $vl < \lambda(i) \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues in range <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i>.</p>
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$).
<i>ab, bb, work</i>	<p>REAL for ssbgvx DOUBLE PRECISION for dsbgvx</p> <p>Arrays:</p> <p><i>ab</i>(<i>ldab</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of the array <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>bb</i>(<i>ldbb</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of the array <i>bb</i> must be at least $\max(1, n)$.</p> <p><i>work</i>(*) is a workspace array, DIMENSION (7*n).</p>
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least <i>ka</i> +1.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least <i>kb</i> +1.
<i>vl, vu</i>	<p>REAL for ssbgvx DOUBLE PRECISION for dsbgvx.</p>

	<p>If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If $range = 'A'$ or $'I'$, vl and vu are not referenced.</p>
il, iu	<p>INTEGER.</p> <p>If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If $range = 'A'$ or $'V'$, il and iu are not referenced.</p>
$abstol$	<p>REAL for <code>ssbgvx</code> DOUBLE PRECISION for <code>dsbgvx</code>.</p> <p>The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.</p>
ldz	<p>INTEGER. The leading dimension of the output array z; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.</p>
ldq	<p>INTEGER. The leading dimension of the output array q; $ldq < 1$.</p> <p>If $jobz = 'V'$, $ldq < \max(1, n)$.</p>
$iwork$	<p>INTEGER.</p> <p>Workspace array, DIMENSION $(5*n)$.</p>

Output Parameters

ab	On exit, the contents of ab are overwritten.
bb	On exit, contains the factor S from the split Cholesky factorization $B = S^T * S$, as returned by spbstf / dpbstf .
m	<p>INTEGER. The total number of eigenvalues found,</p> <p>$0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.</p>
w, z, q	<p>REAL for <code>ssbgvx</code> DOUBLE PRECISION for <code>dsbgvx</code></p> <p>Arrays:</p> <p>$w(*)$, DIMENSION at least $\max(1, n)$.</p> <p>If $info = 0$, contains the eigenvalues in ascending order.</p> <p>$z(ldz,*)$.</p>

The second dimension of z must be at least $\max(1, n)$.
 If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T B Z = I$.

If $jobz = 'N'$, then z is not referenced.

$q(ldq,*)$.

The second dimension of q must be at least $\max(1, n)$.

If $jobz = 'V'$, then q contains the n -by- n matrix used in the reduction of $A*x = \lambda*B*x$ to standard form, that is, $C*x = \lambda*x$ and consequently C to tridiagonal form.

If $jobz = 'N'$, then q is not referenced.

ifail

INTEGER.

Array, DIMENSION (m).

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then [spbstf/dpbstf](#) returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgvx` interface are the following:

ab

Holds the array A of size $(ka+1, n)$.

<i>bb</i>	Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?lamch('S')$.

?hbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call chbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, rwork, iwork, ifail, info)
```

```
call zhbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hbgvx(ab, bb, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q]
[,abstol] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `mk1_lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$.

If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', arrays *ab* and *bb* store the upper triangles of *A* and *B*;
 If *uplo* = 'L', arrays *ab* and *bb* store the lower triangles of *A* and *B*.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ka INTEGER. The number of super- or sub-diagonals in *A* ($ka \geq 0$).

kb INTEGER. The number of super- or sub-diagonals in *B* ($kb \geq 0$).

ab, *bb*, *work* COMPLEX for *chbgvx*
 DOUBLE COMPLEX for *zhbgvx*
Arrays:
ab (*ldab*,*) is an array containing either upper or lower triangular part of the Hermitian matrix *A* (as specified by *uplo*) in band storage format.
 The second dimension of the array *ab* must be at least $\max(1, n)$.
bb (*ldbb*,*) is an array containing either upper or lower triangular part of the Hermitian matrix *B* (as specified by *uplo*) in band storage format.
 The second dimension of the array *bb* must be at least $\max(1, n)$.
work (*) is a workspace array, DIMENSION at least $\max(1, n)$.

ldab INTEGER. The first dimension of the array *ab*; must be at least $ka+1$.

ldbb INTEGER. The first dimension of the array *bb*; must be at least $kb+1$.

vl, *vu* REAL for *chbgvx*
 DOUBLE PRECISION for *zhbgvx*.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

	<p>Constraint: $vl < vu$.</p> <p>If $range = 'A'$ or $'I'$, vl and vu are not referenced.</p>
il, iu	<p>INTEGER.</p> <p>If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If $range = 'A'$ or $'V'$, il and iu are not referenced.</p>
$abstol$	<p>REAL for chbgvx DOUBLE PRECISION for zhbgbvx.</p> <p>The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.</p>
ldz	<p>INTEGER. The leading dimension of the output array z; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.</p>
ldq	<p>INTEGER. The leading dimension of the output array q; $ldq \geq 1$. If $jobz = 'V'$, $ldq \geq \max(1, n)$.</p>
$rwork$	<p>REAL for chbgvx DOUBLE PRECISION for zhbgbvx.</p> <p>Workspace array, DIMENSION at least $\max(1, 7n)$.</p>
$iwork$	<p>INTEGER.</p> <p>Workspace array, DIMENSION at least $\max(1, 5n)$.</p>

Output Parameters

ab	On exit, the contents of ab are overwritten.
bb	On exit, contains the factor s from the split Cholesky factorization $B = S^H * S$, as returned by cpbstf/zpbstf .
m	<p>INTEGER. The total number of eigenvalues found,</p> <p>$0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.</p>
w	<p>REAL for chbgvx DOUBLE PRECISION for zhbgbvx.</p> <p>Array $w(*)$, DIMENSION at least $\max(1, n)$.</p> <p>If $info = 0$, contains the eigenvalues in ascending order.</p>
z, q	COMPLEX for chbgvx

DOUBLE COMPLEX for zhbgvx

Arrays:

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^{H*}B*Z = I$.

If $jobz = 'N'$, then z is not referenced.

$q(ldq,*)$.

The second dimension of q must be at least $\max(1, n)$.

If $jobz = 'V'$, then q contains the n -by- n matrix used in the reduction of $Ax = \lambda Bx$ to standard form, that is, $Cx = \lambda x$ and consequently C to tridiagonal form.

If $jobz = 'N'$, then q is not referenced.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then [cpbstf/zpbstf](#) returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbgvx` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(ka+1, n)$.
<i>bb</i>	Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If `abstol` is less than or equal to zero, then $\varepsilon^* ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold `2*?lamch('S')`, not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, try setting `abstol` to `2*?lamch('S')`.

Generalized Nonsymmetric Eigenproblems

This section describes LAPACK driver routines used for solving generalized nonsymmetric eigenproblems. See also computational routines [computational routines](#) that can be called to solve these problems. [Table 4-14](#) lists all such driver routines for FORTRAN 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-14 Driver Routines for Solving Generalized Nonsymmetric Eigenproblems

Routine Name	Operation performed
<code>?gges</code>	Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.
<code>?ggesx</code>	Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.
<code>?ggeev</code>	Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.
<code>?ggeevx</code>	Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

?gges

Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.

Syntax

FORTRAN 77:

```
call sgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alphas,
alpha, beta, vsl, ldvsl, vsr, ldvsr, work, lwork, bwork, info)

call dgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alphas,
alpha, beta, vsl, ldvsl, vsr, ldvsr, work, lwork, bwork, info)

call cgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alpha, beta,
vsl, ldvsl, vsr, ldvsr, work, lwork, rwork, bwork, info)

call zgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alpha, beta,
vsl, ldvsl, vsr, ldvsr, work, lwork, rwork, bwork, info)
```

Fortran 95:

```
call gges(a, b, alphas, alpha, beta [,vsl] [,vsr] [,select] [,sdim] [,info])
call gges(a, b, alpha, beta [, vsl] [,vsr] [,select] [,sdim] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A, B) , the generalized eigenvalues, the generalized real/complex Schur form (S, T) , optionally, the left and/or right matrices of Schur vectors (vsl and vsr). This gives the generalized Schur factorization

$$(A, B) = (vsl * S * vsr^H, vsl * T * vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T . The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver [?ggeev](#) instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A, B) is a scalar w or a ratio $\alpha / \beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$ or for both being zero. A pair of matrices (S, T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S, T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

Input Parameters

<i>jobvsl</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvsl</i> = 'N', then the left Schur vectors are not computed.</p> <p>If <i>jobvsl</i> = 'V', then the left Schur vectors are computed.</p>
<i>jobvsr</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed.</p> <p>If <i>jobvsr</i> = 'V', then the right Schur vectors are computed.</p>
<i>sort</i>	<p>CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.</p> <p>If <i>sort</i> = 'N', then eigenvalues are not ordered.</p> <p>If <i>sort</i> = 'S', eigenvalues are ordered (see <i>selctg</i>).</p>
<i>selctg</i>	<p>LOGICAL FUNCTION of three REAL arguments for real flavors.</p> <p>LOGICAL FUNCTION of two COMPLEX arguments for complex flavors.</p> <p><i>selctg</i> must be declared EXTERNAL in the calling subroutine.</p>

If `sort = 'S'`, `selctg` is used to select eigenvalues to sort to the top left of the Schur form.

If `sort = 'N'`, `selctg` is not referenced.

For real flavors:

An eigenvalue $(\text{alphan}(j) + \text{alphai}(j))/\text{betan}(j)$ is selected if `selctg(alphan(j), alphai(j), betan(j))` is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy `selctg(alphan(j), alphai(j), betan(j)) = .TRUE.` after ordering. In this case `info` is set to `n+2`.

For complex flavors:

An eigenvalue $\text{alpha}(j) / \text{betan}(j)$ is selected if `selctg(alpha(j), betan(j))` is true.

Note that a selected complex eigenvalue may no longer satisfy `selctg(alpha(j), betan(j)) = .TRUE.` after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case `info` is set to `n+2` (see `info` below).

`n` INTEGER. The order of the matrices `A`, `B`, `vsl`, and `vsr` ($n \geq 0$).

`a`, `b`, `work` REAL for `sgges`
DOUBLE PRECISION for `dgges`
COMPLEX for `cgges`
DOUBLE COMPLEX for `zgges`.

Arrays:

`a(lda,*)` is an array containing the n -by- n matrix `A` (first of the pair of matrices).

The second dimension of `a` must be at least $\max(1, n)$.

`b(ldb,*)` is an array containing the n -by- n matrix `B` (second of the pair of matrices).

The second dimension of `b` must be at least $\max(1, n)$.

`work` is a workspace array, its dimension $\max(1, lwork)$.

`lda` INTEGER. The first dimension of the array `a`. Must be at least $\max(1, n)$.

<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> . Must be at least $\max(1, n)$.
<i>ldvsl, ldvsr</i>	INTEGER. The first dimensions of the output matrices <i>vsl</i> and <i>vsr</i> , respectively. Constraints: $ldvsl \geq 1$. If <i>jobvsl</i> = 'V', $ldvsl \geq \max(1, n)$. $ldvsr \geq 1$. If <i>jobvsr</i> = 'V', $ldvsr \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork \geq \max(1, 8n+16)$ for real flavors; $lwork \geq \max(1, 2n)$ for complex flavors. For good performance, <i>lwork</i> must generally be larger. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla .
<i>rwork</i>	REAL for <i>cgges</i> DOUBLE PRECISION for <i>zgges</i> Workspace array, DIMENSION at least $\max(1, 8n)$. This array is used in complex flavors only.
<i>bwork</i>	LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$. Not referenced if <i>sort</i> = 'N'.

Output Parameters

<i>a</i>	On exit, this array has been overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, this array has been overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	INTEGER. If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> is equal to the number of eigenvalues (after sorting) for which <i>selctg</i> is true. Note that for real flavors complex conjugate pairs for which <i>selctg</i> is true for either eigenvalue count as 2.
<i>alphar, alphas</i>	REAL for <i>sgges</i> ;

	DOUBLE PRECISION for dgges. Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> .
<i>alpha</i>	COMPLEX for cgges; DOUBLE COMPLEX for zgges. Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	REAL for sgges DOUBLE PRECISION for dgges COMPLEX for cgges DOUBLE COMPLEX for zgges. Array, DIMENSION at least $\max(1, n)$. <i>For real flavors:</i> On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues. $\text{alphar}(j) + \text{alphai}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $\text{alphai}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{alphai}(j+1)$ negative. <i>For complex flavors:</i> On exit, $\text{alpha}(j)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues. $\text{alpha}(j)$, $j=1, \dots, n$, and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) output by cgges/zgges. The $\text{beta}(j)$ will be non-negative real. See also <i>Application Notes</i> below.
<i>vsl, vsr</i>	REAL for sgges DOUBLE PRECISION for dgges COMPLEX for cgges DOUBLE COMPLEX for zgges. Arrays: $\text{vsl}(\text{ldvsl}, *)$, the second dimension of <i>vsl</i> must be at least $\max(1, n)$.

If `jobvsl = 'V'`, this array will contain the left Schur vectors.
 If `jobvsl = 'N'`, `vsl` is not referenced.
`vsr(ldvsr,*)`, the second dimension of `vsr` must be at least $\max(1, n)$.
 If `jobvsr = 'V'`, this array will contain the right Schur vectors.
 If `jobvsr = 'N'`, `vsr` is not referenced.

`work(1)` On exit, if `info = 0`, then `work(1)` returns the required minimal size of `lwork`.

`info` INTEGER.
 If `info = 0`, the execution is successful.
 If `info = -i`, the *i*th parameter had an illegal value.
 If `info = i`, and
 $i \leq n$:
 the QZ iteration failed. (*A*, *B*) is not in Schur form, but `alphar(j)`, `alpha(i)` (for real flavors), or `alpha(j)` (for complex flavors), and `beta(j)`, $j = \text{info} + 1, \dots, n$ should be correct.
 $i > n$: errors that usually indicate LAPACK problems:
 $i = n + 1$: other than QZ iteration failed in `?hgeqz`;
 $i = n + 2$: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy `selctg = .TRUE..`
 This could also be caused due to scaling;
 $i = n + 3$: reordering failed in `?tgsen`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gges` interface are the following:

<code>a</code>	Holds the matrix <i>A</i> of size (n, n) .
<code>b</code>	Holds the matrix <i>B</i> of size (n, n) .
<code>alphar</code>	Holds the vector of length <i>n</i> . Used in real flavors only.
<code>alpha(i)</code>	Holds the vector of length <i>n</i> . Used in real flavors only.

<i>alpha</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>vsl</i>	Holds the matrix <i>VSL</i> of size (<i>n</i> , <i>n</i>).
<i>vsr</i>	Holds the matrix <i>VSR</i> of size (<i>n</i> , <i>n</i>).
<i>jobvsl</i>	Restored based on the presence of the argument <i>vsl</i> as follows: <i>jobvsl</i> = 'V', if <i>vsl</i> is present, <i>jobvsl</i> = 'N', if <i>vsl</i> is omitted.
<i>jobvsr</i>	Restored based on the presence of the argument <i>vsr</i> as follows: <i>jobvsr</i> = 'V', if <i>vsr</i> is present, <i>jobvsr</i> = 'N', if <i>vsr</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>sort</i> = 'S', if <i>select</i> is present, <i>sort</i> = 'N', if <i>select</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar*(*j*)/*beta*(*j*) and *alphai*(*j*)/*beta*(*j*) may easily over- or underflow, and *beta*(*j*) may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* will be always less than and usually comparable with norm(*A*) in magnitude, and *beta* always less than and usually comparable with norm(*B*).

?ggesx

Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.

Syntax

FORTRAN 77:

```
call sggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
  alphas, alphas, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork,
  iwork, liwork, bwork, info)
```

```
call dggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
  alphas, alphas, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork,
  iwork, liwork, bwork, info)
```

```
call cggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
  alpha, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, rwork,
  iwork, liwork, bwork, info)
```

```
call zggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
  alpha, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, rwork,
  iwork, liwork, bwork, info)
```

Fortran 95:

```
call ggesx(a, b, alphas, alphas, beta [,vsl] [,vsr] [,select] [,sdim] [,rconde]
  [, rcondv] [,info])
```

```
call ggesx(a, b, alpha, beta [, vsl] [,vsr] [,select] [,sdim] [,rconde]
  [,rcondv] [, info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, the generalized real/complex Schur form (S,T) , optionally, the left and/or right matrices of Schur vectors (vsl and vsr). This gives the generalized Schur factorization

$$(A,B) = (vsl * S * vsr^H, vsl * T * vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T ; computes a reciprocal condition number for the average of the selected eigenvalues ($rconde$); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues ($rcondv$). The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $alpha / beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta=0$ or for both being zero. A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

Input Parameters

$jobvsl$	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If $jobvsl = 'N'$, then the left Schur vectors are not computed.</p> <p>If $jobvsl = 'V'$, then the left Schur vectors are computed.</p>
$jobvsr$	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If $jobvsr = 'N'$, then the right Schur vectors are not computed.</p> <p>If $jobvsr = 'V'$, then the right Schur vectors are computed.</p>

<i>sort</i>	<p>CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.</p> <p>If <i>sort</i> = 'N', then eigenvalues are not ordered.</p> <p>If <i>sort</i> = 'S', eigenvalues are ordered (see <i>selctg</i>).</p>
<i>selctg</i>	<p>LOGICAL FUNCTION of three REAL arguments for real flavors.</p> <p>LOGICAL FUNCTION of two COMPLEX arguments for complex flavors.</p> <p><i>selctg</i> must be declared EXTERNAL in the calling subroutine.</p> <p>If <i>sort</i> = 'S', <i>selctg</i> is used to select eigenvalues to sort to the top left of the Schur form.</p> <p>If <i>sort</i> = 'N', <i>selctg</i> is not referenced.</p> <p>For real flavors:</p> <p>An eigenvalue $(\text{alphar}(j) + \text{alphai}(j))/\text{beta}(j)$ is selected if <i>selctg</i>(<i>alphar</i>(<i>j</i>), <i>alphai</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy <i>selctg</i>(<i>alphar</i>(<i>j</i>), <i>alphai</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) = .TRUE. after ordering. In this case <i>info</i> is set to <i>n</i>+2.</p> <p>For complex flavors:</p> <p>An eigenvalue $\text{alpha}(j) / \text{beta}(j)$ is selected if <i>selctg</i>(<i>alpha</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) is true.</p> <p>Note that a selected complex eigenvalue may no longer satisfy <i>selctg</i>(<i>alpha</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> is set to <i>n</i>+2 (see <i>info</i> below).</p>
<i>sense</i>	<p>CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for average of selected eigenvalues only;</p> <p>If <i>sense</i> = 'V', computed for selected deflating subspaces only;</p> <p>If <i>sense</i> = 'B', computed for both.</p>

If *sense* is 'E', 'V', or 'B', then *sort* must equal 'S'.

n INTEGER. The order of the matrices *A*, *B*, *vsl*, and *vsr* ($n \geq 0$).

a, *b*, *work* REAL for sggesx
DOUBLE PRECISION for dggesx
COMPLEX for cggesx
DOUBLE COMPLEX for zggesx.

Arrays:
a(lda,)* is an array containing the *n*-by-*n* matrix *A* (first of the pair of matrices).
 The second dimension of *a* must be at least $\max(1, n)$.
b(ldb,)* is an array containing the *n*-by-*n* matrix *B* (second of the pair of matrices).
 The second dimension of *b* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array *a*.
Must be at least $\max(1, n)$.

ldb INTEGER. The first dimension of the array *b*.
Must be at least $\max(1, n)$.

ldvsl, *ldvsr* INTEGER. The first dimensions of the output matrices *vsl* and *vsr*, respectively. Constraints:
 $ldvsl \geq 1$. If *jobvsl* = 'V', $ldvsl \geq \max(1, n)$.
 $ldvsr \geq 1$. If *jobvsr* = 'V', $ldvsr \geq \max(1, n)$.

lwork INTEGER.
The dimension of the array *work*.
For real flavors:
 If $n=0$ then $lwork \geq 1$.
 If $n>0$ and *sense* = 'N', then $lwork \geq \max(8*n, 6*n+16)$.
 If $n>0$ and *sense* = 'E', 'V', or 'B', then $lwork \geq \max(8*n, 6*n+16, 2*sdim*(n-sdim))$;
For complex flavors:
 If $n=0$ then $lwork \geq 1$.
 If $n>0$ and *sense* = 'N', then $lwork \geq \max(1, 2*n)$;

If $n > 0$ and $sense = 'E', 'V',$ or $'B'$, then $lwork \geq \max(1, 2*n, 2*sdim*(n-sdim))$.

Note that $2*sdim*(n-sdim) \leq n*n/2$.

An error is only returned if $lwork < \max(8*n, 6*n+16)$ for real flavors, and $lwork < \max(1, 2*n)$ for complex flavors, but if $sense = 'E', 'V',$ or $'B'$, this may not be large enough.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by xerbla.

rwork

REAL for cggexx

DOUBLE PRECISION for zggexx

Workspace array, DIMENSION at least $\max(1, 8n)$.

This array is used in complex flavors only.

iwork

INTEGER.

Workspace array, DIMENSION $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

If $sense = 'N'$, or $n = 0$, then $liwork \geq 1$,

otherwise $liwork \geq (n+6)$ for real flavors, and $liwork \geq (n+2)$ for complex flavors.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by xerbla.

bwork

LOGICAL.

Workspace array, DIMENSION at least $\max(1, n)$.

Not referenced if $sort = 'N'$.

Output Parameters

<i>a</i>	On exit, this array has been overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, this array has been overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	INTEGER. If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> is equal to the number of eigenvalues (after sorting) for which <i>selctg</i> is true. Note that for real flavors complex conjugate pairs for which <i>selctg</i> is true for either eigenvalue count as 2.
<i>alphar, alphai</i>	REAL for <i>sggesx</i> ; DOUBLE PRECISION for <i>dggesx</i> . Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> .
<i>alpha</i>	COMPLEX for <i>cggesx</i> ; DOUBLE COMPLEX for <i>zggesx</i> . Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	REAL for <i>sggesx</i> DOUBLE PRECISION for <i>dggesx</i> COMPLEX for <i>cggesx</i> DOUBLE COMPLEX for <i>zggesx</i> . Array, DIMENSION at least $\max(1, n)$. For real flavors: On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$ will be the generalized eigenvalues. $\text{alphar}(j) + \text{alphai}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $\text{alphai}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{alphai}(j+1)$ negative. For complex flavors:

On exit, $\alpha(j)/\beta(j)$, $j=1,\dots, n$ will be the generalized eigenvalues. $\alpha(j)$, $j=1,\dots, n$, and $\beta(j)$, $j=1,\dots, n$ are the diagonals of the complex Schur form (S,T) output by `cggesx/zggesx`. The $\beta(j)$ will be non-negative real. See also *Application Notes* below.

vsl, vsr

REAL for `sggesx`
 DOUBLE PRECISION for `dggesx`
 COMPLEX for `cggesx`
 DOUBLE COMPLEX for `zggesx`.

Arrays:

vsl(*ldvsl*,*), the second dimension of *vsl* must be at least $\max(1, n)$.

If *jobvsl* = 'V', this array will contain the left Schur vectors.

If *jobvsl* = 'N', *vsl* is not referenced.

vsr(*ldvsr*,*), the second dimension of *vsr* must be at least $\max(1, n)$.

If *jobvsr* = 'V', this array will contain the right Schur vectors.

If *jobvsr* = 'N', *vsr* is not referenced.

rconde, rcondv

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION (2) each

If *sense* = 'E' or 'B', *rconde*(1) and *rconde*(2) contain the reciprocal condition numbers for the average of the selected eigenvalues.

Not referenced if *sense* = 'N' or 'V'.

If *sense* = 'V' or 'B', *rcondv*(1) and *rcondv*(2) contain the reciprocal condition numbers for the selected deflating subspaces.

Not referenced if *sense* = 'N' or 'E'.

work(1)

On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

iwork(1)

On exit, if *info* = 0, then *iwork*(1) returns the required minimal size of *liwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*th parameter had an illegal value.
 If *info* = *i*, and
i ≤ *n*:
 the *QZ* iteration failed. (*A*, *B*) is not in Schur form, but *alphar*(*j*), *alphai*(*j*) (for real flavors), or *alpha*(*j*) (for complex flavors), and *beta*(*j*), *j*=*info*+1, ..., *n* should be correct.
i > *n*: errors that usually indicate LAPACK problems:
i = *n*+1: other than *QZ* iteration failed in ?hgeqz;
i = *n*+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy *selctg* = .TRUE..
 This could also be caused due to scaling;
i = *n*+3: reordering failed in ?tgsen.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggesx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alphai</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alpha</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>vsl</i>	Holds the matrix <i>VSL</i> of size (<i>n</i> , <i>n</i>).
<i>vsr</i>	Holds the matrix <i>VSR</i> of size (<i>n</i> , <i>n</i>).
<i>rconde</i>	Holds the vector of length (2).
<i>rcondv</i>	Holds the vector of length (2).
<i>jobvsl</i>	Restored based on the presence of the argument <i>vsl</i> as follows: <i>jobvsl</i> = 'V', if <i>vsl</i> is present, <i>jobvsl</i> = 'N', if <i>vsl</i> is omitted.
<i>jobvsr</i>	Restored based on the presence of the argument <i>vsr</i> as follows:

	$jobvsr = 'V'$, if vsr is present, $jobvsr = 'N'$, if vsr is omitted.
$sort$	Restored based on the presence of the argument $select$ as follows: $sort = 'S'$, if $select$ is present, $sort = 'N'$, if $select$ is omitted.
$sense$	Restored based on the presence of arguments $rconde$ and $rcondv$ as follows: $sense = 'B'$, if both $rconde$ and $rcondv$ are present, $sense = 'E'$, if $rconde$ is present and $rcondv$ omitted, $sense = 'V'$, if $rconde$ is omitted and $rcondv$ present, $sense = 'N'$, if both $rconde$ and $rcondv$ are omitted.

Note that there will be an error condition if $rconde$ or $rcondv$ are present and $select$ is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run or set $lwork = -1$ ($liwork = -1$).

If you choose the first option and set any of admissible $lwork$ (or $liwork$) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work, iwork$) on exit. Use this value ($work(1), iwork(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work, iwork$). This operation is called a workspace query.

Note that if you set $lwork$ ($liwork$) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients $alphar(j)/beta(j)$ and $alpha_i(j)/beta(j)$ may easily over- or underflow, and $beta(j)$ may even be zero. Thus, you should avoid simply computing the ratio. However, $alphar$ and $alpha_i$ will be always less than and usually comparable with $norm(A)$ in magnitude, and $beta$ always less than and usually comparable with $norm(B)$.

?ggeev

Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.

Syntax

FORTRAN 77:

```
call sggev(jobvl, jobvr, n, a, lda, b, ldb, alphas, alphas, beta, vl, ldvl,
vr, ldvr, work, lwork, info)

call dggev(jobvl, jobvr, n, a, lda, b, ldb, alphas, alphas, beta, vl, ldvl,
vr, ldvr, work, lwork, info)

call cggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr,
work, lwork, rwork, info)

call zggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr,
work, lwork, rwork, info)
```

Fortran 95:

```
call ggev(a, b, alphas, alphas, beta [,vl] [,vr] [,info])
call ggev(a, b, alpha, beta [, vl] [,vr] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha / \beta = \lambda$, such that $A - \lambda*B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta = 0$ and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A*v(j) = \lambda(j)*B*v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A, B) satisfies

$$u(j)^H A = \lambda(j) * u(j)^H B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

<i>jobvl</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed;</p> <p>If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.</p>
<i>jobvr</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed;</p> <p>If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.</p>
<i>n</i>	<p>INTEGER. The order of the matrices <i>A</i>, <i>B</i>, <i>vl</i>, and <i>vr</i> ($n \geq 0$).</p>
<i>a</i> , <i>b</i> , <i>work</i>	<p>REAL for <i>sggev</i> DOUBLE PRECISION for <i>dggev</i> COMPLEX for <i>cggev</i> DOUBLE COMPLEX for <i>zggev</i>.</p> <p>Arrays:</p> <p><i>a(lda,*)</i> is an array containing the n-by-n matrix <i>A</i> (first of the pair of matrices). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b(ldb,*)</i> is an array containing the n-by-n matrix <i>B</i> (second of the pair of matrices). The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The first dimension of the array <i>a</i>. Must be at least $\max(1, n)$.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of the array <i>b</i>. Must be at least $\max(1, n)$.</p>

ldvl, ldvr

INTEGER. The first dimensions of the output matrices *vl* and *vr*, respectively.

Constraints:

ldvl ≥ 1. If *jobvl* = 'V', *ldvl* ≥ max(1, *n*).

ldvr ≥ 1. If *jobvr* = 'V', *ldvr* ≥ max(1, *n*).

lwork

INTEGER.

The dimension of the array *work*.

lwork ≥ max(1, 8*n*+16) for real flavors;

lwork ≥ max(1, 2*n*) for complex flavors.

For good performance, *lwork* must generally be larger.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

rwork

REAL for *cggev*

DOUBLE PRECISION for *zggev*

Workspace array, DIMENSION at least max(1, 8*n*).

This array is used in complex flavors only.

Output Parameters

a, b

On exit, these arrays have been overwritten.

alphas, alphai

REAL for *sggev*;

DOUBLE PRECISION for *dggev*.

Arrays, DIMENSION at least max(1, *n*) each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for *cggev*;

DOUBLE COMPLEX for *zggev*.

Array, DIMENSION at least max(1, *n*). Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for *sggev*

DOUBLE PRECISION for *dggev*

COMPLEX for *cggev*

DOUBLE COMPLEX for *zggev*.

Array, DIMENSION at least max(1, *n*).

For real flavors:

On exit, $(\alpha(j) + \beta(j)i)/\beta(j)$, $j=1, \dots, n$, are the generalized eigenvalues.

If $\beta(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\beta(j+1)$ negative.

For complex flavors:

On exit, $\alpha(j)/\beta(j)$, $j=1, \dots, n$, are the generalized eigenvalues.

See also *Application Notes* below.

v_l, v_r

REAL for sggev

DOUBLE PRECISION for dggev

COMPLEX for cggev

DOUBLE COMPLEX for zggev.

Arrays:

$v_l(ldv_l, *)$; the second dimension of v_l must be at least $\max(1, n)$.

If $jobv_l = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of v_l , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobv_l = 'N'$, v_l is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = v_l(:, j)$, the j -th column of v_l .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = v_l(:, j) + i*v_l(:, j+1)$ and $u(j+1) = v_l(:, j) - i*v_l(:, j+1)$, where $i = \text{sqrt}(-1)$.

For complex flavors:

$u(j) = v_l(:, j)$, the j -th column of v_l .

$v_r(ldv_r, *)$; the second dimension of v_r must be at least $\max(1, n)$.

If $jobv_r = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of v_r , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobv_r = 'N'$, v_r is not referenced.

For real flavors:
 If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .
 If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i*vr(:, j+1)$ and $v(j+1) = vr(:, j) - i*vr(:, j+1)$.
For complex flavors:
 $v(j) = vr(:, j)$, the j -th column of vr .

work(1) On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, and
 i ≤ *n*: the QZ iteration failed. No eigenvectors have been calculated, but *alphar*(*j*), *alphai*(*j*) (for real flavors), or *alpha*(*j*) (for complex flavors), and *beta*(*j*), *j*=*info*+1, ..., *n* should be correct.
 i > *n*: errors that usually indicate LAPACK problems:
 i = *n*+1: other than QZ iteration failed in ?hgeqz;
 i = *n*+2: error return from ?tgevc.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggeev* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alphai</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alpha</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>n</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>n</i>).

<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar*(j)/*beta*(j) and *alphai*(j)/*beta*(j) may easily over- or underflow, and *beta*(j) may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with *norm(A)* in magnitude, and *beta* always less than and usually comparable with *norm(B)*.

?ggevx

Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

Syntax

FORTRAN 77:

```
call sggevx(balanc, jobvl, jobvr, sense, n, a, lda, b, ldb, alphas, alphas,

call ggevx(a, b, alphas, alphas, beta [,vl] [,vr] [,balanc] [,ilo] [,ihi] [,
lscale] [,rscale] [,abnrm] [,bbnrm] [,rconde] [,rcondv] [,info])

call ggevx(a, b, alpha, beta [, vl] [,vr] [,balanc] [,ilo] [,ihi] [,lscale]
[, rscale] [,abnrm] [,bbnrm] [,rconde] [,rcondv] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `mkl_lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A, B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *lscale*, *rscale*, *abnrm*, and *bbnrm*), reciprocal condition numbers for the eigenvalues (*rconde*), and reciprocal condition numbers for the right eigenvectors (*rcondv*).

A generalized eigenvalue for a pair of matrices (A, B) is a scalar λ or a ratio $\alpha / \beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$ and even for both being zero. The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A, B) satisfies

$$A v(j) = \lambda(j) B v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A, B) satisfies

$$u(j)^H A = \lambda(j) u(j)^H B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

<i>balanc</i>	<p>CHARACTER*1. Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed.</p> <p>If <i>balanc</i> = 'N', do not diagonally scale or permute;</p> <p>If <i>balanc</i> = 'P', permute only;</p> <p>If <i>balanc</i> = 'S', scale only;</p> <p>If <i>balanc</i> = 'B', both permute and scale.</p> <p>Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p>
<i>jobvl</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed;</p> <p>If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.</p>
<i>jobvr</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed;</p>

If *jobvr* = 'V', the right generalized eigenvectors are computed.

sense CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.
 If *sense* = 'N', none are computed;
 If *sense* = 'E', computed for eigenvalues only;
 If *sense* = 'V', computed for eigenvectors only;
 If *sense* = 'B', computed for eigenvalues and eigenvectors.

n INTEGER. The order of the matrices *A*, *B*, *vl*, and *vr* ($n \geq 0$).

a, *b*, *work* REAL for sggevx
 DOUBLE PRECISION for dggevx
 COMPLEX for cggevx
 DOUBLE COMPLEX for zggevx.

Arrays:
a(*lda*,*) is an array containing the *n*-by-*n* matrix *A* (first of the pair of matrices).
 The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) is an array containing the *n*-by-*n* matrix *B* (second of the pair of matrices).
 The second dimension of *b* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array *a*.
 Must be at least $\max(1, n)$.

ldb INTEGER. The first dimension of the array *b*.
 Must be at least $\max(1, n)$.

ldvl, *ldvr* INTEGER. The first dimensions of the output matrices *vl* and *vr*, respectively.
Constraints:
 $ldvl \geq 1$. If *jobvl* = 'V', $ldvl \geq \max(1, n)$.
 $ldvr \geq 1$. If *jobvr* = 'V', $ldvr \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*. $lwork \geq \max(1, 2*n)$;
For real flavors:

If *balanc* = 'S', or 'B', or *jobvl* = 'V', or *jobvr* = 'V', then $lwork \geq \max(1, 6*n)$;

if *sense* = 'E', or 'B', then $lwork \geq \max(1, 10*n)$;

if *sense* = 'V', or 'B', $lwork \geq (2n^2 + 8*n + 16)$.

For complex flavors:

if *sense* = 'E', $lwork \geq \max(1, 4*n)$;

if *sense* = 'V', or 'B', $lwork \geq \max(1, 2*n^2 + 2*n)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

rwork

REAL for *cggevx*

DOUBLE PRECISION for *zggevx*

Workspace array, DIMENSION at least $\max(1, 6*n)$ if

balanc = 'S', or 'B', and at least $\max(1, 2*n)$

otherwise.

This array is used in complex flavors only.

iwork

INTEGER.

Workspace array, DIMENSION at least $(n+6)$ for real flavors

and at least $(n+2)$ for complex flavors.

Not referenced if *sense* = 'E'.

bwork

LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$.

Not referenced if *sense* = 'N'.

Output Parameters

a, b

On exit, these arrays have been overwritten.

If *jobvl* = 'V' or *jobvr* = 'V' or both, then *a* contains the first part of the real Schur form of the "balanced" versions of the input *A* and *B*, and *b* contains its second part.

alphas, alphas

REAL for *sggevx*;

DOUBLE PRECISION for *dggevx*.

Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for *cggevx*;

beta

DOUBLE COMPLEX for zggevz.
 Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.
 REAL for sggevz
 DOUBLE PRECISION for dggevz
 COMPLEX for cggevz
 DOUBLE COMPLEX for zggevz.
 Array, DIMENSION at least $\max(1, n)$.

For real flavors:

On exit, $(\alpha_{\text{phar}}(j) + \alpha_{\text{phai}}(j)*i)/\beta(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

If $\alpha_{\text{phai}}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\alpha_{\text{phai}}(j+1)$ negative.

For complex flavors:

On exit, $\alpha(j)/\beta(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

See also *Application Notes* below.

vl, vr

REAL for sggevz
 DOUBLE PRECISION for dggevz
 COMPLEX for cggevz
 DOUBLE COMPLEX for zggevz.

Arrays:

$vl(ldvl,*)$; the second dimension of vl must be at least $\max(1, n)$.

If $jobvl = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of vl , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvl = 'N'$, vl is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = vl(:, j)$, the j -th column of vl .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = vl(:, j) + i*vl(:, j+1)$ and $u(j+1) = vl(:, j) - i*vl(:, j+1)$, where $i = \text{sqrt}(-1)$.

For complex flavors:

$u(j) = vl(:, j)$, the j -th column of vl .
 $vr(ldvr, *)$; the second dimension of vr must be at least $\max(1, n)$.
 If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.
 If $jobvr = 'N'$, vr is not referenced.
For real flavors:
 If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .
 If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i*vr(:, j+1)$ and $v(j+1) = vr(:, j) - i*vr(:, j+1)$.
For complex flavors:
 $v(j) = vr(:, j)$, the j -th column of vr .

ilo, ihi INTEGER. *ilo* and *ihi* are integer values such that on exit $A(i, j) = 0$ and $B(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.
 If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

lscale, rscale REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors.
 Arrays, DIMENSION at least $\max(1, n)$ each.
lscale contains details of the permutations and scaling factors applied to the left side of A and B .
 If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then
 $lscale(j) = PL(j)$, for $j = 1, \dots, ilo-1$
 $= DL(j)$, for $j = ilo, \dots, ihi$
 $= PL(j)$ for $j = ihi+1, \dots, n$.
 The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.
rscale contains details of the permutations and scaling factors applied to the right side of A and B .
 If $PR(j)$ is the index of the column interchanged with column j , and $DR(j)$ is the scaling factor applied to column j , then
 $rscale(j) = PR(j)$, for $j = 1, \dots, ilo-1$

$= DR(j), \text{ for } j = ilo, \dots, ihi$
 $= PR(j) \text{ for } j = ihi+1, \dots, n.$
 The order in which the interchanges are made is n to $ihl+1$, then 1 to $ilo-1$.

abnrm, bbnrm REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors.
 The one-norms of the balanced matrices *A* and *B*, respectively.

rconde, rcondv REAL for single precision flavors DOUBLE PRECISION for double precision flavors.
 Arrays, DIMENSION at least $\max(1, n)$ each.
 If *sense* = 'E', or 'B', *rconde* contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of *rconde* are set to the same value. Thus *rconde*(*j*), *rcondv*(*j*), and the *j*-th columns of *vl* and *vr* all correspond to the same eigenpair (but not in general the *j*-th eigenpair, unless all eigenpairs are selected).
 If *sense* = 'N', or 'V', *rconde* is not referenced.
 If *sense* = 'V', or 'B', *rcondv* contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of *rcondv* are set to the same value.
 If the eigenvalues cannot be reordered to compute *rcondv*(*j*), *rcondv*(*j*) is set to 0; this can only occur when the true value would be very small anyway.
 If *sense* = 'N', or 'E', *rcondv* is not referenced.

work(1) On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, and
 $i \leq n$:

the *QZ* iteration failed. No eigenvectors have been calculated, but *alphan*(*j*), *alphai*(*j*) (for real flavors), or *alpha*(*j*) (for complex flavors), and *beta*(*j*), *j*=*info*+1, ..., *n* should be correct.

i > *n*: errors that usually indicate LAPACK problems:

i = *n*+1: other than *QZ* iteration failed in [?hgeqz](#);

i = *n*+2: error return from [?tgevc](#).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggevx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphan</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alphai</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alpha</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>n</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>n</i>).
<i>lscale</i>	Holds the vector of length <i>n</i> .
<i>rscale</i>	Holds the vector of length <i>n</i> .
<i>rconde</i>	Holds the vector of length <i>n</i> .
<i>rcondv</i>	Holds the vector of length <i>n</i> .
<i>balanc</i>	Must be 'N', 'B', or 'P'. The default value is 'N'.
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.

sense

Restored based on the presence of arguments *rconde* and *rcondv* as follows:

sense = 'B', if both *rconde* and *rcondv* are present,
sense = 'E', if *rconde* is present and *rcondv* omitted,
sense = 'V', if *rconde* is omitted and *rcondv* present,
sense = 'N', if both *rconde* and *rcondv* are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar*(j)/*beta*(j) and *alphai*(j)/*beta*(j) may easily over- or underflow, and *beta*(j) may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with *norm*(*A*) in magnitude, and *beta* always less than and usually comparable with *norm*(*B*).

LAPACK Auxiliary and Utility Routines

5

This chapter describes the Intel® Math Kernel Library implementation of LAPACK [auxiliary](#) and [utility routines](#), as well as the [Progress Routine](#) . The library includes auxiliary routines for both real and complex data.

Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

The table below summarizes information about the available LAPACK auxiliary routines.

Table 5-1 LAPACK Auxiliary Routines

Routine Name	Data Types	Description
?lacgv	c, z	Conjugates a complex vector.
?lacrm	c, z	Multiplies a complex matrix by a square real matrix.
?lacrt	c, z	Performs a linear transformation of a pair of complex vectors.
?laesy	c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix.
?rot	c, z	Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.
?spmv	c, z	Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix
?spr	c, z	Performs the symmetrical rank-1 update of a complex symmetric packed matrix.
?symv	c, z	Computes a matrix-vector product for a complex symmetric matrix.
?syr	c, z	Performs the symmetric rank-1 update of a complex symmetric matrix.

Routine Name	Data Types	Description
i?max1	c, z	Finds the index of the vector element whose real part has maximum absolute value.
?sum1	sc, dz	Forms the 1-norm of the complex vector using the true absolute value.
?gbtf2	s, d, c, z	Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.
?gebd2	s, d, c, z	Reduces a general matrix to bidiagonal form using an unblocked algorithm.
?gehd2	s, d, c, z	Reduces a general square matrix to upper Hessenberg form using an unblocked algorithm.
?gelq2	s, d, c, z	Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.
?geql2	s, d, c, z	Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.
?geqr2	s, d, c, z	Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.
?gerq2	s, d, c, z	Computes the RQ factorization of a general rectangular matrix using an unblocked algorithm.
?gesc2	s, d, c, z	Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2 .
?getc2	s, d, c, z	Computes the LU factorization with complete pivoting of the general n-by-n matrix.
?getf2	s, d, c, z	Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).
?gtts2	s, d, c, z	Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf .
?isnan	s, d,	Tests input for NaN.

Routine Name	Data Types	Description
?lalsnan	<i>s, d,</i>	Tests input for NaN by comparing itwo arguments for inequality.
?labrd	<i>s, d, c, z</i>	Reduces the first <i>nb</i> rows and columns of a general matrix to a bidiagonal form.
?lacn2	<i>s, d, c, z</i>	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lacon	<i>s, d, c, z</i>	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lacpy	<i>s, d, c, z</i>	Copies all or part of one two-dimensional array to another.
?ladiv	<i>s, d, c, z</i>	Performs complex division in real arithmetic, avoiding unnecessary overflow.
?lae2	<i>s, d</i>	Computes the eigenvalues of a 2-by-2 symmetric matrix.
?laebz	<i>s, d</i>	Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz .
?laed0	<i>s, d, c, z</i>	Used by ?stedc . Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.
?laed1	<i>s, d</i>	Used by sstedc / dstedc . Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.
?laed2	<i>s, d</i>	Used by sstedc / dstedc . Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.
?laed3	<i>s, d</i>	Used by sstedc / dstedc . Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.

Routine Name	Data Types	Description
?laed4	s, d	Used by <code>sstedc/dstedc</code> . Finds a single root of the secular equation.
?laed5	s, d	Used by <code>sstedc/dstedc</code> . Solves the 2-by-2 secular equation.
?laed6	s, d	Used by <code>sstedc/dstedc</code> . Computes one Newton step in solution of the secular equation.
?laed7	s, d, c, z	Used by <code>?stedc</code> . Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.
?laed8	s, d, c, z	Used by <code>?stedc</code> . Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.
?laed9	s, d	Used by <code>sstedc/dstedc</code> . Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.
?laeda	s, d	Used by <code>?stedc</code> . Computes the <i>z</i> vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.
?laein	s, d, c, z	Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.
?laev2	s, d, c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.
?laexc	s, d	Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.
?lag2	s, d	Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.
?lags2	s, d	Computes 2-by-2 orthogonal matrices <i>U</i> , <i>V</i> , and <i>Q</i> , and applies them to matrices <i>A</i> and <i>B</i> such that the rows of the transformed <i>A</i> and <i>B</i> are parallel.

Routine Name	Data Types	Description
?lagtf	s, d	Computes an LU factorization of a matrix $T - \lambda I$, where T is a general tridiagonal matrix, and λ a scalar, using partial pivoting with row interchanges.
?lagtm	s, d, c, z	Performs a matrix-matrix product of the form $C = \alpha ab + \beta C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.
?lagts	s, d	Solves the system of equations $(T - \lambda I)x = y$ or $(T - \lambda I)^T x = y$, where T is a general tridiagonal matrix and λ a scalar, using the LU factorization computed by ?lagtf .
?lagv2	s, d	Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A, B) where B is upper triangular.
?lahqr	s, d, c, z	Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.
?lahrd	s, d, c, z	Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?lahr2	s, d, c, z	Reduces the specified number of first columns of a general rectangular matrix A so that elements below the specified subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?laic1	s, d, c, z	Applies one step of incremental condition estimation.
?laln2	s, d	Solves a 1-by-1 or 2-by-2 linear system of equations of the specified form.
?lals0	s, d, c, z	Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd .

Routine Name	Data Types	Description
?lalsa	s, d, c, z	Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd .
?lalsd	s, d, c, z	Uses the singular value decomposition of A to solve the least squares problem.
?lamrg	s, d	Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.
?laneg	s, d	Computes the Sturm count.
?langb	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.
?lange	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.
?langt	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.
?lanhs	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.
?lansb	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.
?lanhb	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.
?lansp	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.

Routine Name	Data Types	Description
?lanhp	<i>c, z</i>	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.
?lanst/?lanht	<i>s, d/c, z</i>	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.
?lansy	<i>s, d, c, z</i>	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.
?lanhe	<i>c, z</i>	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.
?lantb	<i>s, d, c, z</i>	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.
?lantp	<i>s, d, c, z</i>	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.
?lantr	<i>s, d, c, z</i>	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.
?lanv2	<i>s, d</i>	Computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form.
?lap11	<i>s, d, c, z</i>	Measures the linear dependence of two vectors.
?lapmt	<i>s, d, c, z</i>	Performs a forward or backward permutation of the columns of a matrix.
?lapy2	<i>s, d</i>	Returns $\sqrt{x^2 + y^2}$.
?lapy3	<i>s, d</i>	Returns $\sqrt{x^2 + y^2 + z^2}$.
?laqgb	<i>s, d, c, z</i>	Scales a general band matrix, using row and column scaling factors computed by ?gbequ .

Routine Name	Data Types	Description
?laqge	s, d, c, z	Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ .
?laqhb	c, z	Scales a Hermetian band matrix, using scaling factors computed by ?pbequ .
?laqp2	s, d, c, z	Computes a QR factorization with column pivoting of the matrix block.
?laqps	s, d, c, z	Computes a step of QR factorization with column pivoting of a real m-by-n matrix <i>A</i> by using BLAS level 3.
?laqr0	s, d, c, z	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr1	s, d, c, z	Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix <i>H</i> and specified shifts.
?laqr2	s, d, c, z	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr3	s, d, c, z	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr4	s, d, c, z	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr5	s, d, c, z	Performs a single small-bulge multi-shift QR sweep.
?laqsb	s, d, c, z	Scales a symmetric/Hermitian band matrix, using scaling factors computed by ?pbequ .
?laqsp	s, d, c, z	Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ .
?laqsy	s, d, c, z	Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ .

Routine Name	Data Types	Description
?laqtr	s, d	Solves a real quasi-triangular system of equations, or a complex quasi-triangular system of special form, in real arithmetic.
?larlv	s, d, c, z	Computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of the tridiagonal matrix $ldL^T - \sigma I$.
?lar2v	s, d, c, z	Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.
?larf	s, d, c, z	Applies an elementary reflector to a general rectangular matrix.
?larfb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
?larfg	s, d, c, z	Generates an elementary reflector (Householder matrix).
?larft	s, d, c, z	Forms the triangular factor T of a block reflector $H = I - vtv^H$.
?larfx	s, d, c, z	Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order ≤ 10 .
?largv	s, d, c, z	Generates a vector of plane rotations with real cosines and real/complex sines.
?larnv	s, d, c, z	Returns a vector of random numbers from a uniform or normal distribution.
?larra	s, d	Computes the splitting points with the specified threshold.
?larrb	s, d	Provides limited bisection to locate eigenvalues for more accuracy.
?larrc	s, d	Computes the number of eigenvalues of the symmetric tridiagonal matrix.

Routine Name	Data Types	Description
?larrd	s, d	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.
?larre	s, d	Given the tridiagonal matrix T , sets small off-diagonal elements to zero and for each unreduced block T_i , finds base representations and eigenvalues.
?larrf	s, d	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
?larrj	s, d	Performs refinement of the initial estimates of the eigenvalues of the matrix T .
?larrk	s, d	Computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy.
?larrr	s, d	Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.
?larrv	s, d, c, z	Computes the eigenvectors of the tridiagonal matrix $T = L D L^T$ given L , D and the eigenvalues of $L D L^T$.
?lartg	s, d, c, z	Generates a plane rotation with real cosine and real/complex sine.
?lartv	s, d, c, z	Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.
?laruv	s, d	Returns a vector of n random real numbers from a uniform distribution.
?larz	s, d, c, z	Applies an elementary reflector (as returned by ?tzzrf) to a general matrix.
?larzb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general matrix.
?larzt	s, d, c, z	Forms the triangular factor T of a block reflector $H = I - vtv^H$.
?las2	s, d	Computes singular values of a 2-by-2 triangular matrix.

Routine Name	Data Types	Description
?lascl	s, d, c, z	Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .
?lasd0	s, d	Computes the singular values of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e . Used by ?bdsdc .
?lasd1	s, d	Computes the SVD of an upper bidiagonal matrix B of the specified size. Used by ?bdsdc .
?lasd2	s, d	Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc .
?lasd3	s, d	Finds all square roots of the roots of the secular equation, as defined by the values in D and Z , and then updates the singular vectors by matrix multiplication. Used by ?bdsdc .
?lasd4	s, d	Computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc .
?lasd5	s, d	Computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc .
?lasd6	s, d	Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc .
?lasd7	s, d	Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc .
?lasd8	s, d	Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc .
?lasd9	s, d	Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc .

Routine Name	Data Types	Description
?lasda	s, d	Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc .
?lasdq	s, d	Computes the SVD of a real bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc .
?lasdt	s, d	Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc .
?laset	s, d, c, z	Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.
?lasq1	s, d	Computes the singular values of a real square bidiagonal matrix. Used by ?bdsqr .
?lasq2	s, d	Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the qd Array z to high relative accuracy. Used by ?bdsqr and ?stegr .
?lasq3	s, d	Checks for deflation, computes a shift and calls $dqds$. Used by ?bdsqr .
?lasq4	s, d	Computes an approximation to the smallest eigenvalue using values of d from the previous transform. Used by ?bdsqr .
?lasq5	s, d	Computes one $dqds$ transform in ping-pong form. Used by ?bdsqr and ?stegr .
?lasq6	s, d	Computes one dqd transform in ping-pong form. Used by ?bdsqr and ?stegr .
?lasr	s, d, c, z	Applies a sequence of plane rotations to a general rectangular matrix.
?lasrt	s, d	Sorts numbers in increasing or decreasing order.
?lassq	s, d, c, z	Updates a sum of squares represented in scaled form.
?lasv2	s, d	Computes the singular value decomposition of a 2-by-2 triangular matrix.

Routine Name	Data Types	Description
?laswp	s, d, c, z	Performs a series of row interchanges on a general rectangular matrix.
?lasy2	s, d	Solves the Sylvester matrix equation where the matrices are of order 1 or 2.
?lasyf	s, d, c, z	Computes a partial factorization of a real/complex symmetric matrix, using the diagonal pivoting method.
?lahef	c, z	Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.
?latbs	s, d, c, z	Solves a triangular banded system of equations.
?latdf	s, d, c, z	Uses the LU factorization of the n-by-n matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.
?latps	s, d, c, z	Solves a triangular system of equations with the matrix held in packed storage.
?latrd	s, d, c, z	Reduces the first <i>nb</i> rows and columns of a symmetric/Hermitian matrix <i>A</i> to real tridiagonal form by an orthogonal/unitary similarity transformation.
?latrs	s, d, c, z	Solves a triangular system of equations with the scale factor set to prevent overflow.
?latrz	s, d, c, z	Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.
?lauu2	s, d, c, z	Computes the product UU^H or L^HL , where <i>U</i> and <i>L</i> are upper or lower triangular matrices (unblocked algorithm).
?lauum	s, d, c, z	Computes the product UU^H or L^HL , where <i>U</i> and <i>L</i> are upper or lower triangular matrices (blocked algorithm).
?lazq3	s, d,	Checks for deflation, computes a shift and calls <i>dqds</i>
?lazq4	s, d,	Computes an approximation to the smallest eigenvalue using values of d from the previous transform.

Routine Name	Data Types	Description
?org2l/?ung2l	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by ?geqlf (unblocked algorithm).
?org2r/?ung2r	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by ?geqrf (unblocked algorithm).
?orgl2/?ungl2	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by ?gelqf (unblocked algorithm).
?org2r/?ungr2	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by ?gerqf (unblocked algorithm).
?orm2l/?unm2l	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).
?orm2r/?unm2r	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).
?orml2/?unml2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a LQ factorization determined by ?gelqf (unblocked algorithm).
?ormr2/?unmr2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RQ factorization determined by ?gerqf (unblocked algorithm).
?ormr3/?unmr3	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RZ factorization determined by ?tzzrf (unblocked algorithm).
?pbt2f	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite band matrix (unblocked algorithm).

Routine Name	Data Types	Description
?potf2	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (unblocked algorithm).
?ptts2	s, d, c, z	Solves a tridiagonal system of the form $AX=B$ using the $L D L^H$ factorization computed by ?pttrf .
?rscl	s, d, cs, zd	Multiplies a vector by the reciprocal of a real scalar.
?sygs2/?hegs2	s, d/c, z	Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).
?sytd2/?hetd2	s, d/c, z	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (unblocked algorithm).
?sytf2	s, d, c, z	Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).
?hetf2	c, z	Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).
?tgex2	s, d, c, z	Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.
?tgsy2	s, d, c, z	Solves the generalized Sylvester equation (unblocked algorithm).
?trti2	s, d, c, z	Computes the inverse of a triangular matrix (unblocked algorithm).
clag2z	c \rightarrow z	Converts a complex single precision matrix to a complex double precision matrix.
dlag2s	d \rightarrow s	Converts a double precision matrix to a single precision matrix.

Routine Name	Data Types	Description
slag2d	$s \rightarrow d$	Converts a single precision matrix to a double precision matrix.
zlag2c	$z \rightarrow c$	Converts a complex double precision matrix to a complex single precision matrix.

?lacgv

Conjugates a complex vector.

Syntax

```
call clacgv( n, x, incx )
call zlacgv( n, x, incx )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine conjugates a complex vector *x* of length *n* and increment *incx* (see “[Vector Arguments in BLAS](#)” in Appendix B).

Input Parameters

<i>n</i>	INTEGER. The length of the vector <i>x</i> ($n \geq 0$).
<i>x</i>	COMPLEX for <code>clacgv</code> COMPLEX*16 for <code>zlacgv</code> . Array, dimension $(1+(n-1) * incx)$. Contains the vector of length <i>n</i> to be conjugated.
<i>incx</i>	INTEGER. The spacing between successive elements of <i>x</i> .

Output Parameters

<i>x</i>	On exit, overwritten with <code>conjg(x)</code> .
----------	---------------------------------------------------

zlacrm

Multiplies a complex matrix by a square real matrix.

Syntax

```
call clacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

```
call zlacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine performs a simple matrix-matrix multiplication of the form

$$C = A * B,$$

where A is m -by- n and complex, B is n -by- n and real, C is m -by- n and complex.

Input Parameters

m	INTEGER. The number of rows of the matrix A and of the matrix C ($m \geq 0$).
n	INTEGER. The number of columns and rows of the matrix B and the number of columns of the matrix C ($n \geq 0$).
a	COMPLEX for <code>clacrm</code> COMPLEX*16 for <code>zlacrm</code> Array, DIMENSION (lda , n). Contains the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a , $lda \geq \max(1, m)$.
b	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code> Array, DIMENSION (ldb , n). Contains the n -by- n matrix B .

<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> , $ldb \geq \max(1, n)$.
<i>ldc</i>	INTEGER. The leading dimension of the output array <i>c</i> , $ldc \geq \max(1, n)$.
<i>rwork</i>	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code> Workspace array, DIMENSION $(2*m*n)$.

Output Parameters

<i>c</i>	COMPLEX for <code>clacrm</code> COMPLEX*16 for <code>zlacrm</code> Array, DIMENSION (ldc, n) . Contains the m -by- n matrix <i>c</i> .
----------	----------------------------------------------------------------------------------------------------------------------------------------------------

?lacrt

Performs a linear transformation of a pair of complex vectors.

Syntax

```
call clacrt( n, cx, incx, cy, incy, c, s )
call zlacrt( n, cx, incx, cy, incy, c, s )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine performs the following transformation

$$\begin{pmatrix} c & s \\ -s & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \Rightarrow \begin{pmatrix} x \\ y \end{pmatrix},$$

where *c*, *s* are complex scalars and *x*, *y* are complex vectors.

Input Parameters

<i>n</i>	INTEGER. The number of elements in the vectors <i>cx</i> and <i>cy</i> ($n \geq 0$).
<i>cx</i> , <i>cy</i>	COMPLEX for <code>clacrt</code> COMPLEX*16 for <code>zlacrt</code> Arrays, dimension (<i>n</i>). Contain input vectors <i>x</i> and <i>y</i> , respectively.
<i>incx</i>	INTEGER. The increment between successive elements of <i>cx</i> .
<i>incy</i>	INTEGER. The increment between successive elements of <i>cy</i> .
<i>c</i> , <i>s</i>	COMPLEX for <code>clacrt</code> COMPLEX*16 for <code>zlacrt</code> Complex scalars that define the transform matrix

$$\begin{bmatrix} c & s \\ -s & c \end{bmatrix}$$

Output Parameters

<i>cx</i>	On exit, overwritten with $c*x + s*y$.
<i>cy</i>	On exit, overwritten with $-s*x + c*y$.

?laesy

Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix, and checks that the norm of the matrix of eigenvectors is larger than a threshold value.

Syntax

```
call claesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
call zlaesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix},$$

provided the norm of the matrix of eigenvectors is larger than some threshold value.

rt1 is the eigenvalue of larger absolute value, and *rt2* of smaller absolute value. If the eigenvectors are computed, then on return (*cs1*, *sn1*) is the unit eigenvector for *rt1*, hence

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -sn1 \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

Input Parameters

a, *b*, *c* COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 Elements of the input matrix.

Output Parameters

rt1, *rt2* COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 Eigenvalues of larger and smaller modulus, respectively.

evscal COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 The complex value by which the eigenvector matrix was scaled to make it orthonormal. If *evscal* is zero, the eigenvectors were not computed. This means one of two things: the 2-by-2 matrix could not be diagonalized, or the norm of the matrix of eigenvectors before scaling was larger than the threshold value `thresh` (set to 0.1E0).

cs1, sn1 COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 If *evscal* is not zero, then (*cs1, sn1*) is the unit right
 eigenvector for *rtl*.

?rot

Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.

Syntax

```
call crot( n, cx, incx, cy, incy, c, s )
call zrot( n, cx, incx, cy, incy, c, s )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine applies a plane rotation, where the cosine (*c*) is real and the sine (*s*) is complex, and the vectors *cx* and *cy* are complex. This routine has its real equivalents in BLAS (see [?rot](#) in Chapter 2).

Input Parameters

<i>n</i>	INTEGER. The number of elements in the vectors <i>cx</i> and <i>cy</i> .
<i>cx, cy</i>	COMPLEX for <code>crot</code> COMPLEX*16 for <code>zrot</code> Arrays of dimension (<i>n</i>), contain input vectors <i>x</i> and <i>y</i> , respectively.
<i>incx</i>	INTEGER. The increment between successive elements of <i>cx</i> .
<i>incy</i>	INTEGER. The increment between successive elements of <i>cy</i> .
<i>c</i>	REAL for <code>crot</code> DOUBLE PRECISION for <code>zrot</code>
<i>s</i>	COMPLEX for <code>crot</code>

COMPLEX*16 for zrot
Values that define a rotation

$$\begin{bmatrix} c & s \\ -\text{conjg}(s) & c \end{bmatrix}$$

where $c*c + s*\text{conjg}(s) = 1.0$.

Output Parameters

<i>cx</i>	On exit, overwritten with $c*x + s*y$.
<i>cy</i>	On exit, overwritten with $-\text{conjg}(s)*x + c*y$.

?spmv

Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix.

Syntax

```
call cspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
call zspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The ?spmv routines perform a matrix-vector operation defined as

$y := \alpha*a*x + \beta*y,$

where:

alpha and *beta* are complex scalars,

x and *y* are *n*-element complex vectors

a is an *n*-by-*n* complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see ?spmv in Chapter 2).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>a</i> is supplied in the packed array <i>ap</i>.</p> <p>If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>.</p> <p>If <i>uplo</i> = 'L' or 'l', the lower triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>.</p>
<i>n</i>	<p>INTEGER.</p> <p>Specifies the order of the matrix <i>a</i>.</p> <p>The value of <i>n</i> must be at least zero.</p>
<i>alpha, beta</i>	<p>COMPLEX for <i>cspmv</i> COMPLEX*16 for <i>zspmv</i></p> <p>Specify complex scalars <i>alpha</i> and <i>beta</i>. When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.</p>
<i>ap</i>	<p>COMPLEX for <i>cspmv</i> COMPLEX*16 for <i>zspmv</i></p> <p>Array, DIMENSION at least $((n*(n+1))/2)$. Before entry, with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>A</i>(1, 1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>A</i>(1, 2) and <i>A</i>(2, 2) respectively, and so on. Before entry, with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1, 1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(2, 1) and <i>a</i>(3, 1) respectively, and so on.</p>
<i>x</i>	<p>COMPLEX for <i>cspmv</i> COMPLEX*16 for <i>zspmv</i></p> <p>Array, DIMENSION at least $(1 + (n-1)*abs(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.</p>
<i>y</i>	<p>COMPLEX for <i>cspmv</i></p>

COMPLEX*16 for `zspmv`

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$.

Before entry, the incremented array y must contain the n -element vector y .

incy

INTEGER. Specifies the increment for the elements of y . The value of incy must not be zero.

Output Parameters

y

Overwritten by the updated vector y .

?spr

Performs the symmetrical rank-1 update of a complex symmetric packed matrix.

Syntax

`call cspr(uplo, n, alpha, x, incx, ap)`

`call zspr(uplo, n, alpha, x, incx, ap)`

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The `?spr` routines perform a matrix-vector operation defined as

$a := \alpha * x * \text{conjg}(x') + a,$

where:

α is a complex scalar

x is an n -element complex vector

a is an n -by- n complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see `?spr` in Chapter 2).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>a</i> is supplied in the packed array <i>ap</i>, as follows:</p> <p>If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>.</p> <p>If <i>uplo</i> = 'L' or 'l', the lower triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>.</p>
<i>n</i>	<p>INTEGER.</p> <p>Specifies the order of the matrix <i>a</i>.</p> <p>The value of <i>n</i> must be at least zero.</p>
<i>alpha</i>	<p>COMPLEX for <i>cspr</i></p> <p>COMPLEX*16 for <i>zspr</i></p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>x</i>	<p>COMPLEX for <i>cspr</i></p> <p>COMPLEX*16 for <i>zspr</i></p> <p>Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.</p>
<i>ap</i>	<p>COMPLEX for <i>cspr</i></p> <p>COMPLEX*16 for <i>zspr</i></p> <p>Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry, with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>A</i>(1, 1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>A</i>(1, 2) and <i>A</i>(2, 2) respectively, and so on.</p> <p>Before entry, with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1, 1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(2, 1) and <i>a</i>(3, 1) respectively, and so on.</p>

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Output Parameters

ap

With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.

With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.

?symv

Computes a matrix-vector product for a complex symmetric matrix.

Syntax

```
call csymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
```

```
call zsymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine performs the matrix-vector operation defined as

$$y := \alpha a x + \beta y,$$

where:

alpha and *beta* are complex scalars

x and *y* are *n*-element complex vectors

a is an *n*-by-*n* symmetric complex matrix.

These routines have their real equivalents in BLAS (see [?symv](#) in Chapter 2).

Input Parameters

uplo

CHARACTER*1. Specifies whether the upper or lower triangular part of the array *a* is used:

	<p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array <i>a</i> is used.</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix <i>a</i>. The value of <i>n</i> must be at least zero.</p>
<i>alpha, beta</i>	<p>COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Specify the scalars <i>alpha</i> and <i>beta</i>. When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.</p>
<i>a</i>	<p>COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced.</p>
<i>lda</i>	<p>INTEGER. Specifies the first dimension of <i>A</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.</p>
<i>x</i>	<p>COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.</p>
<i>y</i>	<p>COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i>-element vector <i>y</i>.</p>

incy INTEGER. Specifies the increment for the elements of *y*. The value of *incy* must not be zero.

Output Parameters

y Overwritten by the updated vector *y*.

?syr

Performs the symmetric rank-1 update of a complex symmetric matrix.

Syntax

```
call csyr( uplo, n, alpha, x, incx, a, lda )
```

```
call zsyr( uplo, n, alpha, x, incx, a, lda )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine performs the symmetric rank 1 operation defined as

$$a := \alpha x x^H + a,$$

where:

alpha is a complex scalar

x is an *n*-element complex vector

a is an *n*-by-*n* complex symmetric matrix.

These routines have their real equivalents in BLAS (see [?syr](#) in Chapter 2).

Input Parameters

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the array *a* is used:
 If *uplo* = 'U' or 'u', then the upper triangular part of the array *a* is used.
 If *uplo* = 'L' or 'l', then the lower triangular part of the array *a* is used.

<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for <i>csyr</i> COMPLEX*16 for <i>zsyr</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for <i>csyr</i> COMPLEX*16 for <i>zsyr</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>a</i>	COMPLEX for <i>csyr</i> COMPLEX*16 for <i>zsyr</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix.
----------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

i?max1

Finds the index of the vector element whose real part has maximum absolute value.

Syntax

```
index = icmax1( n, cx, incx )
```

```
index = izmax1( n, cx, incx )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

Given a complex vector `cx`, the `i?max1` functions return the index of the vector element whose real part has maximum absolute value. These functions are based on the BLAS functions `icamax/izamax`, but using the absolute value of the real part. They are designed for use with `clacon/zlacon`.

Input Parameters

<code>n</code>	INTEGER. Specifies the number of elements in the vector <code>cx</code> .
<code>cx</code>	COMPLEX for <code>icmax1</code> COMPLEX*16 for <code>izmax1</code> Array, DIMENSION at least $(1+(n-1)*abs(incx))$. Contains the input vector.
<code>incx</code>	INTEGER. Specifies the spacing between successive elements of <code>cx</code> .

Output Parameters

<code>index</code>	INTEGER. Contains the index of the vector element whose real part has maximum absolute value.
--------------------	-----------------------------------------------------------------------------------------------

?sum1

Forms the 1-norm of the complex vector using the true absolute value.

Syntax

```
res = scsum1( n, cx, incx )
```

```
res = dzsum1( n, cx, incx )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

Given a complex vector `cx`, `scsum1/dzsum1` functions take the sum of the absolute values of vector elements and return a single/DOUBLE PRECISION result, respectively. These functions are based on `scasum/dzasum` from Level 1 BLAS, but use the true absolute value and were designed for use with `clacon/zlacon`.

Input Parameters

<code>n</code>	INTEGER. Specifies the number of elements in the vector <code>cx</code> .
<code>cx</code>	COMPLEX for <code>scsum1</code> COMPLEX*16 for <code>dzsum1</code> Array, DIMENSION at least $(1 + (n-1) * \text{abs}(incx))$. Contains the input vector whose elements will be summed.
<code>incx</code>	INTEGER. Specifies the spacing between successive elements of <code>cx</code> ($incx > 0$).

Output Parameters

<code>res</code>	REAL for <code>scsum1</code> DOUBLE PRECISION for <code>dzsum1</code> Contains the sum of absolute values.
------------------	------------------------------------------------------------------------------------------------------------------

?gbtf2

Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.

Syntax

```
call sgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call dgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call cgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call zgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine forms the *LU* factorization of a general real/complex *m*-by-*n* band matrix *A* with *kl* sub-diagonals and *ku* super-diagonals. The routine uses partial pivoting with row interchanges and implements the unblocked version of the algorithm, calling Level 2 BLAS. See also [?gbtrf](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ($ku \geq 0$).
<i>ab</i>	REAL for <code>sgbtf2</code> DOUBLE PRECISION for <code>dgbtf2</code> COMPLEX for <code>cgbtf2</code> COMPLEX*16 for <code>zgbtf2</code> . Array, DIMENSION (<i>ldab</i> ,*). The array <i>ab</i> contains the matrix <i>A</i> in band storage (see Matrix Arguments). The second dimension of <i>ab</i> must be at least $\max(1, n)$.

ldab INTEGER. The first dimension of the array *ab*.
 $(ldab \geq 2kl + ku + 1)$

Output Parameters

ab Overwritten by details of the factorization. The diagonal and $kl + ku$ super-diagonals of U are stored in the first $1 + kl + ku$ rows of *ab*. The multipliers used during the factorization are stored in the next kl rows.

ipiv INTEGER.
 Array, DIMENSION at least $\max(1, \min(m, n))$.
 The pivot indices: row i was interchanged with row $ipiv(i)$.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = $-i$, the i -th parameter had an illegal value.
 If *info* = i , u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

?gebd2

Reduces a general matrix to bidiagonal form using an unblocked algorithm.

Syntax

```
call sgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call dgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call cgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call zgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine reduces a general m -by- n matrix A to upper or lower bidiagonal form B by an orthogonal (unitary) transformation: $Q'^* A P = B$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. if $m \geq n$,

$$Q = H(1) * H(2) * \dots * H(n), \text{ and } P = G(1) * G(2) * \dots * G(n-1)$$

if $m < n$,

$$Q = H(1) * H(2) * \dots * H(m-1), \text{ and } P = G(1) * G(2) * \dots * G(m)$$

Each $H(i)$ and $G(i)$ has the form

$$H(i) = I - \tau_{uq} * v * v' \text{ and } G(i) = I - \tau_{up} * u * u'$$

where τ_{uq} and τ_{up} are scalars (real for `sgebd2/dgebd2`, complex for `cgebd2/zgebd2`), and v and u are vectors (real for `sgebd2/dgebd2`, complex for `cgebd2/zgebd2`).

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgebd2</code> DOUBLE PRECISION for <code>dgebd2</code> COMPLEX for <code>cgebd2</code> COMPLEX*16 for <code>zgebd2</code> . Arrays: $a(lda, *)$ contains the m -by- n general matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$. $work(*)$ is a workspace array, the dimension of $work$ must be at least $\max(1, m, n)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a	if $m \geq n$, the diagonal and first super-diagonal of a are overwritten with the upper bidiagonal matrix B . Elements below the diagonal, with the array τ_{uq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the first superdiagonal, with the array τ_{up} , represent the orthogonal/unitary matrix P as a product of elementary reflectors.
-----	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

if $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B . Elements below the first subdiagonal, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the diagonal, with the array taup , represent the orthogonal/unitary matrix P as a product of elementary reflectors.

d

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$.Contains the diagonal elements of the bidiagonal matrix B : $d(i) = a(i, i)$.*e*

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Array,

DIMENSION at least $\max(1, \min(m, n) - 1)$.

Contains the off-diagonal elements of the bidiagonal matrix

 B :if $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$;if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$.*tauq, taup*

REAL for sgebd2

DOUBLE PRECISION for dgebd2

COMPLEX for cgebd2

COMPLEX*16 for zgebd2.

Arrays, DIMENSION at least $\max(1, \min(m, n))$.Contain scalar factors of the elementary reflectors which represent orthogonal/unitary matrices Q and P , respectively.*info*

INTEGER.

If $\text{info} = 0$, the execution is successful.If $\text{info} = -i$, the i th parameter had an illegal value.

?gehd2

Reduces a general square matrix to upper Hessenberg form using an unblocked algorithm.

Syntax

```
call sgehd2( n, ilo, ihi, a, lda, tau, work, info )
call dgehd2( n, ilo, ihi, a, lda, tau, work, info )
call cgehd2( n, ilo, ihi, a, lda, tau, work, info )
call zgehd2( n, ilo, ihi, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine reduces a real/complex general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $Q^* A Q = H$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*.

Input Parameters

n	INTEGER The order of the matrix A ($n \geq 0$).
ilo, ihi	INTEGER. It is assumed that A is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$. If A has been output by ?gebal, then ilo and ihi must contain the values returned by that routine. Otherwise they should be set to $ilo = 1$ and $ihi = n$. Constraint: $1 \leq ilo \leq ihi \leq \max(1, n)$.
$a, work$	REAL for sgehd2 DOUBLE PRECISION for dgehd2 COMPLEX for cgehd2 COMPLEX*16 for zgehd2. Arrays: a ($lda, *$) contains the n -by- n matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$.

work (*n*) is a workspace array.
lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

Output Parameters

a On exit, the upper triangle and the first subdiagonal of *A* are overwritten with the upper Hessenberg matrix *H* and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors. See *Application Notes* below.

tau REAL for sgehd2
 DOUBLE PRECISION for dgehd2
 COMPLEX for cgehd2
 COMPLEX*16 for zgehd2.
 Array, DIMENSION at least $\max(1, n-1)$.
 Contains the scalar factors of elementary reflectors. See *Application Notes* below.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The matrix *Q* is represented as a product of (*ihi* - *ilo*) elementary reflectors

$$Q = H(ilo) * H(ilo + 1) * \dots * H(ihi - 1)$$

Each *H*(*i*) has the form

$$H(i) = I - \tau v v'$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$.

On exit, $v(i+2:ihi)$ is stored in $a(i+2:ihi, i)$ and *tau* in $\tau(i)$.

The contents of *a* are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

$$\begin{array}{cc}
 \text{on entry} & \text{on exit} \\
 \left[\begin{array}{cccccc} a & a & a & a & a & a \\ & a & a & a & a & a \\ & & a & a & a & a \\ & & & a & a & a \\ & & & & a & a \\ & & & & & a \end{array} \right] & \left[\begin{array}{cccccc} a & a & h & h & h & h \\ & a & h & h & h & h \\ & & h & h & h & h \\ & & v_2 & h & h & h \\ & & v_2 & v_3 & h & h \\ & & v_2 & v_3 & v_4 & h \\ & & & & & a \end{array} \right]
 \end{array}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?sgelq2

Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgelq2( m, n, a, lda, tau, work, info )
call dgelq2( m, n, a, lda, tau, work, info )
call cgelq2( m, n, a, lda, tau, work, info )
call zgelq2( m, n, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes an LQ factorization of a real/complex m -by- n matrix A as $A = L^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(k) \dots H(2) H(1)$ (or $Q = H(k)^T \dots H(2)^T H(1)^T$ for complex flavors), where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:n)$ is stored in $a(i, i+1:n)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for `sgelq2`
 DOUBLE PRECISION for `dgelq2`
 COMPLEX for `cgelq2`
 COMPLEX*16 for `zgelq2`.
 Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$.
 $work(m)$ is a workspace array.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:
 on exit, the elements on and below the diagonal of the array a contain the m -by- $\min(n, m)$ lower trapezoidal matrix L (L is lower triangular if $n \geq m$); the elements above the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors.

tau REAL for `sgelq2`
 DOUBLE PRECISION for `dgelq2`
 COMPLEX for `cgelq2`
 COMPLEX*16 for `zgelq2`.
 Array, DIMENSION at least $\max(1, \min(m, n))$.
 Contains scalar factors of the elementary reflectors.

info INTEGER.
 If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?geql2

Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgeql2( m, n, a, lda, tau, work, info )
call dgeql2( m, n, a, lda, tau, work, info )
call cgeql2( m, n, a, lda, tau, work, info )
call zgeql2( m, n, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes a QL factorization of a real/complex m -by- n matrix A as $A = Q * L$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(k) * \dots * H(2) * H(1)$, where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$.

On exit, $v(1:m-k+i-1)$ is stored in $a(1:m-k+i-1, n-k+i)$.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for sgeql2 DOUBLE PRECISION for dgeql2 COMPLEX for cgeql2

COMPLEX*16 for `zgeql2`.

Arrays:

`a(lda,*)` contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

`work(m)` is a workspace array.

`lda`

INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

`a`

Overwritten by the factorization data as follows:

on exit, if $m \geq n$, the lower triangle of the subarray

`a(m-n+1:m, 1:n)` contains the n -by- n lower triangular matrix L ; if $m < n$, the elements on and below the $(n-m)$ th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array `tau`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

`tau`

REAL for `sgeql2`

DOUBLE PRECISION for `dgeql2`

COMPLEX for `cgeql2`

COMPLEX*16 for `zgeql2`.

Array, DIMENSION at least $\max(1, \min(m, n))$.

Contains scalar factors of the elementary reflectors.

`info`

INTEGER.

If `info` = 0, the execution is successful.

If `info` = $-i$, the i -th parameter had an illegal value.

?geqr2

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgeqr2( m, n, a, lda, tau, work, info )
call dgeqr2( m, n, a, lda, tau, work, info )
call cgeqr2( m, n, a, lda, tau, work, info )
call zgeqr2( m, n, a, lda, tau, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes a QR factorization of a real/complex m -by- n matrix A as $A = Q^*R$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(1) * H(2) * \dots * H(k)$, where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v'$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:m)$ is stored in $a(i+1:m, i)$.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgeqr2</code> DOUBLE PRECISION for <code>dgeqr2</code> COMPLEX for <code>cgeqr2</code> COMPLEX*16 for <code>zgeqr2</code> . Arrays:

$a(lda, *)$ contains the m -by- n matrix A .
 The second dimension of a must be at least $\max(1, n)$.
 $work(n)$ is a workspace array.
 lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:
 on exit, the elements on and above the diagonal of the array
 a contain the $\min(n, m)$ -by- n upper trapezoidal matrix R (R
 is upper triangular if $m \geq n$); the elements below the
 diagonal, with the array tau , represent the
 orthogonal/unitary matrix Q as a product of elementary
 reflectors.

tau REAL for sgerq2
 DOUBLE PRECISION for dgerq2
 COMPLEX for cgerq2
 COMPLEX*16 for zgerq2.
 Array, DIMENSION at least $\max(1, \min(m, n))$.
 Contains scalar factors of the elementary reflectors.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

?gerq2

Computes the RQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgerq2( m, n, a, lda, tau, work, info )
call dgerq2( m, n, a, lda, tau, work, info )
call cgerq2( m, n, a, lda, tau, work, info )
call zgerq2( m, n, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes a RQ factorization of a real/complex m -by- n matrix A as $A = R^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$$Q = H(1) * H(2) * \dots * H(k), \text{ where } k = \min(m, n)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$.

On exit, $v(1:n-k+i-1)$ is stored in $a(m-k+i, 1:n-k+i-1)$.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for sgerq2 DOUBLE PRECISION for dgerq2 COMPLEX for cgerq2 COMPLEX*16 for zgerq2. Arrays: $a(lda, *)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $work(m)$ is a workspace array.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a	Overwritten by the factorization data as follows: on exit, if $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the m -by- m upper triangular matrix R ; if $m > n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ;
-----	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

the remaining elements, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors.

tau REAL for sgerq2
 DOUBLE PRECISION for dgerq2
 COMPLEX for cgerq2
 COMPLEX*16 for zgerq2.
 Array, DIMENSION at least $\max(1, \min(m, n))$.
 Contains scalar factors of the elementary reflectors.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

?gesc2

Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2.

Syntax

```
call sgetc2( n, a, lda, rhs, ipiv, jpiv, scale )
call dgetc2( n, a, lda, rhs, ipiv, jpiv, scale )
call cgetc2( n, a, lda, rhs, ipiv, jpiv, scale )
call zgetc2( n, a, lda, rhs, ipiv, jpiv, scale )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine solves a system of linear equations

$$A \cdot X = scale \cdot RHS$$

with a general n -by- n matrix *A* using the *LU* factorization with complete pivoting computed by [?getc2](#).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> .
<i>a, rhs</i>	REAL for <i>sgetc2</i> DOUBLE PRECISION for <i>dgetc2</i> COMPLEX for <i>cgetc2</i> COMPLEX*16 for <i>zgetc2</i> . Arrays: <i>a(lda,*)</i> contains the <i>LU</i> part of the factorization of the <i>n</i> -by- <i>n</i> matrix <i>A</i> computed by <i>?getc2</i> : $A = P * L * U * Q$. The second dimension of <i>a</i> must be at least $\max(1, n)$; <i>rhs(n)</i> contains on entry the right hand side vector for the system of equations.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq i \leq n$, row <i>i</i> of the matrix has been interchanged with row <i>ipiv(i)</i> .
<i>jpiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq j \leq n$, column <i>j</i> of the matrix has been interchanged with column <i>jpiv(j)</i> .

Output Parameters

<i>rhs</i>	On exit, overwritten with the solution vector <i>x</i> .
<i>scale</i>	REAL for <i>sgetc2/cgetc2</i> DOUBLE PRECISION for <i>dgetc2/zgetc2</i> Contains the scale factor. <i>scale</i> is chosen in the range $0 \leq scale \leq 1$ to prevent overflow in the solution.

?getc2

Computes the LU factorization with complete pivoting of the general n -by- n matrix.

Syntax

```
call sgetc2( n, a, lda, ipiv, jpiv, info )
call dgetc2( n, a, lda, ipiv, jpiv, info )
call cgetc2( n, a, lda, ipiv, jpiv, info )
call zgetc2( n, a, lda, ipiv, jpiv, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes an LU factorization with complete pivoting of the n -by- n matrix A . The factorization has the form $A = P * L * U * Q$, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

The LU factorization computed by this routine is used by [?latdf](#) to compute a contribution to the reciprocal Dif-estimate.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
a	REAL for <code>sgetc2</code> DOUBLE PRECISION for <code>dgetc2</code> COMPLEX for <code>cgetc2</code> COMPLEX*16 for <code>zgetc2</code> . Array <code>a(lda,*)</code> contains the n -by- n matrix A to be factored. The second dimension of a must be at least <code>max(1, n)</code> ;
lda	INTEGER. The first dimension of a ; at least <code>max(1, n)</code> .

Output Parameters

<i>a</i>	On exit, the factors <i>L</i> and <i>U</i> from the factorization $A = P^*L^*U^*Q$; the unit diagonal elements of <i>L</i> are not stored. If $U(k, k)$ appears to be less than <i>smin</i> , $U(k, k)$ is given the value of <i>smin</i> , that is giving a nonsingular perturbed system.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq i \leq n$, row <i>i</i> of the matrix has been interchanged with row <i>ipiv</i> (<i>i</i>).
<i>jpiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq j \leq n$, column <i>j</i> of the matrix has been interchanged with column <i>jpiv</i> (<i>j</i>).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>k</i> > 0, $U(k, k)$ is likely to produce overflow if we try to solve for <i>x</i> in $A^*x = b$. So <i>U</i> is perturbed to avoid the overflow.

?getf2

Computes the LU factorization of a general m-by-n matrix using partial pivoting with row interchanges (unblocked algorithm).

Syntax

```
call sgetf2( m, n, a, lda, ipiv, info )
call dgetf2( m, n, a, lda, ipiv, info )
call cgetf2( m, n, a, lda, ipiv, info )
call zgetf2( m, n, a, lda, ipiv, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the LU factorization of a general m -by- n matrix A using partial pivoting with row interchanges. The factorization has the form

$$A = P * L * U$$

where p is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
a	REAL for sgetf2 DOUBLE PRECISION for dgetf2 COMPLEX for cgetf2 COMPLEX*16 for zgetf2. Array, DIMENSION ($lda, *$). Contains the matrix A to be factored. The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a	Overwritten by L and U . The unit diagonal elements of L are not stored.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv(i)$.
$info$	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i > 0$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

?gtts2

Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf.

Syntax

```
call sgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call dgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call cgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call zgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine solves for X one of the following systems of linear equations with multiple right hand sides:

$A^*X = B$, $A^T * X = B$, or $A^H * X = B$ (for complex matrices only), with a tridiagonal matrix A using the LU factorization computed by `?gttrf`.

Input Parameters

<code>itrans</code>	INTEGER. Must be 0, 1, or 2. Indicates the form of the equations to be solved: If <code>itrans</code> = 0, then $A^*X = B$ (no transpose). If <code>itrans</code> = 1, then $A^T * X = B$ (transpose). If <code>itrans</code> = 2, then $A^H * X = B$ (conjugate transpose).
<code>n</code>	INTEGER. The order of the matrix A ($n \geq 0$).
<code>nrhs</code>	INTEGER. The number of right-hand sides, i.e., the number of columns in B ($nrhs \geq 0$).
<code>dl,d,du,du2,b</code>	REAL for <code>sgtts2</code> DOUBLE PRECISION for <code>dgtts2</code> COMPLEX for <code>cgtts2</code> COMPLEX*16 for <code>zgtts2</code> .

Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$, $du2(n-2)$,
 $b(ldb, nrhs)$.

The array dl contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .

The array d contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A .

The array du contains the $(n-1)$ elements of the first super-diagonal of U .

The array $du2$ contains the $(n-2)$ elements of the second super-diagonal of U .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

ldb INTEGER. The leading dimension of b ; must be $ldb \geq \max(1, n)$.

ipiv INTEGER.
 Array, DIMENSION (n) .
 The pivot indices array, as returned by `?gttrf`.

Output Parameters

b Overwritten by the solution matrix X .

?isnan

Tests input for NaN.

Syntax

`val = sisnan(sin)`

`val = disnan(din)`

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

This logical routine returns `.TRUE.` if its argument is NaN, and `.FALSE.` otherwise.

Input Parameters

<i>sin</i>	REAL for <code>sisnan</code> Input to test for NaN.
<i>din</i>	DOUBLE PRECISION for <code>disnan</code> Input to test for NaN.

Output Parameters

<i>val</i>	Logical. Result of the test.
------------	------------------------------

?laisnan

Tests input for NaN.

Syntax

```
val = slaisnan( sin1, sin2 )
val = dlaisnan( din1, din2 )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

This logical routine checks for NaNs (NaN stands for 'Not A Number') by comparing its two arguments for inequality. NaN is the only floating-point value where `NaN ≠ NaN` returns `.TRUE.`. To check for NaNs, pass the same variable as both arguments.

This routine is not for general use. It exists solely to avoid over-optimization in `?isnan`.

Input Parameters

<i>sin1, sin2</i>	REAL for <code>sisnan</code> Two numbers to compare for inequality.
<i>din2, din2</i>	DOUBLE PRECISION for <code>disnan</code> Two numbers to compare for inequality.

Output Parameters

<i>val</i>	Logical. Result of the comparison.
------------	------------------------------------

?labrd

Reduces the first nb rows and columns of a general matrix to a bidiagonal form.

Syntax

```
call slabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call dlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call clabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call zlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine reduces the first nb rows and columns of a general m -by- n matrix A to upper or lower bidiagonal form by an orthogonal/unitary transformation $Q' * A * P$, and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A .

if $m \geq n$, A is reduced to upper bidiagonal form; if $m < n$, to lower bidiagonal form.

The matrices Q and P are represented as products of elementary reflectors: $Q = H(1) * (2) * \dots * H(nb)$, and $P = G(1) * G(2) * \dots * G(nb)$

Each $H(i)$ and $G(i)$ has the form

$$H(i) = I - \tau_{auq} * v * v' \text{ and } G(i) = I - \tau_{aup} * u * u'$$

where τ_{auq} and τ_{aup} are scalars, and v and u are vectors.

The elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U' which are needed, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $A := A - V * Y' - X * U'$.

This is an auxiliary routine called by [?gebrd](#).

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

<i>nb</i>	INTEGER. The number of leading rows and columns of <i>A</i> to be reduced.
<i>a</i>	REAL for <code>slabrd</code> DOUBLE PRECISION for <code>dlabrd</code> COMPLEX for <code>clabrd</code> COMPLEX*16 for <code>zlabrd</code> . Array <i>a</i> (<i>lda</i> ,*) contains the matrix <i>A</i> to be reduced. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; must beat least $\max(1, m)$.
<i>ldy</i>	INTEGER. The first dimension of the output array <i>y</i> ; must beat least $\max(1, n)$.

Output Parameters

<i>a</i>	On exit, the first <i>nb</i> rows and columns of the matrix are overwritten; the rest of the array is unchanged. if $m \geq n$, elements on and below the diagonal in the first <i>nb</i> columns, with the array <i>tauq</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors; and elements above the diagonal in the first <i>nb</i> rows, with the array <i>taup</i> , represent the orthogonal/unitary matrix <i>P</i> as a product of elementary reflectors. if $m < n$, elements below the diagonal in the first <i>nb</i> columns, with the array <i>tauq</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors, and elements on and above the diagonal in the first <i>nb</i> rows, with the array <i>taup</i> , represent the orthogonal/unitary matrix <i>P</i> as a product of elementary reflectors.
<i>d</i> , <i>e</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays, DIMENSION (<i>nb</i>) each. The array <i>d</i> contains the diagonal elements of the first <i>nb</i> rows and columns of the reduced matrix: $d(i) = a(i, i)$.

The array e contains the off-diagonal elements of the first nb rows and columns of the reduced matrix.

$tauq, taup$ REAL for slabrd
 DOUBLE PRECISION for dlabrd
 COMPLEX for clabrd
 COMPLEX*16 for zlabrd.
 Arrays, DIMENSION (nb) each. Contain scalar factors of the elementary reflectors which represent the orthogonal/unitary matrices Q and P , respectively.

x, y REAL for slabrd
 DOUBLE PRECISION for dlabrd
 COMPLEX for clabrd
 COMPLEX*16 for zlabrd.
 Arrays, dimension $x(ldx, nb)$, $y(ldy, nb)$.
 The array x contains the m -by- nb matrix X required to update the unreduced part of A .
 The array y contains the n -by- nb matrix Y required to update the unreduced part of A .

Application Notes

if $m \geq n$, then for the elementary reflectors $H(i)$ and $G(i)$,

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in $a(i:m, i)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $a(i, i+1:n)$;

$tauq$ is stored in $tauq(i)$ and $taup$ in $taup(i)$.

if $m < n$,

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in $a(i+2:m, i)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $a(i, i+1:n)$; $tauq$ is stored in $tauq(i)$ and $taup$ in $taup(i)$.

The contents of a on exit are illustrated by the following examples with $nb = 2$:

$m=6, n=5 \ (m>n)$

$$\begin{bmatrix} 1 & 1 & u_1 & u_1 & u_1 \\ v_1 & 1 & 1 & u_2 & u_2 \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

$m=5, n=6 \ (m<n)$

$$\begin{bmatrix} 1 & u_1 & u_1 & u_1 & u_1 & u_1 \\ 1 & 1 & u_2 & u_2 & u_2 & u_2 \\ v_1 & 1 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix which is unchanged, v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

zlacn2

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

```
call slacn2( n, v, x, isgn, est, kase, isave )
call dlacn2( n, v, x, isgn, est, kase, isave )
call clacn2( n, v, x, est, kase, isave )
call zlacn2( n, v, x, est, kase, isave )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine estimates the 1-norm of a square, real or complex matrix A . Reverse communication is used for evaluating matrix-vector products.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 1$).
<i>v</i> , <i>x</i>	REAL for <i>slacn2</i> DOUBLE PRECISION for <i>dlacn2</i> COMPLEX for <i>clacn2</i> COMPLEX*16 for <i>zlacn2</i> . Arrays, DIMENSION (<i>n</i>) each. <i>v</i> is a workspace array. <i>x</i> is used as input after an intermediate return.
<i>isgn</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>), used with real flavors only.
<i>est</i>	REAL for <i>slacn2/clacn2</i> DOUBLE PRECISION for <i>dlacn2/zlacn2</i> On entry with <i>kase</i> set to 1 or 2, and <i>isave</i> (1) = 1, <i>est</i> must be unchanged from the previous call to the routine.
<i>kase</i>	INTEGER. On the initial call to the routine, <i>kase</i> must be set to 0.
<i>isave</i>	INTEGER. Array, DIMENSION (3). Contains variables from the previous call to the routine.

Output Parameters

<i>est</i>	An estimate (a lower bound) for $\text{norm}(A)$.
<i>kase</i>	On an intermediate return, <i>kase</i> is set to 1 or 2, indicating whether <i>x</i> is overwritten by $A*x$ or $A'*x$. On the final return, <i>kase</i> is set to 0.
<i>v</i>	On the final return, $v = A*w$, where $est = \text{norm}(v)/\text{norm}(w)$ (<i>w</i> is not returned).
<i>x</i>	On an intermediate return, <i>x</i> is overwritten by $A*x$, if <i>kase</i> = 1, $A'*x$, if <i>kase</i> = 2, (A' is the conjugate transpose of <i>A</i>), and the routine must be re-called with all the other parameters unchanged.
<i>isave</i>	This parameter is used to save variables between calls to the routine.

?lacon

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

```
call slacon( n, v, x, isgn, est, kase )
call dlacon( n, v, x, isgn, est, kase )
call clacon( n, v, x, est, kase )
call zlacon( n, v, x, est, kase )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine estimates the 1-norm of a square, real/complex matrix *A*. Reverse communication is used for evaluating matrix-vector products.

WARNING. The `?lacon` routine is not thread-safe. It is deprecated and retained for the backward compatibility only. Use the thread-safe `?lacn2` routine instead.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 1$).
<i>v</i> , <i>x</i>	REAL for <code>slacon</code> DOUBLE PRECISION for <code>dlacon</code> COMPLEX for <code>clacon</code> COMPLEX*16 for <code>zlacon</code> . Arrays, DIMENSION (<i>n</i>) each. <i>v</i> is a workspace array. <i>x</i> is used as input after an intermediate return.
<i>isgn</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>), used with real flavors only.

est REAL for slacon/clacon
DOUBLE PRECISION for dlacon/zlacon
An estimate that with *kase*=1 or 2 should be unchanged from the previous call to ?lacon.

kase INTEGER.
On the initial call to ?lacon, *kase* should be 0.

Output Parameters

est REAL for slacon/clacon
DOUBLE PRECISION for dlacon/zlacon
An estimate (a lower bound) for $\text{norm}(A)$.

kase On an intermediate return, *kase* will be 1 or 2, indicating whether *x* should be overwritten by $A*x$ or $A'*x$. On the final return from ?lacon, *kase* will again be 0.

v On the final return, $v = A*w$, where $est = \text{norm}(v)/\text{norm}(w)$ (*w* is not returned).

x On an intermediate return, *x* should be overwritten by $A*x$, if *kase* = 1,
 $A'*x$, if *kase* = 2,
(where for complex flavors A' is the conjugate transpose of *A*), and ?lacon must be re-called with all the other parameters unchanged.

?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call slacpy( uplo, m, n, a, lda, b, ldb )
call dlacpy( uplo, m, n, a, lda, b, ldb )
call clacpy( uplo, m, n, a, lda, b, ldb )
call zlacpy( uplo, m, n, a, lda, b, ldb )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine copies all or part of a two-dimensional matrix A to another matrix B .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies the part of the matrix A to be copied to B . If <i>uplo</i> = 'U', the upper triangular part of ; if <i>uplo</i> = 'L', the lower triangular part of A . Otherwise, all of the matrix A is copied.
<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a</i>	REAL for slacpy DOUBLE PRECISION for dlacpy COMPLEX for clacpy COMPLEX*16 for zlacpy. Array $a(lda, *)$, contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. If <i>uplo</i> = 'U', only the upper triangle or trapezoid is accessed; if <i>uplo</i> = 'L', only the lower triangle or trapezoid is accessed.
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of the output array b ; $ldb \geq \max(1, m)$.

Output Parameters

<i>b</i>	REAL for slacpy DOUBLE PRECISION for dlacpy COMPLEX for clacpy COMPLEX*16 for zlacpy. Array $b(ldb, *)$, contains the m -by- n matrix B . The second dimension of b must be at least $\max(1, n)$. On exit, $B = A$ in the locations specified by <i>uplo</i> .
----------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

?ladiv

*Performs complex division in real arithmetic,
avoiding unnecessary overflow.*

Syntax

```
call sladiv( a, b, c, d, p, q )
```

```
call dladiv( a, b, c, d, p, q )
```

```
res = cladiv( x, y )
```

```
res = zladiv( x, y )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routines `sladiv/dladiv` perform complex division in real arithmetic as

$$p + iq = \frac{a + ib}{c + id}$$

Complex functions `cladiv/zladiv` compute the result as

```
res = x/y,
```

where x and y are complex. The computation of x/y will not overflow on an intermediary step unless the results overflows.

Input Parameters

a, b, c, d

REAL for `sladiv`

DOUBLE PRECISION for `dladiv`

The scalars a, b, c , and d in the above expression (for real flavors only).

x, y

COMPLEX for `cladiv`

COMPLEX*16 for `zladiv`

The complex scalars x and y (for complex flavors only).

Output Parameters

p, q	REAL for sladiv DOUBLE PRECISION for dladiv The scalars p and q in the above expression (for real flavors only).
res	COMPLEX for cladiv DOUBLE COMPLEX for zladiv Contains the result of division x / y .

?lae2

Computes the eigenvalues of a 2-by-2 symmetric matrix.

Syntax

```
call slae2( a, b, c, rt1, rt2 )
call dlae2( a, b, c, rt1, rt2 )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routines `sla2/dlae2` compute the eigenvalues of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix}$$

On return, $rt1$ is the eigenvalue of larger absolute value, and $rt2$ is the eigenvalue of smaller absolute value.

Input Parameters

a, b, c	REAL for slae2 DOUBLE PRECISION for dlae2 The elements a , b , and c of the 2-by-2 matrix above.
-----------	--------------------------------------------------------------------------------------------------------------

Output Parameters

rt1, *rt2* REAL for `s1ae2`
 DOUBLE PRECISION for `d1ae2`
 The computed eigenvalues of larger and smaller absolute value, respectively.

Application Notes

rt1 is accurate to a few ulps barring over/underflow. *rt2* may be inaccurate if there is massive cancellation in the determinant $a*c-b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute *rt2* accurately in all cases.

Overflow is possible only if *rt1* is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds

underflow_threshold / `macheps`.

?laebz

Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz.

Syntax

```
call slaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d,
e, e2, nval, ab, c, mout, nab, work, iwork, info )
```

```
call dlaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d,
e, e2, nval, ab, c, mout, nab, work, iwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?laebz` contains the iteration loops which compute and use the function $n(w)$, which is the count of eigenvalues of a symmetric tridiagonal matrix T less than or equal to its argument w . It performs a choice of two types of loops:

ijob =1, followed by

ijob =2: It takes as input a list of intervals and returns a list of sufficiently small intervals whose union contains the same eigenvalues as the union of the original intervals. The input intervals are $(ab(j,1), ab(j,2)]$, $j=1, \dots, minp$. The output interval $(ab(j,1), ab(j,2)]$ will contain eigenvalues $nab(j,1)+1, \dots, nab(j,2)$, where $1 \leq j \leq mout$.

ijob =3: It performs a binary search in each input interval $(ab(j,1), ab(j,2)]$ for a point $w(j)$ such that $n(w(j))=nval(j)$, and uses $c(j)$ as the starting point of the search. If such a $w(j)$ is found, then on output $ab(j,1)=ab(j,2)=w$. If no such $w(j)$ is found, then on output $(ab(j,1), ab(j,2)]$ will be a small interval containing the point where $n(w)$ jumps through $nval(j)$, unless that point lies outside the initial interval.

Note that the intervals are in all cases half-open intervals, that is, of the form $(a, b]$, which includes b but not a .

To avoid underflow, the matrix should be scaled so that its largest element is no greater than $overflow^{1/2} * overflow^{1/4}$ in absolute value. To assure the most accurate computation of small eigenvalues, the matrix should be scaled to be not much smaller than that, either.

NOTE. In general, the arguments are not checked for unreasonable values.

Input Parameters

ijob INTEGER. Specifies what is to be done:
 = 1: Compute *nab* for the initial intervals.
 = 2: Perform bisection iteration to find eigenvalues of *T*.
 = 3: Perform bisection iteration to invert $n(w)$, i.e., to find a point which has a specified number of eigenvalues of *T* to its left. Other values will cause *?laebz* to return with *info*=-1.

nitmax INTEGER. The maximum number of "levels" of bisection to be performed, i.e., an interval of width *w* will not be made smaller than $2^{-nitmax} * w$. If not all intervals have converged after *nitmax* iterations, then *info* is set to the number of non-converged intervals.

<i>n</i>	INTEGER. The dimension <i>n</i> of the tridiagonal matrix <i>T</i> . It must be at least 1.
<i>mmax</i>	INTEGER. The maximum number of intervals. If more than <i>mmax</i> intervals are generated, then ?laebz will quit with <i>info</i> = <i>mmax</i> +1.
<i>minp</i>	INTEGER. The initial number of intervals. It may not be greater than <i>mmax</i> .
<i>nbmin</i>	INTEGER. The smallest number of intervals that should be processed using a vector loop. If zero, then only the scalar loop will be used.
<i>abstol</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. The minimum (absolute) width of an interval. When an interval is narrower than <i>abstol</i> , or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. This must be at least zero.
<i>reltol</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. The minimum relative width of an interval. When an interval is narrower than <i>abstol</i> , or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least <i>radix</i> * <i>machine epsilon</i> .
<i>pivmin</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. The minimum absolute value of a "pivot" in the Sturm sequence loop. This value must be at least ($\max e(j) ^2 safe_min $) and at least <i>safe_min</i> , where <i>safe_min</i> is at least the smallest number that can divide one without overflow.
<i>d</i> , <i>e</i> , <i>e2</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. Arrays, dimension (<i>n</i>) each. The array <i>d</i> contains the diagonal elements of the tridiagonal matrix <i>T</i> . The array <i>e</i> contains the off-diagonal elements of the tridiagonal matrix <i>T</i> in positions 1 through <i>n</i> -1. <i>e</i> (<i>n</i>) is arbitrary.

	<p>The array <code>e2</code> contains the squares of the off-diagonal elements of the tridiagonal matrix T. <code>e2(n)</code> is ignored.</p>
<code>nval</code>	<p>INTEGER. Array, dimension (<i>minp</i>). If <i>ijob</i>=1 or 2, not referenced. If <i>ijob</i>=3, the desired values of $n(w)$.</p>
<code>ab</code>	<p>REAL for <code>slaebz</code> DOUBLE PRECISION for <code>dlaebz</code>. Array, dimension (<i>mmax</i>,2) The endpoints of the intervals. <code>ab(j,1)</code> is $a(j)$, the left endpoint of the j-th interval, and <code>ab(j,2)</code> is $b(j)$, the right endpoint of the j-th interval.</p>
<code>c</code>	<p>REAL for <code>slaebz</code> DOUBLE PRECISION for <code>dlaebz</code>. Array, dimension (<i>mmax</i>) If <i>ijob</i>=1, ignored. If <i>ijob</i>=2, workspace. If <i>ijob</i>=3, then on input <code>c(j)</code> should be initialized to the first search point in the binary search.</p>
<code>nab</code>	<p>INTEGER. Array, dimension (<i>mmax</i>,2) If <i>ijob</i>=2, then on input, <code>nab(i,j)</code> should be set. It must satisfy the condition: $n(ab(i,1)) \leq nab(i,1) \leq nab(i,2) \leq n(ab(i,2)),$ which means that in interval i only eigenvalues $nab(i,1)+1, \dots, nab(i,2)$ are considered. Usually, $nab(i,j)=n(ab(i,j))$, from a previous call to <code>?laebz</code> with <i>ijob</i>=1. If <i>ijob</i>=3, normally, <code>nab</code> should be set to some distinctive value(s) before <code>?laebz</code> is called.</p>
<code>work</code>	<p>REAL for <code>slaebz</code> DOUBLE PRECISION for <code>dlaebz</code>. Workspace array, dimension (<i>mmax</i>).</p>
<code>iwork</code>	<p>INTEGER. Workspace array, dimension (<i>mmax</i>).</p>

Output Parameters

<i>nval</i>	The elements of <i>nval</i> will be reordered to correspond with the intervals in <i>ab</i> . Thus, <i>nval</i> (<i>j</i>) on output will not, in general be the same as <i>nval</i> (<i>j</i>) on input, but it will correspond with the interval (<i>ab</i> (<i>j</i> ,1), <i>ab</i> (<i>j</i> ,2)] on output.
<i>ab</i>	The input intervals will, in general, be modified, split, and reordered by the calculation.
<i>mout</i>	INTEGER. If <i>ijob</i> =1, the number of eigenvalues in the intervals. If <i>ijob</i> =2 or 3, the number of intervals output. If <i>ijob</i> =3, <i>mout</i> will equal <i>minp</i> .
<i>nab</i>	If <i>ijob</i> =1, then on output <i>nab</i> (<i>i</i> , <i>j</i>) will be set to $N(ab(i,j))$. If <i>ijob</i> =2, then on output, <i>nab</i> (<i>i</i> , <i>j</i>) will contain $\max(na(k), \min(nb(k), N(ab(i,j))))$, where <i>k</i> is the index of the input interval that the output interval (<i>ab</i> (<i>j</i> ,1), <i>ab</i> (<i>j</i> ,2)] came from, and <i>na</i> (<i>k</i>) and <i>nb</i> (<i>k</i>) are the input values of <i>nab</i> (<i>k</i> ,1) and <i>nab</i> (<i>k</i> ,2). If <i>ijob</i> =3, then on output, <i>nab</i> (<i>i</i> , <i>j</i>) contains $N(ab(i,j))$, unless $N(w) > nval(i)$ for all search points <i>w</i> , in which case <i>nab</i> (<i>i</i> ,1) will not be modified, i.e., the output value will be the same as the input value (modulo reorderings, see <i>nval</i> and <i>ab</i>), or unless $N(w) < nval(i)$ for all search points <i>w</i> , in which case <i>nab</i> (<i>i</i> ,2) will not be modified.
<i>info</i>	INTEGER. If <i>info</i> = 0 - all intervals converged If <i>info</i> = 1-- <i>mmax</i> - the last <i>info</i> interval did not converge. If <i>info</i> = <i>mmax</i> +1 - more than <i>mmax</i> intervals were generated

Application Notes

This routine is intended to be called only by other LAPACK routines, thus the interface is less user-friendly. It is intended for two purposes:

(a) finding eigenvalues. In this case, *?laebz* should have one or more initial intervals set up in *ab*, and *?laebz* should be called with *ijob*=1. This sets up *nab*, and also counts the eigenvalues. Intervals with no eigenvalues would usually be thrown out at this point. Also, if

not all the eigenvalues in an interval i are desired, $nab(i,1)$ can be increased or $nab(i,2)$ decreased. For example, set $nab(i,1)=nab(i,2)-1$ to get the largest eigenvalue. `?laebz` is then called with $ijob=2$ and $mmax$ no smaller than the value of $mout$ returned by the call with $ijob=1$. After this ($ijob=2$) call, eigenvalues $nab(i,1)+1$ through $nab(i,2)$ are approximately $ab(i,1)$ (or $ab(i,2)$) to the tolerance specified by $abstol$ and $reltol$.

(b) finding an interval $(a',b']$ containing eigenvalues $w(f),\dots,w(l)$. In this case, start with a Gershgorin interval (a,b) . Set up ab to contain 2 search intervals, both initially (a,b) . One $nval$ element should contain $f-1$ and the other should contain l , while c should contain a and b , respectively. $nab(i,1)$ should be -1 and $nab(i,2)$ should be $n+1$, to flag an error if the desired interval does not lie in (a,b) . `?laebz` is then called with $ijob=3$. On exit, if $w(f-1) < w(f)$, then one of the intervals `-- j --` will have $ab(j,1)=ab(j,2)$ and $nab(j,1)=nab(j,2)=f-1$, while if, to the specified tolerance, $w(f-k)=\dots=w(f+r)$, $k > 0$ and $r \geq 0$, then the interval will have $n(ab(j,1))=nab(j,1)=f-k$ and $n(ab(j,2))=nab(j,2)=f+r$. The cases $w(1) < w(1+1)$ and $w(l-r)=\dots=w(l+k)$ are handled similarly.

?laed0

Used by ?stedc. Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.

Syntax

```
call slaed0( icompr, qsize, n, d, e, q, ldq, qstore, ldqs, work, iwork, info
)
call dlaed0( icompr, qsize, n, d, e, q, ldq, qstore, ldqs, work, iwork, info
)
call claed0( qsize, n, d, e, q, ldq, qstore, ldqs, rwork, iwork, info )
call zlaed0( qsize, n, d, e, q, ldq, qstore, ldqs, rwork, iwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

Real flavors of this routine compute all eigenvalues and (optionally) corresponding eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Complex flavors `claed0/zlaed0` compute all eigenvalues of a symmetric tridiagonal matrix which is one diagonal block of those from reducing a dense or band Hermitian matrix and corresponding eigenvectors of the dense or band matrix.

Input Parameters

icompg INTEGER. Used with real flavors only.
 If *icompg* = 0, compute eigenvalues only.
 If *icompg* = 1, compute eigenvectors of original dense symmetric matrix also.
 On entry, the array *q* must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
 If *icompg* = 2, compute eigenvalues and eigenvectors of the tridiagonal matrix.

qsiz INTEGER.
 The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; *qsiz* ≥ *n* (for real flavors, *qsiz* ≥ *n* if *icompg* = 1).

n INTEGER. The dimension of the symmetric tridiagonal matrix (*n* ≥ 0).

d, *e*, *rwork* REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors. Arrays:
d(*) contains the main diagonal of the tridiagonal matrix. The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the off-diagonal elements of the tridiagonal matrix. The dimension of *e* must be at least $\max(1, n-1)$.
rwork(*) is a workspace array used in complex flavors only. The dimension of *rwork* must be at least $(1 + 3n + 2n \lg(n) + 3n^2)$, where $\lg(n)$ = smallest integer *k* such that $2^k \geq n$.

q, *qstore* REAL for slaed0
 DOUBLE PRECISION for dlaed0
 COMPLEX for claed0
 COMPLEX*16 for zlaed0.
 Arrays: *q*(*ldq*, *), *qstore*(*ldqs*, *). The second dimension of these arrays must be at least $\max(1, n)$.
 For real flavors:

If $icompeq = 0$, array q is not referenced.

If $icompeq = 1$, on entry, q is a subset of the columns of the orthogonal matrix used to reduce the full matrix to tridiagonal form corresponding to the subset of the full matrix which is being decomposed at this time.

If $icompeq = 2$, on entry, q will be the identity matrix. The array $qstore$ is a workspace array referenced only when $icompeq = 1$. Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

For complex flavors:

On entry, q must contain an $qsiz$ -by- n matrix whose columns are unitarily orthonormal. It is a part of the unitary matrix that reduces the full dense Hermitian matrix to a (reducible) symmetric tridiagonal matrix. The array $qstore$ is a workspace array used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

ldq	INTEGER. The first dimension of the array q ; $ldq \geq \max(1, n)$.
$ldqs$	INTEGER. The first dimension of the array $qstore$; $ldqs \geq \max(1, n)$.
$work$	REAL for slaed0 DOUBLE PRECISION for dlaed0. Workspace array, used in real flavors only. If $icompeq = 0$ or 1 , the dimension of $work$ must be at least $(1 + 3n + 2n \lg(n) + 2n^2)$, where $\lg(n) =$ smallest integer k such that $2^k \geq n$. If $icompeq = 2$, the dimension of $work$ must be at least $(4n + n^2)$.
$iwork$	INTEGER. Workspace array. For real flavors, if $icompeq = 0$ or 1 , and for complex flavors, the dimension of $iwork$ must be at least $(6 + 6n + 5n \lg(n))$. For real flavors, if $icompeq = 2$, the dimension of $iwork$ must be at least $(3 + 5n)$.

Output Parameters

<i>d</i>	On exit, contains eigenvalues in ascending order.
<i>e</i>	On exit, the array is destroyed.
<i>q</i>	If <i>icompg</i> = 2, on exit, <i>q</i> contains the eigenvectors of the tridiagonal matrix.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> > 0, the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>i</i> /(<i>n</i> +1) through mod(<i>i</i> , <i>n</i> +1).

?laed1

Used by sstedc/dstedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.

Syntax

```
call slaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
call dlaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?laed1 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and eigenvectors of a tridiagonal matrix. ?laed7 handles the case in which eigenvalues only or eigenvalues and eigenvectors of a full symmetric matrix (which was reduced to tridiagonal form) are desired.

$$T = Q(in) * (D(in) + rho * Z * Z') * Q'(in) = Q(out) * D(out) * Q'(out)$$

where $Z = Q'u$, u is a vector of length n with ones in the *cutpnt* and (*cutpnt*+1)-th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine [?1aed2](#).

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine [?1aed4](#) (as called by [?1aed3](#)). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>d, q, work</i>	REAL for slaed1 DOUBLE PRECISION for dlaed1 . Arrays: <i>d</i> (*) contains the eigenvalues of the rank-1-perturbed matrix. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>q</i> (<i>ldq</i> , *) contains the eigenvectors of the rank-1-perturbed matrix. The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $(4n+n^2)$.
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). On entry, the permutation which separately sorts the two subproblems in <i>d</i> into ascending order.
<i>rho</i>	REAL for slaed1 DOUBLE PRECISION for dlaed1 . The subdiagonal entry used to create the rank-1 modification. This parameter can be modified by ?1aed2 , where it is input/output.
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq cutpnt \leq n/2$.

iwork INTEGER.
Workspace array, dimension $(4n)$.

Output Parameters

d On exit, contains the eigenvalues of the repaired matrix.

q On exit, *q* contains the eigenvectors of the repaired tridiagonal matrix.

indxq On exit, contains the permutation which will reintegrate the subproblems back into sorted order, that is, $d(\text{indxq}(i) = 1, n))$ will be in ascending order.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value. If *info* = 1, an eigenvalue did not converge.

?laed2

Used by sstedc/dstedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.

Syntax

```
call slaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc,
            indxp, coltyp, info )
```

```
call dlaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc,
            indxp, coltyp, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?laed2 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny entry in the *z* vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Input Parameters

<i>k</i>	INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation ($0 \leq k \leq n$).
<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>n1</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.
<i>d, q, z</i>	REAL for slaed2 DOUBLE PRECISION for dlaed2. Arrays: <i>d</i> (*) contains the eigenvalues of the two submatrices to be combined. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>q</i> (ldq, *) contains the eigenvectors of the two submatrices in the two square blocks with corners at (1,1), (n1,n1) and (n1+1,n1+1), (n,n). The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>z</i> (*) contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). On entry, the permutation which separately sorts the two subproblems in <i>d</i> into ascending order. Note that elements in the second half of this permutation must first have <i>n1</i> added to their values.
<i>rho</i>	REAL for slaed2 DOUBLE PRECISION for dlaed2. On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined.
<i>indx, indxp</i>	INTEGER. Workspace arrays, dimension (<i>n</i>) each. Array <i>indx</i> contains the permutation used to sort the contents of <i>d</i> into ascending order.

Array *indxp* contains the permutation used to place deflated values of *d* at the end of the array.

indxp(1:*k*) points to the nondeflated *d*-values and
indxp(*k*+1:*n*) points to the deflated eigenvalues.

coltyp

INTEGER.

Workspace array, dimension (*n*).

During execution, a label which will indicate which of the following types a column in the *q2* matrix is:

- 1 : non-zero in the upper half only;
- 2 : dense;
- 3 : non-zero in the lower half only;
- 4 : deflated.

Output Parameters

d

On exit, *d* contains the trailing (*n-k*) updated eigenvalues (those which were deflated) sorted into increasing order.

q

On exit, *q* contains the trailing (*n-k*) updated eigenvectors (those which were deflated) in its last *n-k* columns.

z

On exit, *z* content is destroyed by the updating process.

indxq

Destroyed on exit.

rho

On exit, *rho* has been modified to the value required by ?laed3.

dlamda, *w*, *q2*

REAL for slaed2

DOUBLE PRECISION for dlaed2.

Arrays: *dlamda*(*n*), *w*(*n*), *q2*(*n1*²+(*n-n1*)²).

The array *dlamda* contains a copy of the first *k* eigenvalues which is used by ?laed3 to form the secular equation.

The array *w* contains the first *k* values of the final deflation-altered *z*-vector which is passed to ?laed3.

The array *q2* contains a copy of the first *k* eigenvectors which is used by ?laed3 in a matrix multiply (sgemm/dgemm) to solve for the new eigenvectors.

indx

INTEGER. Array, dimension (*n*).

The permutation used to arrange the columns of the deflated q matrix into three groups: the first group contains non-zero elements only at and above $n1$, the second contains non-zero elements only below $n1$, and the third is dense.

coltyp On exit, *coltyp*(i) is the number of columns of type i , for $i=1$ to 4 only (see the definition of types in the description of *coltyp* in *Input Parameters*).

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = $-i$, the i -th parameter had an illegal value.

?laed3

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.

Syntax

```
call slaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
call dlaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?laed3 finds the roots of the secular equation, as defined by the values in d , w , and ρ , between 1 and k .

It makes the appropriate calls to ?laed4 and then updates the eigenvectors by multiplying the matrix of eigenvectors of the pair of eigensystems being combined by the matrix of eigenvectors of the k -by- k system which is solved here.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but none are known.

Input Parameters

<i>k</i>	INTEGER. The number of terms in the rational function to be solved by ?laed4 ($k \geq 0$).
<i>n</i>	INTEGER. The number of rows and columns in the <i>q</i> matrix. $n \geq k$ (deflation may result in $n > k$).
<i>n1</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.
<i>q</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3. Array <i>q</i> (<i>ldq</i> , *). The second dimension of <i>q</i> must be at least $\max(1, n)$. Initially, the first <i>k</i> columns of this array are used as workspace.
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>rho</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3. The value of the parameter in the rank one update equation. $\rho \geq 0$ required.
<i>dlambda</i> , <i>q2</i> , <i>w</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3. Arrays: <i>dlambda</i> (<i>k</i>), <i>q2</i> (<i>ldq2</i> , *), <i>w</i> (<i>k</i>). The first <i>k</i> elements of the array <i>dlambda</i> contain the old roots of the deflated updating problem. These are the poles of the secular equation. The first <i>k</i> columns of the array <i>q2</i> contain the non-deflated eigenvectors for the split problem. The second dimension of <i>q2</i> must be at least $\max(1, n)$. The first <i>k</i> elements of the array <i>w</i> contain the components of the deflation-adjusted updating vector.
<i>indx</i>	INTEGER. Array, dimension (<i>n</i>). The permutation used to arrange the columns of the deflated <i>q</i> matrix into three groups (see ?laed2).

The rows of the eigenvectors found by `?laed4` must be likewise permuted before the matrix multiply can take place.

ctot INTEGER. Array, dimension (4).
A count of the total number of the various types of columns in *q*, as described in *indx*. The fourth column type is any column which has been deflated.

s REAL for `slaed3`
DOUBLE PRECISION for `dlaed3`.
Workspace array, dimension $(n1+1)*k$.
Will contain the eigenvectors of the repaired matrix which will be multiplied by the previously accumulated eigenvectors to update the system.

Output Parameters

d REAL for `slaed3`
DOUBLE PRECISION for `dlaed3`.
Array, dimension at least $\max(1, n)$.
d(i) contains the updated eigenvalues for $1 \leq i \leq k$.

q On exit, the columns 1 to *k* of *q* contain the updated eigenvectors.

dlamda May be changed on output by having lowest order bit set to zero on Cray X-MP, Cray Y-MP, Cray-2, or Cray C-90, as described above.

w Destroyed on exit.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = 1, an eigenvalue did not converge.

slaed4

Used by sstedc/dstedc. Finds a single root of the secular equation.

Syntax

```
call slaed4( n, i, d, z, delta, rho, dlam, info )
```

```
call dlaed4( n, i, d, z, delta, rho, dlam, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

This routine computes the i -th updated eigenvalue of a symmetric rank-one modification to a diagonal matrix whose elements are given in the array d , and that

$$D(i) < D(j) \text{ for } i < j$$

and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$$\text{diag}(D) + \rho * Z * \text{transpose}(Z).$$

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

n	INTEGER. The length of all arrays.
i	INTEGER. The index of the eigenvalue to be computed; $1 \leq i \leq n$.
d, z	REAL for <code>slaed4</code> DOUBLE PRECISION for <code>dlaed4</code> Arrays, dimension (n) each. The array d contains the original eigenvalues. It is assumed that they are in order, $d(i) < d(j)$ for $i < j$. The array z contains the components of the updating vector Z .

rho REAL for slaed4
DOUBLE PRECISION for dlaed4
The scalar in the symmetric updating formula.

Output Parameters

delta REAL for slaed4
DOUBLE PRECISION for dlaed4
Array, dimension (*n*).
If $n \neq 1$, *delta* contains $(d(j) - \lambda_i)$ in its *j*-th component. If $n = 1$, then $\text{delta}(1) = 1$. The vector *delta* contains the information necessary to construct the eigenvectors.

diam REAL for slaed4
DOUBLE PRECISION for dlaed4
The computed λ_i , the *i*-th updated eigenvalue.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = 1, the updating process failed.

?laed5

Used by sstedc/dstedc. Solves the 2-by-2 secular equation.

Syntax

```
call slaed5( i, d, z, delta, rho, diam )
call dlaed5( i, d, z, delta, rho, diam )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the *i*-th eigenvalue of a symmetric rank-one modification of a 2-by-2 diagonal matrix

$\text{diag}(D) + \rho * Z * \text{transpose}(Z)$.

The diagonal elements in the array *D* are assumed to satisfy

$D(i) < D(j)$ for $i < j$.

We also assume $\rho > 0$ and that the Euclidean norm of the vector z is one.

Input Parameters

i INTEGER. The index of the eigenvalue to be computed;
 $1 \leq i \leq 2$.

d, *z* REAL for slaed5
 DOUBLE PRECISION for dlaed5
 Arrays, dimension (2) each. The array *d* contains the original eigenvalues. It is assumed that $d(1) < d(2)$.
 The array *z* contains the components of the updating vector.

rho REAL for slaed5
 DOUBLE PRECISION for dlaed5
 The scalar in the symmetric updating formula.

Output Parameters

delta REAL for slaed5
 DOUBLE PRECISION for dlaed5
 Array, dimension (2).
 The vector *delta* contains the information necessary to construct the eigenvectors.

diam REAL for slaed5
 DOUBLE PRECISION for dlaed5
 The computed λ_i , the *i*-th updated eigenvalue.

slaed6

Used by sstedc/dstedc. Computes one Newton step in solution of the secular equation.

Syntax

```
call slaed6( kniter, orgati, rho, d, z, finit, tau, info )
call dlaed6( kniter, orgati, rho, d, z, finit, tau, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the positive or negative root (closest to the origin) of

$$f(x) = \rho + \frac{z(1)}{d(1) - x} + \frac{z(2)}{d(2) - x} + \frac{z(3)}{d(3) - x}$$

It is assumed that if `orgati = .TRUE.` the root is between $d(2)$ and $d(3)$; otherwise it is between $d(1)$ and $d(2)$. This routine is called by `?laed4` when necessary. In most cases, the root sought is the smallest in magnitude, though it might not be in some extremely rare situations.

Input Parameters

<i>kniter</i>	INTEGER. Refer to <code>?laed4</code> for its significance.
<i>orgati</i>	LOGICAL. If <code>orgati = .TRUE.</code> , the needed root is between $d(2)$ and $d(3)$; otherwise it is between $d(1)$ and $d(2)$. See <code>?laed4</code> for further details.
<i>rho</i>	REAL for <code>slaed6</code> DOUBLE PRECISION for <code>dlaed6</code> Refer to the equation for $f(x)$ above.
<i>d, z</i>	REAL for <code>slaed6</code> DOUBLE PRECISION for <code>dlaed6</code> Arrays, dimension (3) each. The array d satisfies $d(1) < d(2) < d(3)$. Each of the elements in the array z must be positive.
<i>finit</i>	REAL for <code>slaed6</code> DOUBLE PRECISION for <code>dlaed6</code> The value of $f(x)$ at 0. It is more accurate than the one evaluated inside this routine (if someone wants to do so).

Output Parameters

<i>tau</i>	REAL for <code>slaed6</code>
------------	------------------------------

`info` DOUBLE PRECISION for `dlaed6`
 The root of the equation for $f(x)$.
 INTEGER.
 If `info` = 0, the execution is successful.
 If `info` = 1, failure to converge.

?laed7

Used by ?stedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.

Syntax

```

call slaed7( icompg, n, qsiz, tlvl, curlvl, curpbm, d, q, ldq, indxq, rho,
cutpnt, qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info
)

call dlaed7( icompg, n, qsiz, tlvl, curlvl, curpbm, d, q, ldq, indxq, rho,
cutpnt, qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info
)

call claed7( n, cutpnt, qsiz, tlvl, curlvl, curpbm, d, q, ldq, rho, indxq,
qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, rwork, iwork, info
)

call zlaed7( n, cutpnt, qsiz, tlvl, curlvl, curpbm, d, q, ldq, rho, indxq,
qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, rwork, iwork, info
)

```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?laed7 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense symmetric/Hermitian matrix that has been reduced to tridiagonal form. For real flavors, `slaed1/dlaed1` handles the case in which all eigenvalues and eigenvectors of a symmetric tridiagonal matrix are desired.

$$T = Q(in) * (D(in) + rho * Z * Z') * Q'(in) = Q(out) * D(out) * Q'(out)$$

where $Z = Q' * u$, u is a vector of length n with ones in the $cutpnt$ and $(cutpnt + 1)$ -th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `slaed8/dlaed8` (for real flavors) or by the routine `slaed2/dlaed2` (for complex flavors).

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine `?laed4` (as called by `?laed9` or `?laed3`). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

<i>icompg</i>	INTEGER. Used with real flavors only. If <i>icompg</i> = 0, compute eigenvalues only. If <i>icompg</i> = 1, compute eigenvectors of original dense symmetric matrix also. On entry, the array <i>q</i> must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq cutpnt \leq n$.
<i>qsiz</i>	INTEGER. The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <i>icompg</i> = 1).
<i>tlvls</i>	INTEGER. The total number of merging levels in the overall divide and conquer tree.
<i>curlvl</i>	INTEGER. The current level in the overall merge routine, $0 \leq curlvl \leq tlvls$.

<i>curpbm</i>	INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).
<i>d</i>	REAL for slaed7/claed7 DOUBLE PRECISION for dlaed7/zlaed7. Array, dimension at least $\max(1, n)$. Array <i>d</i> (*) contains the eigenvalues of the rank-1-perturbed matrix.
<i>q, work</i>	REAL for slaed7 DOUBLE PRECISION for dlaed7 COMPLEX for claed7 COMPLEX*16 for zlaed7. Arrays: <i>q</i> (<i>ldq</i> , *) contains the eigenvectors of the rank-1-perturbed matrix. The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $(3n+qsize*n)$ for real flavors and at least $(qsize*n)$ for complex flavors.
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). Contains the permutation that separately sorts the two sub-problems in <i>d</i> into ascending order.
<i>rho</i>	REAL for slaed7 /claed7 DOUBLE PRECISION for dlaed7/zlaed7. The subdiagonal element used to create the rank-1 modification.
<i>qstore</i>	REAL for slaed7/claed7 DOUBLE PRECISION for dlaed7/zlaed7. Array, dimension (n^2+1) . Serves also as output parameter. Stores eigenvectors of submatrices encountered during divide and conquer, packed together. <i>qptr</i> points to beginning of the submatrices.

<i>qptr</i>	INTEGER. Array, dimension $(n+2)$. Serves also as output parameter. List of indices pointing to beginning of submatrices stored in <i>qstore</i> . The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.
<i>prmptr, perm, givptr</i>	INTEGER. Arrays, dimension $(n \lg n)$ each. The array <i>prmptr</i> (*) contains a list of pointers which indicate where in <i>perm</i> a level's permutation is stored. <i>prmptr</i> (i+1) - <i>prmptr</i> (i) indicates the size of the permutation and also the size of the full, non-deflated problem. The array <i>perm</i> (*) contains the permutations (from deflation and sorting) to be applied to each eigenblock. This parameter can be modified by ?laed8, where it is output. The array <i>givptr</i> (*) contains a list of pointers which indicate where in <i>givcol</i> a level's Givens rotations are stored. <i>givptr</i> (i+1) - <i>givptr</i> (i) indicates the number of Givens rotations.
<i>givcol</i>	INTEGER. Array, dimension $(2, n \lg n)$. Each pair of numbers indicates a pair of columns to take place in a Givens rotation.
<i>givnum</i>	REAL for slaed7/claed7 DOUBLE PRECISION for dlaed7/zlaed7. Array, dimension $(2, n \lg n)$. Each number indicates the <i>s</i> value to be used in the corresponding Givens rotation.
<i>iwork</i>	INTEGER. Workspace array, dimension $(4n)$.
<i>rwork</i>	REAL for claed7 DOUBLE PRECISION for zlaed7. Workspace array, dimension $(3n+2qsz*n)$. Used in complex flavors only.

Output Parameters

<i>d</i>	On exit, contains the eigenvalues of the repaired matrix.
<i>q</i>	On exit, <i>q</i> contains the eigenvectors of the repaired tridiagonal matrix.

<i>indxq</i>	<p>INTEGER. Array, dimension (<i>n</i>).</p> <p>Contains the permutation that reintegrates the subproblems back into a sorted order, that is, $d(\text{indxq}(i = 1, n))$ will be in the ascending order.</p>
<i>rho</i>	<p>This parameter can be modified by <code>?laed8</code>, where it is input/output.</p>
<i>prmptr, perm, givptr</i>	<p>INTEGER. Arrays, dimension (<i>n</i> <i>lgn</i>) each.</p> <p>The array <i>prmptr</i> contains an updated list of pointers.</p> <p>The array <i>perm</i> contains an updated permutation.</p> <p>The array <i>givptr</i> contains an updated list of pointers.</p>
<i>givcol</i>	<p>This parameter can be modified by <code>?laed8</code>, where it is output.</p>
<i>givnum</i>	<p>This parameter can be modified by <code>?laed8</code>, where it is output.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p> <p>If <i>info</i> = 1, an eigenvalue did not converge.</p>

?laed8

Used by ?stedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.

Syntax

```
call slaed8( icompg, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda,
q2, ldq2, w, perm, givptr, givcol, givnum, indxp, indx, info )

call dlaed8( icompg, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda,
q2, ldq2, w, perm, givptr, givcol, givnum, indxp, indx, info )

call claed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indxp,
indx, indxq, perm, givptr, givcol, givnum, info )

call zlaed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indxp,
indx, indxq, perm, givptr, givcol, givnum, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

<i>qsiz</i>	<p>INTEGER.</p> <p>The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <i>icompg</i> = 1).</p>
<i>d, z</i>	<p>REAL for slaed8/claed8</p> <p>DOUBLE PRECISION for dlaed8/zlaed8.</p> <p>Arrays, dimension at least $\max(1, n)$ each. The array <i>d</i>(*) contains the eigenvalues of the two submatrices to be combined.</p> <p>On entry, <i>z</i>(*) contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). The contents of <i>z</i> are destroyed by the updating process.</p>
<i>q</i>	<p>REAL for slaed8</p> <p>DOUBLE PRECISION for dlaed8</p> <p>COMPLEX for claed8</p>

COMPLEX*16 for `zlaed8`.

Array

$q(ldq, *)$. The second dimension of q must be at least $\max(1, n)$. On entry, q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems. For real flavors, If $icompq = 0$, q is not referenced.

ldq	INTEGER. The first dimension of the array q ; $ldq \geq \max(1, n)$.
$ldq2$	INTEGER. The first dimension of the output array $q2$; $ldq2 \geq \max(1, n)$.
$indxq$	INTEGER. Array, dimension (n). The permutation that separately sorts the two sub-problems in d into ascending order. Note that elements in the second half of this permutation must first have $cutpnt$ added to their values in order to be accurate.
ρ	REAL for <code>slaed8/claed8</code> DOUBLE PRECISION for <code>dlaed8/zlaed8</code> . On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined.

Output Parameters

k	INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation.
d	On exit, contains the trailing ($n-k$) updated eigenvalues (those which were deflated) sorted into increasing order.
z	On exit, the updating process destroys the contents of z .
q	On exit, q contains the trailing ($n-k$) updated eigenvectors (those which were deflated) in its last ($n-k$) columns.
$indxq$	INTEGER. Array, dimension (n). The permutation of merged eigenvalues set.
ρ	On exit, ρ has been modified to the value required by ?laed3.
$d\lambda, w$	REAL for <code>slaed8/claed8</code>

	<p>DOUBLE PRECISION for dlaed8/zlaed8.</p> <p>Arrays, dimension (n) each. The array <i>dlaλda</i>(*) contains a copy of the first k eigenvalues which will be used by ?laed3 to form the secular equation.</p> <p>The array <i>w</i>(*) will hold the first k values of the final deflation-altered <i>z</i>-vector and will be passed to ?laed3.</p>
<i>q2</i>	<p>REAL for slaed8</p> <p>DOUBLE PRECISION for dlaed8</p> <p>COMPLEX for claed8</p> <p>COMPLEX*16 for zlaed8.</p> <p>Array</p> <p><i>q2</i>(<i>ldq2</i>, *). The second dimension of <i>q2</i> must be at least $\max(1, n)$.</p> <p>Contains a copy of the first k eigenvectors which will be used by slaed7/dlaed7 in a matrix multiply (<i>sgemm</i>/<i>dgemm</i>) to update the new eigenvectors. For real flavors, If <i>icompg</i> = 0, <i>q2</i> is not referenced.</p>
<i>indxp, indx</i>	<p>INTEGER. Workspace arrays, dimension (n) each.</p> <p>The array <i>indxp</i>(*) will contain the permutation used to place deflated values of <i>d</i> at the end of the array. On output, <i>indxp</i>(1:k) points to the nondeflated <i>d</i>-values and <i>indxp</i>($k+1:n$) points to the deflated eigenvalues.</p> <p>The array <i>indx</i>(*) will contain the permutation used to sort the contents of <i>d</i> into ascending order.</p>
<i>perm</i>	<p>INTEGER. Array, dimension (n).</p> <p>Contains the permutations (from deflation and sorting) to be applied to each eigenblock.</p>
<i>givptr</i>	<p>INTEGER. Contains the number of Givens rotations which took place in this subproblem.</p>
<i>givcol</i>	<p>INTEGER. Array, dimension (2, n).</p> <p>Each pair of numbers indicates a pair of columns to take place in a Givens rotation.</p>
<i>givnum</i>	<p>REAL for slaed8/claed8</p> <p>DOUBLE PRECISION for dlaed8/zlaed8.</p> <p>Array, dimension (2, n).</p> <p>Each number indicates the <i>s</i> value to be used in the corresponding Givens rotation.</p>

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

slaed9

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.

Syntax

```
call slaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
call dlaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine finds the roots of the secular equation, as defined by the values in *d*, *z*, and *rho*, between *kstart* and *kstop*. It makes the appropriate calls to `slaed4/dlaed4` and then stores the new matrix of eigenvectors for use in calculating the next level of *z* vectors.

Input Parameters

k INTEGER. The number of terms in the rational function to be solved by `slaed4/dlaed4` ($k \geq 0$).

kstart, kstop INTEGER. The updated eigenvalues $\lambda(i)$, $kstart \leq i \leq kstop$ are to be computed.
 $1 \leq kstart \leq kstop \leq k$.

n INTEGER. The number of rows and columns in the *Q* matrix.
 $n \geq k$ (deflation may result in $n > k$).

q REAL for `slaed9`
 DOUBLE PRECISION for `dlaed9`.
 Workspace array, dimension (*ldq*, *).
 The second dimension of *q* must be at least $\max(1, n)$.

<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>rho</i>	REAL for slaed9 DOUBLE PRECISION for dlaed9 The value of the parameter in the rank one update equation. $\rho \geq 0$ required.
<i>dlamda, w</i>	REAL for slaed9 DOUBLE PRECISION for dlaed9 Arrays, dimension (<i>k</i>) each. The first <i>k</i> elements of the array <i>dlamda</i> (*) contain the old roots of the deflated updating problem. These are the poles of the secular equation. The first <i>k</i> elements of the array <i>w</i> (*) contain the components of the deflation-adjusted updating vector.
<i>lds</i>	INTEGER. The first dimension of the output array <i>s</i> ; $lds \geq \max(1, k)$.

Output Parameters

<i>d</i>	REAL for slaed9 DOUBLE PRECISION for dlaed9 Array, dimension (<i>n</i>). Elements in <i>d</i> (<i>i</i>) are not referenced for $1 \leq i < kstart$ or $kstop < i \leq n$.
<i>s</i>	REAL for slaed9 DOUBLE PRECISION for dlaed9. Array, dimension (<i>lds</i> , *) . The second dimension of <i>s</i> must be at least $\max(1, k)$. Will contain the eigenvectors of the repaired matrix which will be stored for subsequent <i>z</i> vector calculation and multiplied by the previously accumulated eigenvectors to update the system.
<i>dlamda</i>	On exit, the value is modified to make sure all <i>dlamda</i> (<i>i</i>) – <i>dlamda</i> (<i>j</i>) can be computed with high relative accuracy, barring overflow and underflow.
<i>w</i>	Destroyed on exit.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value. If $info = 1$, the eigenvalue did not converge.

?laeda

Used by ?stedc. Computes the Z vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.

Syntax

```
call slaeda( n, tlvl, curlvl, curpbm, prmptr, perm, givptr, givcol, givnum,
q, qptr, z, ztemp, info )
call dlaeda( n, tlvl, curlvl, curpbm, prmptr, perm, givptr, givcol, givnum,
q, qptr, z, ztemp, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?laeda computes the z vector corresponding to the merge step in the $curlvl$ -th step of the merge process with $tlvl$ steps for the $curpbm$ -th problem.

Input Parameters

n	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
$tlvl$	INTEGER. The total number of merging levels in the overall divide and conquer tree.
$curlvl$	INTEGER. The current level in the overall merge routine, $0 \leq curlvl \leq tlvl$.
$curpbm$	INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).
$prmptr, perm, givptr$	INTEGER. Arrays, dimension $(n \lg n)$ each.

The array *prmptr*(*) contains a list of pointers which indicate where in *perm* a level's permutation is stored. *prmptr*(*i*+1) - *prmptr*(*i*) indicates the size of the permutation and also the size of the full, non-deflated problem.

The array *perm*(*) contains the permutations (from deflation and sorting) to be applied to each eigenblock.

The array *givptr*(*) contains a list of pointers which indicate where in *givcol* a level's Givens rotations are stored.

givptr(*i*+1) - *givptr*(*i*) indicates the number of Givens rotations.

givcol

INTEGER. Array, dimension (2, *n* lg *n*).

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

givnum

REAL for slaeda

DOUBLE PRECISION for dlaeda.

Array, dimension (2, *n* lg *n*).

Each number indicates the *s* value to be used in the corresponding Givens rotation.

q

REAL for slaeda

DOUBLE PRECISION for dlaeda.

Array, dimension (*n*²).

Contains the square eigenblocks from previous levels, the starting positions for blocks are given by *qptr*.

qptr

INTEGER. Array, dimension (*n*+2). Contains a list of pointers which indicate where in *q* an eigenblock is stored. *sqrt*(*qptr*(*i*+1) - *qptr*(*i*)) indicates the size of the block.

ztemp

REAL for slaeda

DOUBLE PRECISION for dlaeda.

Workspace array, dimension (*n*).

Output Parameters

z

REAL for slaeda

DOUBLE PRECISION for dlaeda.

Array, dimension (*n*). Contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

?laein

Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.

Syntax

```
call slaein( rightv, noint, n, h, ldh, wr, wi, vr, vi, b, ldb, work, eps3,
smlnum, bignum, info )

call dlaein( rightv, noint, n, h, ldh, wr, wi, vr, vi, b, ldb, work, eps3,
smlnum, bignum, info )

call claein( rightv, noint, n, h, ldh, w, v, b, ldb, rwork, eps3, smlnum,
info )

call zlaein( rightv, noint, n, h, ldh, w, v, b, ldb, rwork, eps3, smlnum,
info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?laein uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue (wr, wi) of a real upper Hessenberg matrix H (for real flavors slaein/dlaein) or to the eigenvalue w of a complex upper Hessenberg matrix H (for complex flavors claein/zlaein).

Input Parameters

rightv LOGICAL.
 If *rightv* = .TRUE., compute right eigenvector;
 if *rightv* = .FALSE., compute left eigenvector.

noint LOGICAL.
 If *noint* = .TRUE., no initial vector is supplied in (vr, vi)
 or in v (for complex flavors);

	if <i>noinit</i> = .FALSE., initial vector is supplied in (<i>vr</i> , <i>vi</i>) or in <i>v</i> (for complex flavors).
<i>n</i>	INTEGER. The order of the matrix <i>H</i> ($n \geq 0$).
<i>h</i>	REAL for <i>slaein</i> DOUBLE PRECISION for <i>dlaein</i> COMPLEX for <i>claein</i> COMPLEX*16 for <i>zlaein</i> . Array <i>h</i> (<i>ldh</i> , *). The second dimension of <i>h</i> must be at least $\max(1, n)$. Contains the upper Hessenberg matrix <i>H</i> .
<i>ldh</i>	INTEGER. The first dimension of the array <i>h</i> ; $ldh \geq \max(1, n)$.
<i>wr</i> , <i>wi</i>	REAL for <i>slaein</i> DOUBLE PRECISION for <i>dlaein</i> . The real and imaginary parts of the eigenvalue of <i>H</i> whose corresponding right or left eigenvector is to be computed (for real flavors of the routine).
<i>w</i>	COMPLEX for <i>claein</i> COMPLEX*16 for <i>zlaein</i> . The eigenvalue of <i>H</i> whose corresponding right or left eigenvector is to be computed (for complex flavors of the routine).
<i>vr</i> , <i>vi</i>	REAL for <i>slaein</i> DOUBLE PRECISION for <i>dlaein</i> . Arrays, dimension (<i>n</i>) each. Used for real flavors only. On entry, if <i>noinit</i> = .FALSE. and <i>wi</i> = 0.0, <i>vr</i> must contain a real starting vector for inverse iteration using the real eigenvalue <i>wr</i> ; if <i>noinit</i> = .FALSE. and <i>wi</i> \neq 0.0, <i>vr</i> and <i>vi</i> must contain the real and imaginary parts of a complex starting vector for inverse iteration using the complex eigenvalue (<i>wr</i> , <i>wi</i>); otherwise <i>vr</i> and <i>vi</i> need not be set.
<i>v</i>	COMPLEX for <i>claein</i> COMPLEX*16 for <i>zlaein</i> .

	<p>Array, dimension (n). Used for complex flavors only. On entry, if <i>noinit</i> = <i>.FALSE.</i>, <i>v</i> must contain a starting vector for inverse iteration; otherwise <i>v</i> need not be set.</p>
<i>b</i>	<p>REAL for <i>slaein</i> DOUBLE PRECISION for <i>dlaein</i> COMPLEX for <i>claein</i> COMPLEX*16 for <i>zlaein</i>. Workspace array <i>b</i>(<i>ldb</i>, *). The second dimension of <i>b</i> must be at least $\max(1, n)$.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of the array <i>b</i>; $ldb \geq n+1$ for real flavors; $ldb \geq \max(1, n)$ for complex flavors.</p>
<i>work</i>	<p>REAL for <i>slaein</i> DOUBLE PRECISION for <i>dlaein</i>. Workspace array, dimension (n). Used for real flavors only.</p>
<i>rwork</i>	<p>REAL for <i>claein</i> DOUBLE PRECISION for <i>zlaein</i>. Workspace array, dimension (n). Used for complex flavors only.</p>
<i>eps3</i> , <i>smlnum</i>	<p>REAL for <i>slaein/claein</i> DOUBLE PRECISION for <i>dlaein/zlaein</i>. <i>eps3</i> is a small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots. <i>smlnum</i> is a machine-dependent value close to underflow threshold.</p>
<i>bignum</i>	<p>REAL for <i>slaein</i> DOUBLE PRECISION for <i>dlaein</i>. <i>bignum</i> is a machine-dependent value close to overflow threshold. Used for real flavors only.</p>

Output Parameters

<i>vr</i> , <i>vi</i>	<p>On exit, if $w_i = 0.0$ (real eigenvalue), <i>vr</i> contains the computed real eigenvector; if $w_i \neq 0.0$ (complex eigenvalue), <i>vr</i> and <i>vi</i> contain the real and imaginary parts</p>
-----------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

of the computed complex eigenvector. The eigenvector is normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x| + |y|$.
 vi is not referenced if $wi = 0.0$.

v On exit, v contains the computed eigenvector, normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x| + |y|$.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = 1$, inverse iteration did not converge. For real flavors, vr is set to the last iterate, and so is vi , if $wi \neq 0.0$. For complex flavors, v is set to the last iterate.

?laev2

Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.

Syntax

```
call slaev2( a, b, c, rt1, rt2, cs1, sn1 )
call dlaev2( a, b, c, rt1, rt2, cs1, sn1 )
call claev2( a, b, c, rt1, rt2, cs1, sn1 )
call zlaev2( a, b, c, rt1, rt2, cs1, sn1 )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix} \text{ (for } slaev2/dlaev2 \text{) or Hermitian matrix } \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix}$$

(for `claev2/zlaev2`).

On return, `rt1` is the eigenvalue of larger absolute value, `rt2` of smaller absolute value, and `(cs1, sn1)` is the unit right eigenvector for `rt1`, giving the decomposition

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for `slaev2/dlaev2`),

or

$$\begin{bmatrix} cs1 & \text{conjg}(sn1) \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -\text{conjg}(sn1) \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for `claev2/zlaev2`).

Input Parameters

`a, b, c` REAL for `slaev2`
 DOUBLE PRECISION for `dlaev2`
 COMPLEX for `claev2`
 COMPLEX*16 for `zlaev2`.
 Elements of the input matrix.

Output Parameters

`rt1, rt2` REAL for `slaev2/claev2`
 DOUBLE PRECISION for `dlaev2/zlaev2`.
 Eigenvalues of larger and smaller absolute value,
 respectively.

`cs1` REAL for `slaev2/claev2`
 DOUBLE PRECISION for `dlaev2/zlaev2`.

`sn1` REAL for `slaev2`
 DOUBLE PRECISION for `dlaev2`
 COMPLEX for `claev2`

COMPLEX*16 for zlaev2.

The vector (*cs1*, *sn1*) is the unit right eigenvector for *rt1*.

Application Notes

rt1 is accurate to a few ulps barring over/underflow. *rt2* may be inaccurate if there is massive cancellation in the determinant $a*c-b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute *rt2* accurately in all cases. *cs1* and *sn1* are accurate to a few ulps barring over/underflow. Overflow is possible only if *rt1* is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds *underflow_threshold* / macheps.

?laexc

Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.

Syntax

```
call slaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
```

```
call dlaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine swaps adjacent diagonal blocks T_{11} and T_{22} of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

wantq

LOGICAL.

If *wantq* = .TRUE., accumulate the transformation in the matrix Q ;

If *wantq* = .FALSE., do not accumulate the transformation.

n INTEGER. The order of the matrix T ($n \geq 0$).

t, q REAL for slaexc
DOUBLE PRECISION for dlaexc
Arrays:
t(*ldt*,*) contains on entry the upper quasi-triangular matrix T , in Schur canonical form.
The second dimension of *t* must be at least $\max(1, n)$.
q(*ldq*,*) contains on entry, if *wantq* = .TRUE., the orthogonal matrix Q . If *wantq* = .FALSE., *q* is not referenced. The second dimension of *q* must be at least $\max(1, n)$.

ldt INTEGER. The first dimension of *t*; at least $\max(1, n)$.

ldq INTEGER. The first dimension of *q*;
If *wantq* = .FALSE., then *ldq* ≥ 1 .
If *wantq* = .TRUE., then *ldq* $\geq \max(1, n)$.

j1 INTEGER. The index of the first row of the first block T_{11} .

n1 INTEGER. The order of the first block T_{11}
(*n1* = 0, 1, or 2).

n2 INTEGER. The order of the second block T_{22}
(*n2* = 0, 1, or 2).

work REAL for slaexc;
DOUBLE PRECISION for dlaexc.
Workspace array, DIMENSION (*n*).

Output Parameters

t On exit, the updated matrix T , again in Schur canonical form.

q On exit, if *wantq* = .TRUE., the updated matrix Q .

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = 1, the transformed matrix T would be too far from Schur form; the blocks are not swapped and T and Q are unchanged.

?lag2

Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.

Syntax

```
call slag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
call dlag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the eigenvalues of a 2 x 2 generalized eigenvalue problem $A - w * B$, with scaling as necessary to avoid over-/underflow. The scaling factor, s , results in a modified eigenvalue equation

$$s * A - w * B,$$

where s is a non-negative scaling factor chosen so that w , $w * B$, and $s * A$ do not overflow and, if possible, do not underflow, either.

Input Parameters

a, b	REAL for slag2 DOUBLE PRECISION for dlag2
	Arrays:
	$a(lda, 2)$ contains, on entry, the 2 x 2 matrix A . It is assumed that its 1-norm is less than $1/safmin$. Entries less than $\text{sqrt}(safmin) * \text{norm}(A)$ are subject to being treated as zero.
	$b(ldb, 2)$ contains, on entry, the 2 x 2 upper triangular matrix B . It is assumed that the one-norm of B is less than $1/safmin$. The diagonals should be at least $\text{sqrt}(safmin)$ times the largest element of B (in absolute value); if a diagonal is smaller than that, then $\pm \text{sqrt}(safmin)$ will be used instead of that diagonal.
lda	INTEGER. The first dimension of a ; $lda \geq 2$.

ldb INTEGER. The first dimension of *b*; $ldb \geq 2$.

safmin REAL for *slag2*;
 DOUBLE PRECISION for *dlag2*.
 The smallest positive number such that $1/safmin$ does not overflow. (This should always be `?lamch('S')` - it is an argument in order to avoid having to call `?lamch` frequently.)

Output Parameters

scale1 REAL for *slag2*;
 DOUBLE PRECISION for *dlag2*.
 A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the first eigenvalue. If the eigenvalues are complex, then the eigenvalues are $(wr1 \pm wii)/scale1$ (which may lie outside the exponent range of the machine), $scale1=scale2$, and $scale1$ will always be positive.
 If the eigenvalues are real, then the first (real) eigenvalue is $wr1/scale1$, but this may overflow or underflow, and in fact, $scale1$ may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

scale2 REAL for *slag2*;
 DOUBLE PRECISION for *dlag2*.
 A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the second eigenvalue. If the eigenvalues are complex, then $scale2=scale1$. If the eigenvalues are real, then the second (real) eigenvalue is $wr2/scale2$, but this may overflow or underflow, and in fact, $scale2$ may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

wr1 REAL for *slag2*;
 DOUBLE PRECISION for *dlag2*.
 If the eigenvalue is real, then *wr1* is $scale1$ times the eigenvalue closest to the (2,2) element of $A \cdot inv(B)$.
 If the eigenvalue is complex, then $wr1=wr2$ is $scale1$ times the real part of the eigenvalues.

wr2 REAL for *slag2*;

wi

DOUBLE PRECISION for dlag2.
 If the eigenvalue is real, then *wr2* is *scale2* times the other eigenvalue. If the eigenvalue is complex, then *wr1=wr2* is *scale1* times the real part of the eigenvalues.

REAL for slag2;
 DOUBLE PRECISION for dlag2.
 If the eigenvalue is real, then *wi* is zero. If the eigenvalue is complex, then *wi* is *scale1* times the imaginary part of the eigenvalues. *wi* will always be non-negative.

?lags2

Computes 2-by-2 orthogonal matrices U, V, and Q, and applies them to matrices A and B such that the rows of the transformed A and B are parallel.

Syntax

```
call slags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq )
call dlags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes 2-by-2 orthogonal matrices *U*, *V* and *Q*, such that if *upper* = `.TRUE.`, then

$$U^* A Q = U^* \begin{bmatrix} A_1 & A_2 \\ 0 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

and

$$V^* B Q = V^* \begin{bmatrix} B_1 & B_2 \\ 0 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

or if `upper = .FALSE.`, then

$$U^* A Q = U^* \begin{bmatrix} A_1 & 0 \\ A_2 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

and

$$V^* B Q = V^* \begin{bmatrix} B_1 & 0 \\ B_2 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

The rows of the transformed A and B are parallel, where

$$U = \begin{bmatrix} csu & snu \\ -snu & csu \end{bmatrix}, V = \begin{bmatrix} csv & snv \\ -snv & csv \end{bmatrix}, Q = \begin{bmatrix} csq & snq \\ -snq & csq \end{bmatrix}$$

Here Z' denotes the transpose of Z .

Input Parameters

<code>upper</code>	LOGICAL. If <code>upper = .TRUE.</code> , the input matrices A and B are upper triangular; If <code>upper = .FALSE.</code> , the input matrices A and B are lower triangular.
<code>a1, a2, a3</code>	REAL for <code>slags2</code> DOUBLE PRECISION for <code>dlags2</code> On entry, <code>a1</code> , <code>a2</code> and <code>a3</code> are elements of the input 2-by-2 upper (lower) triangular matrix A .
<code>b1, b2, b3</code>	REAL for <code>slags2</code> DOUBLE PRECISION for <code>dlags2</code> On entry, <code>b1</code> , <code>b2</code> and <code>b3</code> are elements of the input 2-by-2 upper (lower) triangular matrix B .

Output Parameters

<i>csu, snu</i>	REAL for slags2 DOUBLE PRECISION for dlags2 The desired orthogonal matrix U .
<i>csv, snv</i>	REAL for slags2 DOUBLE PRECISION for dlags2 The desired orthogonal matrix V .
<i>csq, snq</i>	REAL for slags2 DOUBLE PRECISION for dlags2 The desired orthogonal matrix Q .

?lagtf

*Computes an LU factorization of a matrix $T - \lambda * I$, where T is a general tridiagonal matrix, and λ is a scalar, using partial pivoting with row interchanges.*

Syntax

```
call slagtf( n, a, lambda, b, c, tol, d, in, info )
call dlagtf( n, a, lambda, b, c, tol, d, in, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine factorizes the matrix $(T - \lambda * I)$, where T is an n -by- n tridiagonal matrix and λ is a scalar, as

$$T - \lambda * I = P * L * U,$$

where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column. The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling. The parameter `lambda` is included in the routine so that `?lagtf` may be used, in conjunction with `?lagts`, to obtain eigenvectors of T by inverse iteration.

Input Parameters

n	INTEGER. The order of the matrix T ($n \geq 0$).
a, b, c	REAL for <code>slagtf</code> DOUBLE PRECISION for <code>dlagtf</code> Arrays, dimension $a(n)$, $b(n-1)$, $c(n-1)$: On entry, $a(*)$ must contain the diagonal elements of the matrix T . On entry, $b(*)$ must contain the $(n-1)$ super-diagonal elements of T . On entry, $c(*)$ must contain the $(n-1)$ sub-diagonal elements of T .
tol	REAL for <code>slagtf</code> DOUBLE PRECISION for <code>dlagtf</code> On entry, a relative tolerance used to indicate whether or not the matrix $(T - \lambda I)$ is nearly singular. tol should normally be chosen as approximately the largest relative error in the elements of T . For example, if the elements of T are correct to about 4 significant figures, then tol should be set to about 5×10^{-4} . If tol is supplied as less than <code>eps</code> , where <code>eps</code> is the relative machine precision, then the value <code>eps</code> is used in place of tol .

Output Parameters

a	On exit, a is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T .
b	On exit, b is overwritten by the $n-1$ super-diagonal elements of the matrix U of the factorization of T .
c	On exit, c is overwritten by the $n-1$ sub-diagonal elements of the matrix L of the factorization of T .
d	REAL for <code>slagtf</code> DOUBLE PRECISION for <code>dlagtf</code> Array, dimension $(n-2)$. On exit, d is overwritten by the $n-2$ second super-diagonal elements of the matrix U of the factorization of T .
in	INTEGER.

Array, dimension (n).

On exit, in contains details of the permutation matrix p . If an interchange occurred at the k -th step of the elimination, then $in(k) = 1$, otherwise $in(k) = 0$. The element $in(n)$ returns the smallest positive integer j such that

$$\text{abs}(u(j,j)) \leq \text{norm}((T - \text{lambda}*I)(j))*tol,$$

where $\text{norm}(A(j))$ denotes the sum of the absolute values of the j -th row of the matrix A .

If no such j exists then $in(n)$ is returned as zero. If $in(n)$ is returned as positive, then a diagonal element of U is small, indicating that $(T - \text{lambda}*I)$ is singular or nearly singular.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -k$, the k -th parameter had an illegal value.

?lagtm

*Performs a matrix-matrix product of the form $C = \alpha*A*B + \beta*C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.*

Syntax

```
call slagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call dlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call clagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call zlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine performs a matrix-vector product of the form:

$$B := \alpha*A*X + \beta*B$$

where A is a tridiagonal matrix of order n , B and X are n -by- $nrhs$ matrices, and α and β are real scalars, each of which may be 0., 1., or -1.

Input Parameters

<i>trans</i>	<p>CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>Indicates the form of the equations:</p> <p>If <i>trans</i> = 'N', then $B := \alpha A X + \beta B$ (no transpose);</p> <p>If <i>trans</i> = 'T', then $B := \alpha A^T X + \beta B$ (transpose);</p> <p>If <i>trans</i> = 'C', then $B := \alpha A^H X + \beta B$ (conjugate transpose)</p>
<i>n</i>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides, i.e., the number of columns in X and B ($nrhs \geq 0$).</p>
<i>alpha, beta</i>	<p>REAL for slagtm/clagtm</p> <p>DOUBLE PRECISION for dlagtm/zlagtm</p> <p>Specify the scalars <i>alpha</i> and <i>beta</i> respectively. <i>alpha</i> must be 0., 1., or -1.; otherwise, it is assumed to be 0. <i>beta</i> must be 0., 1., or -1.; otherwise, it is assumed to be 1.</p>
<i>dl, d, du</i>	<p>REAL for slagtm</p> <p>DOUBLE PRECISION for dlagtm</p> <p>COMPLEX for clagtm</p> <p>COMPLEX*16 for zlagtm.</p> <p>Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$.</p> <p>The array <i>dl</i> contains the $(n-1)$ sub-diagonal elements of T.</p> <p>The array <i>d</i> contains the n diagonal elements of T.</p> <p>The array <i>du</i> contains the $(n-1)$ super-diagonal elements of T.</p>
<i>x, b</i>	<p>REAL for slagtm</p> <p>DOUBLE PRECISION for dlagtm</p> <p>COMPLEX for clagtm</p> <p>COMPLEX*16 for zlagtm.</p> <p>Arrays:</p>

$x(ldx,*)$ contains the n -by- $nrhs$ matrix X . The second dimension of x must be at least $\max(1, nrhs)$.

$b(ldb,*)$ contains the n -by- $nrhs$ matrix B . The second dimension of b must be at least $\max(1, nrhs)$.

ldx INTEGER. The leading dimension of the array x ; $ldx \geq \max(1, n)$.

ldb INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the matrix expression $B := \alpha A * X + \beta B$

?lagts

*Solves the system of equations $(T - \lambda I) * x = y$ or $(T - \lambda I)^T * x = y$, where T is a general tridiagonal matrix and λ is a scalar, using the LU factorization computed by ?lagtf.*

Syntax

```
call slagts( job, n, a, b, c, d, in, y, tol, info )
```

```
call dlagts( job, n, a, b, c, d, in, y, tol, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine may be used to solve for x one of the systems of equations:

$$(T - \lambda I) * x = y \quad \text{or} \quad (T - \lambda I)^T * x = y,$$

where T is an n -by- n tridiagonal matrix, following the factorization of $(T - \lambda I)$ as

$$T - \lambda I = P * L * U,$$

computed by the routine ?lagtf.

The choice of equation to be solved is controlled by the argument *job*, and in each case there is an option to perturb zero or very small diagonal elements of *U*, this option being intended for use in applications such as inverse iteration.

Input Parameters

<i>job</i>	<p>INTEGER. Specifies the job to be performed by ?lagts as follows:</p> <p>= 1: The equations $(T - \lambda I)x = y$ are to be solved, but diagonal elements of <i>U</i> are not to be perturbed.</p> <p>= -1: The equations $(T - \lambda I)x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of <i>U</i> are to be perturbed. See argument <i>tol</i> below.</p> <p>= 2: The equations $(T - \lambda I)^T x = y$ are to be solved, but diagonal elements of <i>U</i> are not to be perturbed.</p> <p>= -2: The equations $(T - \lambda I)^T x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of <i>U</i> are to be perturbed. See argument <i>tol</i> below.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>T</i> ($n \geq 0$).</p>
<i>a, b, c, d</i>	<p>REAL for slagts DOUBLE PRECISION for dlagts Arrays, dimension <i>a</i>(<i>n</i>), <i>b</i>(<i>n</i>-1), <i>c</i>(<i>n</i>-1), <i>d</i>(<i>n</i>-2): On entry, <i>a</i>(*) must contain the diagonal elements of <i>U</i> as returned from ?lagtf. On entry, <i>b</i>(*) must contain the first super-diagonal elements of <i>U</i> as returned from ?lagtf. On entry, <i>c</i>(*) must contain the sub-diagonal elements of <i>L</i> as returned from ?lagtf. On entry, <i>d</i>(*) must contain the second super-diagonal elements of <i>U</i> as returned from ?lagtf.</p>
<i>in</i>	<p>INTEGER. Array, dimension (<i>n</i>). On entry, <i>in</i>(*) must contain details of the matrix <i>p</i> as returned from ?lagtf.</p>
<i>y</i>	<p>REAL for slagts DOUBLE PRECISION for dlagts Array, dimension (<i>n</i>). On entry, the right hand side vector <i>y</i>.</p>

tol REAL for `slagtf`
DOUBLE PRECISION for `dlagtf`.
On entry, with *job* < 0, *tol* should be the minimum perturbation to be made to very small diagonal elements of *U*. *tol* should normally be chosen as about *eps***norm(U)*, where *eps* is the relative machine precision, but if *tol* is supplied as non-positive, then it is reset to *eps***max(abs(u(i,j)))*. If *job* > 0 then *tol* is not referenced.

Output Parameters

y On exit, *y* is overwritten by the solution vector *x*.
tol On exit, *tol* is changed as described in *Input Parameters* section above, only if *tol* is non-positive on entry. Otherwise *tol* is unchanged.
info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value. If *info* = *i* > 0, overflow would occur when computing the *i*th element of the solution vector *x*. This can only occur when *job* is supplied as positive and either means that a diagonal element of *U* is very small, or that the elements of the right-hand side vector *y* are very large.

?lagv2

Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A,B) where B is upper triangular.

Syntax

```
call slagv2( a, lda, b, ldb, alphas, alphai, beta, csl, snl, csr, snr )
call dlagv2( a, lda, b, ldb, alphas, alphai, beta, csl, snl, csr, snr )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A, B) where B is upper triangular. The routine computes orthogonal (rotation) matrices given by $cs1$, $sn1$ and csr , snr such that:

1) if the pencil (A, B) has two real eigenvalues (include 0/0 or 1/0 types), then

$$\begin{bmatrix} a_{11} & a_{12} \\ 0 & a_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

2) if the pencil (A, B) has a pair of complex conjugate eigenvalues, then

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & 0 \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

where $b_{11} \geq b_{22} > 0$.

Input Parameters

a, b

REAL for `slagv2`

DOUBLE PRECISION for `dlagv2`

Arrays:

$a(lda, 2)$ contains the 2-by-2 matrix A ;

$b(lb, 2)$ contains the upper triangular 2-by-2 matrix B .

lda

INTEGER. The leading dimension of the array a ;

lda ≥ 2 .
ldb INTEGER. The leading dimension of the array *b*;
ldb ≥ 2 .

Output Parameters

a On exit, *a* is overwritten by the “A-part” of the generalized Schur form.

b On exit, *b* is overwritten by the “B-part” of the generalized Schur form.

alphar, alphai, beta REAL for `slagv2`
DOUBLE PRECISION for `dlagv2`.
Arrays, dimension (2) each.
(*alphar*(*k*) + *i***alphai*(*k*))/*beta*(*k*) are the
eigenvalues of the pencil (*A*,*B*), *k*=1,2 and *i* = `sqrt(-1)`.
Note that *beta*(*k*) may be zero.

cs1, sn1 REAL for `slagv2`
DOUBLE PRECISION for `dlagv2`
The cosine and sine of the left rotation matrix, respectively.

csr, snr REAL for `slagv2`
DOUBLE PRECISION for `dlagv2`
The cosine and sine of the right rotation matrix, respectively.

?lahqr

Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.

Syntax

```
call slahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
info )
```

```
call dlahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
info )
```

```
call clahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info
)
```

```
call zlahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info
)
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine is an auxiliary routine called by [?hseqr](#) to update the eigenvalues and Schur decomposition already computed by [?hseqr](#), by dealing with the Hessenberg submatrix in rows and columns *ilo* to *ihi*.

Input Parameters

<i>wantt</i>	LOGICAL. If <i>wantt</i> = <code>.TRUE.</code> , the full Schur form <i>T</i> is required; If <i>wantt</i> = <code>.FALSE.</code> , eigenvalues only are required.
<i>wantz</i>	LOGICAL. If <i>wantz</i> = <code>.TRUE.</code> , the matrix of Schur vectors <i>Z</i> is required; If <i>wantz</i> = <code>.FALSE.</code> , Schur vectors are not required.
<i>n</i>	INTEGER. The order of the matrix <i>H</i> ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER.

It is assumed that h is already upper quasi-triangular in rows and columns $ihi+1:n$, and that $h(ilo, ilo-1) = 0$ (unless $ilo = 1$). The routine `?lahqr` works primarily with the Hessenberg submatrix in rows and columns ilo to ihi , but applies transformations to all of h if $wantt = .TRUE..$
Constraints:

$1 \leq ilo \leq \max(1, ihi); ihi \leq n.$

h, z

REAL for `slahqr`
DOUBLE PRECISION for `dlahqr`
COMPLEX for `clahqr`
COMPLEX*16 for `zlahqr`.

Arrays:

$h(ldh,*)$ contains the upper Hessenberg matrix h .

The second dimension of h must be at least $\max(1, n)$.

$z(ldz,*)$

If $wantz = .TRUE.$, then, on entry, z must contain the current matrix z of transformations accumulated by `?hseqr`.

If $wantz = .FALSE.$, then z is not referenced. The second dimension of z must be at least $\max(1, n)$.

ldh

INTEGER. The first dimension of h ; at least $\max(1, n)$.

ldz

INTEGER. The first dimension of z ; at least $\max(1, n)$.

$iloz, ihiz$

INTEGER. Specify the rows of z to which transformations must be applied if $wantz = .TRUE..$

$1 \leq iloz \leq ilo; ihi \leq ihiz \leq n.$

Output Parameters

h

On exit, if $info=0$ and $wantt = .TRUE.$, then,

- for `slahqr/dlahqr`, h is upper quasi-triangular in rows and columns $ilo:ihi$ with any 2-by-2 diagonal blocks in standard form.
- for `clahqr/zlahqr`, h is upper triangular in rows and columns $ilo:ihi$.

If *info* = 0 and *wantt* = *.FALSE.*, the contents of *h* are unspecified on exit. If *info* is positive, see description of *info* for the output state of *h*.

wr, wi REAL for *slahqr*
 DOUBLE PRECISION for *dlahqr*
 Arrays, DIMENSION at least $\max(1, n)$ each. Used with real flavors only. The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)-th, with *wi*(*i*) > 0 and *wi*(*i*+1) < 0.
 If *wantt* = *.TRUE.*, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *wr*(*i*) = *h*(*i*,*i*), and, if *h*(*i*:*i*+1, *i*:*i*+1) is a 2-by-2 diagonal block, *wi*(*i*) = $\sqrt{h(i+1,i)*h(i,i+1)}$ and *wi*(*i*+1) = -*wi*(*i*).

w COMPLEX for *clahqr*
 COMPLEX*16 for *zlahqr*.
 Array, DIMENSION at least $\max(1, n)$. Used with complex flavors only. The computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *w*.
 If *wantt* = *.TRUE.*, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *w*(*i*) = *h*(*i*,*i*).

z If *wantz* = *.TRUE.*, then, on exit *z* has been updated; transformations are applied only to the submatrix *z*(*iloz*:*ihiz*, *ilo*:*ihi*).

info INTEGER.
 If *info* = 0, the execution is successful.
 With *info* > 0,

- if *info* = *i*, ?*lahqr* failed to compute all the eigenvalues *ilo* to *ihi* in a total of 30 iterations per eigenvalue; elements *i*+1:*ihi* of *wr* and *wi* (for *slahqr*/*dlahqr*) or *w* (for *clahqr*/*zlahqr*) contain those eigenvalues which have been successfully computed.

- if *wantt* is `.FALSE.`, then on exit the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final output value of *h*.
- if *wantt* is `.TRUE.`, then on exit
(initial value of *h*)**u* = *u**(final value of *h*),
(*)
where *u* is an orthognal matrix. The final value of *h* is upper Hessenberg and triangular in rows and columns *info+1* through *ihi*.
- if *wantz* is `.TRUE.`, then on exit
(final value of *z*) = (initial value of *z*)* *u*,

where *u* is an orthognal matrix in (*) regardless of the value of *wantt*.

?lahrd

*Reduces the first *nb* columns of a general rectangular matrix *A* so that elements below the *k*-th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of *A*.*

Syntax

```
call slahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call dlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call clahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call zlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine reduces the first nb columns of a real/complex general n -by- $(n-k+1)$ matrix A so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q'^*A^*Q . The routine returns the matrices V and T which determine Q as a block reflector $I - V^*T^*V'$, and also the matrix $Y = A^*V^*T$.

The matrix Q is represented as products of nb elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector.

This is an obsolete auxiliary routine. Please use the new routine `zlahr2` instead.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
k	INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
nb	INTEGER. The number of columns to be reduced.
a	REAL for <code>slahrd</code> DOUBLE PRECISION for <code>dlahrd</code> COMPLEX for <code>clahrd</code> COMPLEX*16 for <code>zlahrd</code> . Array $a(lda, n-k+1)$ contains the n -by- $(n-k+1)$ general matrix A to be reduced.
lda	INTEGER. The first dimension of a ; at least $\max(1, n)$.
ldt	INTEGER. The first dimension of the output array t ; must be at least $\max(1, nb)$.
ldy	INTEGER. The first dimension of the output array y ; must be at least $\max(1, n)$.

Output Parameters

a	On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced matrix; the elements
-----	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------

below the k -th subdiagonal, with the array τ , represent the matrix Q as a product of elementary reflectors. The other columns of a are unchanged. See *Application Notes* below.

τ	<p>REAL for slahrd DOUBLE PRECISION for dlahrd COMPLEX for clahrd COMPLEX*16 for zlahrd. Array, DIMENSION (nb). Contains scalar factors of the elementary reflectors.</p>
t, y	<p>REAL for slahrd DOUBLE PRECISION for dlahrd COMPLEX for clahrd COMPLEX*16 for zlahrd. Arrays, dimension $t(ldt, nb)$, $y(ldy, nb)$. The array t contains upper triangular matrix T. The array y contains the n-by-nb matrix Y.</p>

Application Notes

For the elementary reflector $H(i)$,

$v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $a(i+k+1:n, i)$ and τ is stored in $\tau(i)$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form:

$$A := (I - V^* T^* V') * (A - Y^* V').$$

The contents of A on exit are illustrated by the following example with $n = 7$, $k = 3$ and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?lahr2

Reduces the specified number of first columns of a general rectangular matrix A so that elements below the specified subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .

Syntax

```
call slahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call dlahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call clahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call zlahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine reduces the first nb columns of a real/complex general n -by- $(n-k+1)$ matrix A so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q'^*A*Q . The routine returns the matrices V and T which determine Q as a block reflector $I - V*T*V'$, and also the matrix $Y = A*V*T$.

The matrix Q is represented as products of nb elementary reflectors:

$$Q = H(1)*H(2)*\dots *H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau*v*v'$$

where τ is a real/complex scalar, and v is a real/complex vector.

This is an auxiliary routine called by `?gehrd`.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
k	INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero ($k < n$).
nb	INTEGER. The number of columns to be reduced.
a	REAL for <code>slahr2</code> DOUBLE PRECISION for <code>dlahr2</code> COMPLEX for <code>clahr2</code> COMPLEX*16 for <code>zlahr2</code> . Array, DIMENSION ($lda, n-k+1$) contains the n -by- $(n-k+1)$ general matrix A to be reduced.
lda	INTEGER. The first dimension of the array a ; $lda \geq \max(1, n)$.
ldt	INTEGER. The first dimension of the output array t ; $ldt \geq nb$.
ldy	INTEGER. The first dimension of the output array y ; $ldy \geq n$.

Output Parameters

<i>a</i>	On exit, the elements on and above the <i>k</i> -th subdiagonal in the first <i>nb</i> columns are overwritten with the corresponding elements of the reduced matrix; the elements below the <i>k</i> -th subdiagonal, with the array <i>tau</i> , represent the matrix <i>Q</i> as a product of elementary reflectors. The other columns of <i>a</i> are unchanged. See <i>Application Notes</i> below.
<i>tau</i>	REAL for slahr2 DOUBLE PRECISION for dlahr2 COMPLEX for clahr2 COMPLEX*16 for zlahr2. Array, DIMENSION (<i>nb</i>). Contains scalar factors of the elementary reflectors.
<i>t, y</i>	REAL for slahr2 DOUBLE PRECISION for dlahr2 COMPLEX for clahr2 COMPLEX*16 for zlahr2. Arrays, dimension <i>t</i> (<i>ldt</i> , <i>nb</i>), <i>y</i> (<i>ldy</i> , <i>nb</i>). The array <i>t</i> contains upper triangular matrix <i>T</i> . The array <i>y</i> contains the <i>n</i> -by- <i>nb</i> matrix <i>Y</i> .

Application Notes

For the elementary reflector $H(i)$,

$v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $a(i+k+1:n, i)$ and *tau* is stored in *tau*(*i*).

The elements of the vectors *v* together form the (*n-k+1*)-by-*nb* matrix *V* which is needed, with *T* and *Y*, to apply the transformation to the unreduced part of the matrix, using an update of the form:

$$A := (I - V^* T^* V') * (A - Y^* V').$$

The contents of *A* on exit are illustrated by the following example with $n = 7$, $k = 3$ and $nb = 2$:

$$\begin{bmatrix} a & a & a & a & a \\ a & a & a & a & a \\ a & a & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?laic1

Applies one step of incremental condition estimation.

Syntax

```
call slaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call dlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call claic1( job, j, x, sest, w, gamma, sestpr, s, c )
call zlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?laic1` applies one step of incremental condition estimation in its simplest version.

Let x , $\|x\|_2 = 1$ (where $\|a\|_2$ denotes the 2-norm of a), be an approximate singular vector of an j -by- j lower triangular matrix L , such that

$$\|Lx\|_2 = \text{sest}$$

Then `?laic1` computes `sestpr`, `s`, `c` such that the vector

$$\mathbf{xhat} = \begin{bmatrix} \mathbf{s}^* \mathbf{x} \\ \mathbf{c} \end{bmatrix}$$

is an approximate singular vector of

$$\mathbf{Lhat} = \begin{bmatrix} L & 0 \\ \mathbf{w}' & \mathbf{gamma} \end{bmatrix}$$

in the sense that

$$||\mathbf{Lhat} * \mathbf{xhat}||_2 = \mathbf{sestpr}.$$

Depending on *job*, an estimate for the largest or smallest singular value is computed.

Note that $[\mathbf{s} \ \mathbf{c}]'$ and \mathbf{sestpr}^2 is an eigenpair of the system (for `slaic1/claic`)

$$\text{diag}(\mathbf{sest} * \mathbf{sest}, 0) + [\mathbf{alpha} \ \mathbf{gamma}] * \begin{bmatrix} \mathbf{alpha} \\ \mathbf{gamma} \end{bmatrix}$$

where $\mathbf{alpha} = \mathbf{x}' * \mathbf{w}$;

or of the system (for `claic1/zlaic`)

$$\text{diag}(\mathbf{sest} * \mathbf{sest}, 0) + [\mathbf{alpha} \ \mathbf{gamma}] * \begin{bmatrix} \text{conjg}(\mathbf{alpha}) \\ \text{conjg}(\mathbf{gamma}) \end{bmatrix}$$

where $\mathbf{alpha} = \text{conjg}(\mathbf{x})' * \mathbf{w}$.

Input Parameters

job

INTEGER.

If *job* =1, an estimate for the largest singular value is computed;

If $job = 2$, an estimate for the smallest singular value is computed;

j	INTEGER. Length of x and w .
x, w	REAL for slaic1 DOUBLE PRECISION for dlaic1 COMPLEX for claic1 COMPLEX*16 for zlaic1. Arrays, dimension (j) each. Contain vectors x and w , respectively.
$sest$	REAL for slaic1/claic1; DOUBLE PRECISION for dlaic1/zlaic1. Estimated singular value of j -by- j matrix L .
$gamma$	REAL for slaic1 DOUBLE PRECISION for dlaic1 COMPLEX for claic1 COMPLEX*16 for zlaic1. The diagonal element $gamma$.

Output Parameters

$sestpr$	REAL for slaic1/claic1; DOUBLE PRECISION for dlaic1/zlaic1. Estimated singular value of $(j+1)$ -by- $(j+1)$ matrix $Lhat$.
s, c	REAL for slaic1 DOUBLE PRECISION for dlaic1 COMPLEX for claic1 COMPLEX*16 for zlaic1. Sine and cosine needed in forming $xhat$.

?laln2

Solves a 1-by-1 or 2-by-2 linear system of equations of the specified form.

Syntax

```
call slaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx,
scale, xnorm, info )
```

```
call dlaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx,
scale, xnorm, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine solves a system of the form

$$(ca*A - w*D)*X = s*B, \text{ or } (ca*A' - w*D)*X = s*B$$

with possible scaling (s) and perturbation of A (A' means A -transpose.)

A is an na -by- na real matrix, ca is a real scalar, D is an na -by- na real diagonal matrix, w is a real or complex value, and X and B are na -by-1 matrices: real if w is real, complex if w is complex. The parameter na may be 1 or 2.

If w is complex, X and B are represented as na -by-2 matrices, the first column of each being the real part and the second being the imaginary part.

The routine computes the scaling factor s (≤ 1) so chosen that X can be computed without overflow. X is further scaled if necessary to assure that $\text{norm}(ca*A - w*D)*\text{norm}(X)$ is less than overflow.

If both singular values of $(ca*A - w*D)$ are less than $smin$, $smin*I$ (where I stands for identity) will be used instead of $(ca*A - w*D)$. If only one singular value is less than $smin$, one element of $(ca*A - w*D)$ will be perturbed enough to make the smallest singular value roughly $smin$.

If both singular values are at least $smin$, $(ca*A - w*D)$ will not be perturbed. In any case, the perturbation will be at most some small multiple of $\max(smin, \text{ulp}*\text{norm}(ca*A - w*D))$.

The singular values are computed by infinity-norm approximations, and thus will only be correct to a factor of 2 or so.

NOTE. All input quantities are assumed to be smaller than overflow by a reasonable factor (see *bignum*).

Input Parameters

<i>trans</i>	<p>LOGICAL.</p> <p>If <i>trans</i> = <code>.TRUE.</code>, <i>A</i>-transpose will be used.</p> <p>If <i>trans</i> = <code>.FALSE.</code>, <i>A</i> will be used (not transposed.)</p>
<i>na</i>	<p>INTEGER. The size of the matrix <i>A</i>, possible values 1 or 2.</p>
<i>nw</i>	<p>INTEGER. This parameter must be 1 if <i>w</i> is real, and 2 if <i>w</i> is complex. Possible values 1 or 2.</p>
<i>smin</i>	<p>REAL for <code>slaln2</code></p> <p>DOUBLE PRECISION for <code>dlaln2</code>.</p> <p>The desired lower bound on the singular values of <i>A</i>.</p> <p>This should be a safe distance away from underflow or overflow, for example, between (<i>underflow/machine_precision</i>) and (<i>machine_precision * overflow</i>). (See <i>bignum</i> and <i>ulp</i>).</p>
<i>ca</i>	<p>REAL for <code>slaln2</code></p> <p>DOUBLE PRECISION for <code>dlaln2</code>.</p> <p>The coefficient by which <i>A</i> is multiplied.</p>
<i>a</i>	<p>REAL for <code>slaln2</code></p> <p>DOUBLE PRECISION for <code>dlaln2</code>.</p> <p>Array, DIMENSION (<i>lda,na</i>).</p> <p>The <i>na</i>-by-<i>na</i> matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of <i>a</i>. Must be at least <i>na</i>.</p>
<i>d1, d2</i>	<p>REAL for <code>slaln2</code></p> <p>DOUBLE PRECISION for <code>dlaln2</code>.</p> <p>The (1,1) and (2,2) elements in the diagonal matrix <i>D</i>, respectively. <i>d2</i> is not used if <i>nw</i> = 1.</p>
<i>b</i>	<p>REAL for <code>slaln2</code></p> <p>DOUBLE PRECISION for <code>dlaln2</code>.</p> <p>Array, DIMENSION (<i>ldb,nw</i>). The <i>na</i>-by-<i>nw</i> matrix <i>B</i> (right-hand side). If <i>nw</i>=2 (<i>w</i> is complex), column 1 contains the real part of <i>B</i> and column 2 contains the imaginary part.</p>

ldb INTEGER. The leading dimension of *b*. Must be at least *na*.

wr, wi REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.
The real and imaginary part of the scalar *w*, respectively.
wi is not used if *nw* = 1.

ldx INTEGER. The leading dimension of the output array *x*. Must be at least *na*.

Output Parameters

x REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.
Array, DIMENSION (*ldx*,*nw*). The *na*-by-*nw* matrix *X* (unknowns), as computed by the routine. If *nw* = 2 (*w* is complex), on exit, column 1 will contain the real part of *X* and column 2 will contain the imaginary part.

scale REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.
The scale factor that *B* must be multiplied by to insure that overflow does not occur when computing *X*. Thus $(ca*A - w*D) X$ will be *scale***B*, not *B* (ignoring perturbations of *A*.) It will be at most 1.

xnorm REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.
The infinity-norm of *X*, when *X* is regarded as an *na*-by-*nw* real matrix.

info INTEGER.
An error flag. It will be zero if no error occurs, a negative number if an argument is in error, or a positive number if $(ca*A - w*D)$ had to be perturbed. The possible values are:
If *info* = 0: no error occurred, and $(ca*A - w*D)$ did not have to be perturbed.
If *info* = 1: $(ca*A - w*D)$ had to be perturbed to make its smallest (or only) singular value greater than *smin*.

NOTE. For higher speed, this routine does not check the inputs for errors.

slals0

Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd.

Syntax

```
call slals0 (  icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
               givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )

call dlals0 (  icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
               givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )

call clals0(  icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
               givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )

call zlals0(  icompq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
               givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine applies back the multiplying factors of either the left or right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix *B* in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is *givptr*; the pairs of columns/rows they were applied to are stored in *givcol*; and the *c*- and *s*-values of these rotations are stored in *givnum*.

(2L) Permutation. The (*nl*+1)-st row of *B* is to be moved to the first row, and for *j*=2:*n*, *perm*(*j*)-th row of *B* is to be moved to the *j*-th row.

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If *sqre* = 1, one extra Givens rotation to generate the right null space.

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Input Parameters

<i>icompq</i>	<p>INTEGER. Specifies whether singular vectors are to be computed in factored form:</p> <p>If <i>icompq</i> = 0: Left singular vector matrix.</p> <p>If <i>icompq</i> = 1: Right singular vector matrix.</p>
<i>nl</i>	<p>INTEGER. The row dimension of the upper block.</p> <p>$nl \geq 1$.</p>
<i>nr</i>	<p>INTEGER. The row dimension of the lower block.</p> <p>$nr \geq 1$.</p>
<i>sqre</i>	<p>INTEGER.</p> <p>If <i>sqre</i> = 0: the lower block is an <i>nr</i>-by-<i>nr</i> square matrix.</p> <p>If <i>sqre</i> = 1: the lower block is an <i>nr</i>-by-(<i>nr</i>+1) rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + sqre$.</p>
<i>nrhs</i>	<p>INTEGER. The number of columns of <i>B</i> and <i>bx</i>.</p> <p>Must be at least 1.</p>
<i>b</i>	<p>REAL for slals0</p> <p>DOUBLE PRECISION for dlals0</p> <p>COMPLEX for clals0</p> <p>COMPLEX*16 for zlals0.</p> <p>Array, DIMENSION (<i>ldb</i>, <i>nrhs</i>).</p> <p>Contains the right hand sides of the least squares problem in rows 1 through <i>m</i>.</p>
<i>ldb</i>	<p>INTEGER. The leading dimension of <i>b</i>.</p> <p>Must be at least $\max(1, \max(m, n))$.</p>
<i>bx</i>	<p>REAL for slals0</p> <p>DOUBLE PRECISION for dlals0</p> <p>COMPLEX for clals0</p> <p>COMPLEX*16 for zlals0.</p> <p>Workspace array, DIMENSION (<i>ldb</i><i>x</i>, <i>nrhs</i>).</p>
<i>ldb</i> <i>x</i>	<p>INTEGER. The leading dimension of <i>bx</i>.</p>
<i>perm</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>).</p>

	The permutations (from deflation and sorting) applied to the two blocks.
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem.
<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i> , 2). Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.
<i>ldgcol</i>	INTEGER. The leading dimension of <i>givcol</i> , must be at least <i>n</i> .
<i>givnum</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>ldgnum</i> , 2). Each number indicates the <i>c</i> or <i>s</i> value used in the corresponding Givens rotation.
<i>ldgnum</i>	INTEGER. The leading dimension of arrays <i>difr</i> , <i>poles</i> and <i>givnum</i> , must be at least <i>k</i> .
<i>poles</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>ldgnum</i> , 2). On entry, <i>poles</i> (1: <i>k</i> , 1) contains the new singular values obtained from solving the secular equation, and <i>poles</i> (1: <i>k</i> , 2) is an array containing the poles in the secular equation.
<i>difl</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>k</i>). On entry, <i>difl</i> (<i>i</i>) is the distance between <i>i</i> -th updated (undeflated) singular value and the <i>i</i> -th (undeflated) old singular value.
<i>difr</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>ldgnum</i> , 2). On entry, <i>difr</i> (<i>i</i> , 1) contains the distances between <i>i</i> -th updated (undeflated) singular value and the <i>i+1</i> -th (undeflated) old singular value. And <i>difr</i> (<i>i</i> , 2) is the normalizing factor for the <i>i</i> -th right singular vector.
<i>z</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0

	Array, DIMENSION (k). Contains the components of the deflation-adjusted updating row vector.
K	INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.
c	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Contains garbage if $s_{qre} = 0$ and the c value of a Givens rotation related to the right null space if $s_{qre} = 1$.
s	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Contains garbage if $s_{qre} = 0$ and the s value of a Givens rotation related to the right null space if $s_{qre} = 1$.
$work$	REAL for slals0 DOUBLE PRECISION for dlals0 Workspace array, DIMENSION (k). Used with real flavors only.
$rwork$	REAL for clals0 DOUBLE PRECISION for zlals0 Workspace array, DIMENSION ($k*(1+nrhs) + 2*nrhs$). Used with complex flavors only.

Output Parameters

b	On exit, contains the solution x in rows 1 through n .
$info$	INTEGER. If $info = 0$: successful exit. If $info = -i < 0$, the i -th argument had an illegal value.

?lalsa

Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd.

Syntax

```
call slalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difl, difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info
)

call dlalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difl, difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info
)

call clalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difl, difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork,
info )

call zlalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difl, difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork,
info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine is an intermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form. The singular vectors are computed as products of simple orthogonal matrices.

If `icalmpq = 0`, ?lalsa applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if `icalmpq = 1`, the routine applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in the compact form by ?lalsa.

Input Parameters

<code>icalmpq</code>	INTEGER. Specifies whether the left or the right singular vector matrix is involved. If <code>icalmpq = 0</code> : left singular vector matrix is used If <code>icalmpq = 1</code> : right singular vector matrix is used.
----------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The row and column dimensions of the upper bidiagonal matrix.
<i>nrhs</i>	INTEGER. The number of columns of <i>b</i> and <i>bx</i> . Must be at least 1.
<i>b</i>	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa COMPLEX*16 for zlalsa Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). Contains the right hand sides of the least squares problem in rows 1 through <i>m</i> .
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, \max(m, n))$.
<i>ldbxx</i>	INTEGER. The leading dimension of the output array <i>bx</i> .
<i>u</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i>). On entry, <i>u</i> contains the left singular vector matrices of all subproblems at the bottom level.
<i>ldu</i>	INTEGER, $ldu \geq n$. The leading dimension of arrays <i>u</i> , <i>vt</i> , <i>difl</i> , <i>difr</i> , <i>poles</i> , <i>givnum</i> , and <i>z</i> .
<i>vt</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i> + 1). On entry, contains the right singular vector matrices of all subproblems at the bottom level.
<i>k</i>	INTEGER array, DIMENSION (<i>n</i>).
<i>difl</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>nlvl</i>), where $nlvl = \text{int}(\log_2(n / (smlsiz+1))) + 1$.
<i>difr</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa

	<p>Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>). On entry, <i>difl</i>(*, <i>i</i>) and <i>difr</i>(*, 2<i>i</i> -1) record distances between singular values on the <i>i</i>-th level and singular values on the (<i>i</i> -1)-th level, and <i>difr</i>(*, 2<i>i</i>) record the normalizing factors of the right singular vectors matrices of subproblems on <i>i</i>-th level.</p>
<i>z</i>	<p>REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i>, <i>nlvl</i>). On entry, <i>z</i>(1, <i>i</i>) contains the components of the deflation- adjusted updating the row vector for subproblems on the <i>i</i>-th level.</p>
<i>poles</i>	<p>REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>). On entry, <i>poles</i>(*, 2<i>i</i>-1: 2<i>i</i>) contains the new and old singular values involved in the secular equations on the <i>i</i>-th level.</p>
<i>givptr</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>). On entry, <i>givptr</i>(<i>i</i>) records the number of Givens rotations performed on the <i>i</i>-th problem on the computation tree.</p>
<i>givcol</i>	<p>INTEGER. Array, DIMENSION (<i>ldgcol</i>, 2*<i>nlvl</i>). On entry, for each <i>i</i>, <i>givcol</i>(*, 2<i>i</i>-1: 2<i>i</i>) records the locations of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>ldgcol</i>	<p>INTEGER, <i>ldgcol</i> ≥ <i>n</i>. The leading dimension of arrays <i>givcol</i> and <i>perm</i>.</p>
<i>perm</i>	<p>INTEGER. Array, DIMENSION (<i>ldgcol</i>, <i>nlvl</i>). On entry, <i>perm</i>(*, <i>i</i>) records permutations done on the <i>i</i>-th level of the computation tree.</p>
<i>givnum</i>	<p>REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>). On entry, <i>givnum</i>(*, 2<i>i</i>-1 : 2<i>i</i>) records the <i>c</i> and <i>s</i> values of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>c</i>	<p>REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa</p>

	Array, DIMENSION (n). On entry, if the i -th subproblem is not square, $c(i)$ contains the c value of a Givens rotation related to the right null space of the i -th subproblem.
s	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (n). On entry, if the i -th subproblem is not square, $s(i)$ contains the s -value of a Givens rotation related to the right null space of the i -th subproblem.
$work$	REAL for slalsa DOUBLE PRECISION for dlalsa Workspace array, DIMENSION at least (n). Used with real flavors only.
$rwork$	REAL for clalsa DOUBLE PRECISION for zlalsa Workspace array, DIMENSION at least $\max(n, (smlsz+1)*nrhs*3)$. Used with complex flavors only.
$iwork$	INTEGER. Workspace array, DIMENSION at least ($3n$).

Output Parameters

b	On exit, contains the solution x in rows 1 through n .
bx	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa COMPLEX*16 for zlalsa Array, DIMENSION ($ldbx, nrhs$). On exit, the result of applying the left or right singular vector matrix to b .
$info$	INTEGER. If $info = 0$: successful exit If $info = -i < 0$, the i -th argument had an illegal value.

slalsd

Uses the singular value decomposition of A to solve the least squares problem.

Syntax

```
call slalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork,
info )

call dlalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork,
info )

call clalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, rwork,
iwork, info )

call zlalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, rwork,
iwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine uses the singular value decomposition of A to solve the least squares problem of finding x to minimize the Euclidean norm of each column of A^*X-B , where A is n -by- n upper bidiagonal, and x and B are n -by- $nrhs$. The solution x overwrites B .

The singular values of A smaller than $rcond$ times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in d in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2.

It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Input Parameters

<code>uplo</code>	CHARACTER*1. If <code>uplo = 'U'</code> , d and e define an upper bidiagonal matrix. If <code>uplo = 'L'</code> , d and e define a lower bidiagonal matrix.
-------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The dimension of the bidiagonal matrix. $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of columns of <i>B</i> . Must be at least 1.
<i>d</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd Array, DIMENSION (<i>n</i> -1). Contains the super-diagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>b</i>	REAL for slalsd DOUBLE PRECISION for dlalsd COMPLEX for clalsd COMPLEX*16 for zlalsd Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). On input, <i>b</i> contains the right hand sides of the least squares problem. On output, <i>b</i> contains the solution X.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, n)$.
<i>rcond</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd The singular values of <i>A</i> less than or equal to <i>rcond</i> times the largest singular value are treated as zero in solving the least squares problem. If <i>rcond</i> is negative, machine precision is used instead. For example, for the least squares problem $\text{diag}(S) * X = B$, where $\text{diag}(S)$ is a diagonal matrix of singular values, the solution is $X(i) = B(i) / S(i)$ if $S(i)$ is greater than $rcond * \max(S)$, and $X(i) = 0$ if $S(i)$ is less than or equal to $rcond * \max(S)$.
<i>rank</i>	INTEGER. The number of singular values of <i>A</i> greater than <i>rcond</i> times the largest singular value.
<i>work</i>	REAL for slalsd DOUBLE PRECISION for dlalsd

	COMPLEX for clalsd COMPLEX*16 for zlalsd Workspace array. DIMENSION for real flavors at least $(9n+2n*smlsiz+8n*nlvl+n*nrhs+(smlsiz+1)^2)$, where $nlvl = \max(0, \text{int}(\log_2(n/(smlsiz+1))) + 1)$. DIMENSION for complex flavors is $(n*nrhs)$.
<i>rwork</i>	REAL for clalsd DOUBLE PRECISION for zlalsd Workspace array, used with complex flavors only. DIMENSION at least $(9n + 2n*smlsiz + 8n*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2)$, where $nlvl = \max(0, \text{int}(\log_2(\min(m,n)/(smlsiz+1))) + 1)$.
<i>iwork</i>	INTEGER. Workspace array of DIMENSION $(3n*nlvl + 11n)$.

Output Parameters

<i>d</i>	On exit, if <i>info</i> = 0, <i>d</i> contains singular values of the bidiagonal matrix.
<i>e</i>	On exit, destroyed.
<i>b</i>	On exit, <i>b</i> contains the solution <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit. If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns <i>info</i> /(<i>n</i> +1) through mod(<i>info</i> , <i>n</i> +1).

?lamrg

Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.

Syntax

```
call slamrg( n1, n2, a, strd1, strd2, index )
call dlamrg( n1, n2, a, strd1, strd2, index )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine creates a permutation list which will merge the elements of *a* (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

Input Parameters

<i>n1, n2</i>	INTEGER. These arguments contain the respective lengths of the two sorted lists to be merged.
<i>a</i>	REAL for <code>slamrg</code> DOUBLE PRECISION for <code>dlamrg</code> . Array, DIMENSION (<i>n1+n2</i>). The first <i>n1</i> elements of <i>a</i> contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final <i>n2</i> elements.
<i>strd1, strd2</i>	INTEGER. These are the strides to be taken through the array <i>a</i> . Allowable strides are 1 and -1. They indicate whether a subset of <i>a</i> is sorted in ascending (<i>strdx</i> = 1) or descending (<i>strdx</i> = -1) order.

Output Parameters

<i>index</i>	INTEGER. Array, DIMENSION (<i>n1+n2</i>). On exit, this array will contain a permutation such that if $b(i) = a(index(i))$ for $i=1, n1+n2$, then <i>b</i> will be sorted in ascending order.
--------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

?laneg

Computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal

$$T\text{-}\sigma * I = L * D * L^T.$$

Syntax

```
value = slaneg( n, d, lld, sigma, pivmin, r )
```

```
value = dlaneg( n, d, lld, sigma, pivmin, r )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal $T\text{-}\sigma * I = L * D * L^T$. This implementation works directly on the factors without forming the tridiagonal matrix T . The Sturm count is also the number of eigenvalues of T less than σ . This routine is called from `?larb`. The current routine does not use the `pivmin` parameter but rather requires IEEE-754 propagation of infinities and NaNs (NaN stands for 'Not A Number'). This routine also has no input range restrictions but does require default exception handling such that $x/0$ produces `Inf` when x is non-zero, and `Inf/Inf` produces NaN. (For more information see [Marques06]).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix.
<i>d</i>	REAL for <code>slaneg</code> DOUBLE PRECISION for <code>dlaneg</code> Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the matrix D .
<i>lld</i>	REAL for <code>slaneg</code> DOUBLE PRECISION for <code>dlaneg</code> Array, DIMENSION (<i>n</i> -1). Contains (<i>n</i> -1) elements $L(i) * L(i) * D(i)$.
<i>sigma</i>	REAL for <code>slaneg</code> DOUBLE PRECISION for <code>dlaneg</code> Shift amount in $T\text{-}\sigma * I = L * D * L^T$.
<i>pivmin</i>	REAL for <code>slaneg</code>

`DOUBLE PRECISION` for `dlaneg`
 The minimum pivot in the Sturm sequence. May be used when zero pivots are encountered on non-IEEE-754 architectures.

`r` `INTEGER`.
 The twist index for the twisted factorization that is used for the negcount.

Output Parameters

`value` `INTEGER`. The number of negative pivots encountered while factoring.

?langb

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.

Syntax

```
val = slangb( norm, n, kl, ku, ab, ldab, work )
val = dlangb( norm, n, kl, ku, ab, ldab, work )
val = clangb( norm, n, kl, ku, ab, ldab, work )
val = zlangb( norm, n, kl, ku, ab, ldab, work )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n band matrix A , with kl sub-diagonals and ku super-diagonals.

Input Parameters

`norm` `CHARACTER*1`. Specifies the value to be returned by the routine:

	<p>= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A.</p> <p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
n	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, <code>?langb</code> is set to zero.
kl	INTEGER. The number of sub-diagonals of the matrix A . $kl \geq 0$.
ku	INTEGER. The number of super-diagonals of the matrix A . $ku \geq 0$.
ab	<p>REAL for <code>slangb</code> DOUBLE PRECISION for <code>dlangb</code> COMPLEX for <code>clangb</code> COMPLEX*16 for <code>zlangb</code> Array, DIMENSION ($ldab, n$).</p> <p>The band matrix A, stored in rows 1 to $kl+ku+1$. The j-th column of A is stored in the j-th column of the array ab as follows:</p> <p>$ab(ku+1+i-j, j) = a(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.</p>
$ldab$	INTEGER. The leading dimension of the array ab . $ldab \geq kl+ku+1$.
$work$	<p>REAL for <code>slangb/clangb</code> DOUBLE PRECISION for <code>dlangb/zlangb</code> Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq n$ when $norm = 'I'$; otherwise, $work$ is not referenced.</p>

Output Parameters

val	REAL for <code>slangb/clangb</code>
-------	-------------------------------------

DOUBLE PRECISION for dlangb/zlangb
Value returned by the function.

?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Syntax

```
val = slange( norm, m, n, a, lda, work )
val = dlange( norm, m, n, a, lda, work )
val = clange( norm, m, n, a, lda, work )
val = zlange( norm, m, n, a, lda, work )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function `?lange` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix *A*.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i> . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> . $m \geq 0$. When $m = 0$, <code>?lange</code> is set to zero.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> .

$n \geq 0$. When $n = 0$, `?lange` is set to zero.

a REAL for `slange`
DOUBLE PRECISION for `dlange`
COMPLEX for `clange`
COMPLEX*16 for `zlange`
Array, DIMENSION (*lda*,*n*).
The *m*-by-*n* matrix *A*.

lda INTEGER. The leading dimension of the array *a*.
 $lda \geq \max(m, 1)$.

work REAL for `slange` and `clange`.
DOUBLE PRECISION for `dlange` and `zlange`.
Workspace array, DIMENSION $\max(1, lwork)$, where *lwork*
 $\geq m$ when *norm* = 'I'; otherwise, *work* is not referenced.

Output Parameters

val REAL for `slange/clange`
DOUBLE PRECISION for `dlange/zlange`
Value returned by the function.

?langt

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.

Syntax

```
val = slangt( norm, n, dl, d, du )
val = dlangt( norm, n, dl, d, du )
val = clangt( norm, n, dl, d, du )
val = zlangt( norm, n, dl, d, du )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex tridiagonal matrix A .

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

n INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, *?langt* is set to zero.

dl, d, du REAL for *slangt*
 DOUBLE PRECISION for *dlangt*
 COMPLEX for *clangt*
 COMPLEX*16 for *zlangt*
 Arrays: *dl* ($n-1$), *d* (n), *du* ($n-1$).
 The array *dl* contains the ($n-1$) sub-diagonal elements of A .
 The array *d* contains the diagonal elements of A .
 The array *du* contains the ($n-1$) super-diagonal elements of A .

Output Parameters

val REAL for *slangt/clangt*
 DOUBLE PRECISION for *dlangt/zlangt*
 Value returned by the function.

?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.

Syntax

```
val = slanhs( norm, n, a, lda, work )
val = dlanhs( norm, n, a, lda, work )
val = clanhs( norm, n, a, lda, work )
val = zlanhs( norm, n, a, lda, work )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The function `?lanhs` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix A .

The value `val` returned by the function is:

```
val = max(abs(Aij)), if norm = 'M' or 'm'
= norm1(A), if norm = '1' or 'O' or 'o'
= normI(A), if norm = 'I' or 'i'
= normF(A), if norm = 'F', 'f', 'E' or 'e'
```

where `norm1` denotes the 1-norm of a matrix (maximum column sum), `normI` denotes the infinity norm of a matrix (maximum row sum) and `normF` denotes the Frobenius norm of a matrix (square root of sum of squares). Note that `max(abs(Aij))` is not a consistent matrix norm.

Input Parameters

<code>norm</code>	CHARACTER*1. Specifies the value to be returned by the routine as described above.
<code>n</code>	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, <code>?lanhs</code> is set to zero.

a REAL for slanhb
 DOUBLE PRECISION for dlanhb
 COMPLEX for clanhb
 COMPLEX*16 for zlanhb
 Array, DIMENSION (*lda*,*n*). The *n*-by-*n* upper Hessenberg matrix *A*; the part of *A* below the first sub-diagonal is not referenced.

lda INTEGER. The leading dimension of the array *a*.
 $lda \geq \max(n, 1)$.

work REAL for slanhb and clanhb.
 DOUBLE PRECISION for dlanhb and zlanhb.
 Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq n$ when *norm* = 'I'; otherwise, *work* is not referenced.

Output Parameters

val REAL for slanhb/clanhb
 DOUBLE PRECISION for dlanhb/zlanhb
 Value returned by the function.

?lansb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.

Syntax

```
val = slansb( norm, uplo, n, k, ab, ldab, work )
val = dlansb( norm, uplo, n, k, ab, ldab, work )
val = clansb( norm, uplo, n, k, ab, ldab, work )
val = zlansb( norm, uplo, n, k, ab, ldab, work )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The function `?lansb` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n real/complex symmetric band matrix A , with k super-diagonals.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the band matrix A is supplied. If <i>uplo</i> = 'U': upper triangular part is supplied; If <i>uplo</i> = 'L': lower triangular part is supplied.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$.</p> <p>When $n = 0$, <code>?lansb</code> is set to zero.</p>
<i>k</i>	<p>INTEGER. The number of super-diagonals or sub-diagonals of the band matrix A. $k \geq 0$.</p>
<i>ab</i>	<p>REAL for <code>slansb</code> DOUBLE PRECISION for <code>dlansb</code> COMPLEX for <code>clansb</code> COMPLEX*16 for <code>zlansb</code></p> <p>Array, DIMENSION (<i>ldab</i>,<i>n</i>).</p> <p>The upper or lower triangle of the symmetric band matrix A, stored in the first $k+1$ rows of <i>ab</i>. The j-th column of A is stored in the j-th column of the array <i>ab</i> as follows:</p> <p>if <i>uplo</i> = 'U', $ab(k+1+i-j, j) = a(i, j)$</p> <p>for $\max(1, j-k) \leq i \leq j$;</p> <p>if <i>uplo</i> = 'L', $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$.</p>

ldab INTEGER. The leading dimension of the array *ab*.
 $ldab \geq k+1$.

work REAL for slansb and clansb.
 DOUBLE PRECISION for dlansb and zlansb.
 Workspace array, DIMENSION (max(1, *lwork*)), where
 $lwork \geq n$ when *norm* = 'I' or '1' or 'O'; otherwise,
work is not referenced.

Output Parameters

val REAL for slansb/clansb
 DOUBLE PRECISION for dlansb/zlansb
 Value returned by the function.

?lanhb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.

Syntax

```
val = clanhb( norm, uplo, n, k, ab, ldab, work )
```

```
val = zlanhb( norm, uplo, n, k, ab, ldab, work )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n Hermitian band matrix A , with k super-diagonals.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .

	<p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the band matrix A is supplied.</p> <p>If <i>uplo</i> = 'U': upper triangular part is supplied;</p> <p>If <i>uplo</i> = 'L': lower triangular part is supplied.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <i>?lanhb</i> is set to zero.</p>
<i>k</i>	<p>INTEGER. The number of super-diagonals or sub-diagonals of the band matrix A.</p> <p>$k \geq 0$.</p>
<i>ab</i>	<p>COMPLEX for <i>clanhb</i>.</p> <p>COMPLEX*16 for <i>zlanhb</i>.</p> <p>Array, DIMENSION (<i>ldaB</i>,<i>n</i>). The upper or lower triangle of the Hermitian band matrix A, stored in the first $k+1$ rows of <i>ab</i>. The j-th column of A is stored in the j-th column of the array <i>ab</i> as follows:</p> <p>if <i>uplo</i> = 'U', $ab(k+1+i-j, j) = a(i, j)$</p> <p>for $\max(1, j-k) \leq i \leq j$;</p> <p>if <i>uplo</i> = 'L', $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$.</p> <p>Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.</p>
<i>ldab</i>	<p>INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq k+1$.</p>
<i>work</i>	<p>REAL for <i>clanhb</i>.</p> <p>DOUBLE PRECISION for <i>zlanhb</i>.</p> <p>Workspace array, DIMENSION $\max(1, lwork)$, where $lwork \geq n$ when <i>norm</i> = 'I' or '1' or 'O'; otherwise, <i>work</i> is not referenced.</p>

Output Parameters

`val` REAL for `slanhb/clanhb`
 DOUBLE PRECISION for `dlanhb/zlanhb`
 Value returned by the function.

?lansp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.

Syntax

```
val = slansp( norm, uplo, n, ap, work )
val = dlansp( norm, uplo, n, ap, work )
val = clansp( norm, uplo, n, ap, work )
val = zlanasp( norm, uplo, n, ap, work )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function `?lanasp` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix `A`, supplied in packed form.

Input Parameters

`norm` CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix `A`.
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix `A` (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix `A` (maximum row sum),

`= 'F', 'f', 'E' or 'e':` `val = normF(A)`, Frobenius norm of the matrix `A` (square root of sum of squares).

`uplo` CHARACTER*1.
Specifies whether the upper or lower triangular part of the symmetric matrix `A` is supplied.
If `uplo = 'U'`: Upper triangular part of `A` is supplied
If `uplo = 'L'`: Lower triangular part of `A` is supplied.

`n` INTEGER. The order of the matrix `A`. $n \geq 0$. When $n = 0$, `?lansp` is set to zero.

`ap` REAL for `slansp`
DOUBLE PRECISION for `dlansp`
COMPLEX for `clansp`
COMPLEX*16 for `zlansp`
Array, DIMENSION $(n(n+1)/2)$.
The upper or lower triangle of the symmetric matrix `A`, packed columnwise in a linear array. The j -th column of `A` is stored in the array `ap` as follows:
if `uplo = 'U'`, $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;
if `uplo = 'L'`, $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

`work` REAL for `slansp` and `clansp`.
DOUBLE PRECISION for `dlansp` and `zlansp`.
Workspace array, DIMENSION $(\max(1, lwork))$, where $lwork \geq n$ when `norm = 'I' or '1' or 'O'`; otherwise, `work` is not referenced.

Output Parameters

`val` REAL for `slansp/clansp`
DOUBLE PRECISION for `dlansp/zlansp`
Value returned by the function.

?lanhp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.

Syntax

```
val = clanhp( norm, uplo, n, ap, work )
val = zlanhp( norm, uplo, n, ap, work )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function `?lanhp` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix *A*, supplied in packed form.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is supplied.</p> <p>If <i>uplo</i> = 'U': Upper triangular part of <i>A</i> is supplied</p> <p>If <i>uplo</i> = 'L': Lower triangular part of <i>A</i> is supplied.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>.</p> <p>$n \geq 0$. When $n = 0$, <code>?lanhp</code> is set to zero.</p>

ap COMPLEX for `clanhp`.
 COMPLEX*16 for `zlanhp`.
 Array, DIMENSION $(n(n+1)/2)$. The upper or lower triangle of the Hermitian matrix *A*, packed columnwise in a linear array. The *j*-th column of *A* is stored in the array *ap* as follows:
 if *uplo* = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;
 if *uplo* = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

work REAL for `clanhp`.
 DOUBLE PRECISION for `zlanhp`.
 Workspace array, DIMENSION $(\max(1, lwork))$, where $lwork \geq n$ when *norm* = 'I' or '1' or 'O'; otherwise, *work* is not referenced.

Output Parameters

val REAL for `clanhp`.
 DOUBLE PRECISION for `zlanhp`.
 Value returned by the function.

?lanst/?lanht

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.

Syntax

```
val = slanst( norm, n, d, e )
val = dlanst( norm, n, d, e )
val = clanht( norm, n, d, e )
val = zlanht( norm, n, d, e )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The functions `?lanst/?lanht` return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or a complex Hermitian tridiagonal matrix A .

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij})),$ largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A),$ 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A),$ infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A),$ Frobenius norm of the matrix A (square root of sum of squares).
<i>n</i>	<p>INTEGER. The order of the matrix A.</p> <p>$n \geq 0$. When $n = 0$, <code>?lanst/?lanht</code> is set to zero.</p>
<i>d</i>	<p>REAL for <code>slanst/clanht</code> DOUBLE PRECISION for <code>dlanst/zlanht</code> Array, DIMENSION (n). The diagonal elements of A.</p>
<i>e</i>	<p>REAL for <code>slanst</code> DOUBLE PRECISION for <code>dlanst</code> COMPLEX for <code>clanht</code> COMPLEX*16 for <code>zlanht</code> Array, DIMENSION ($n-1$). The ($n-1$) sub-diagonal or super-diagonal elements of A.</p>

Output Parameters

<i>val</i>	<p>REAL for <code>slanst/clanht</code> DOUBLE PRECISION for <code>dlanst/zlanht</code> Value returned by the function.</p>
------------	--------------------------------------------------------------------------------------------------------------------------------------

?lansy

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

Syntax

```
val = slansy( norm, uplo, n, a, lda, work )
val = dlansy( norm, uplo, n, a, lda, work )
val = clansy( norm, uplo, n, a, lda, work )
val = zlansy( norm, uplo, n, a, lda, work )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The function `?lansy` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix `A`.

Input Parameters

<code>norm</code>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <code>A</code>. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <code>A</code> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <code>A</code> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <code>A</code> (square root of sum of squares).
<code>uplo</code>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the symmetric matrix <code>A</code> is to be referenced.</p> <ul style="list-style-type: none"> = 'U': Upper triangular part of <code>A</code> is referenced. = 'L': Lower triangular part of <code>A</code> is referenced

n INTEGER. The order of the matrix *A*. $n \geq 0$. When $n = 0$, `?lansy` is set to zero.

a REAL for `slansy`
 DOUBLE PRECISION for `dlansy`
 COMPLEX for `clansy`
 COMPLEX*16 for `zlansy`
 Array, DIMENSION (*lda*,*n*). The symmetric matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*.
 $lda \geq \max(n,1)$.

work REAL for `slansy` and `clansy`.
 DOUBLE PRECISION for `dlansy` and `zlansy`.
 Workspace array, DIMENSION ($\max(1, lwork)$), where
 $lwork \geq n$ when *norm* = 'I' or '1' or 'O'; otherwise,
work is not referenced.

Output Parameters

val REAL for `slansy/clansy`
 DOUBLE PRECISION for `dlansy/zlansy`
 Value returned by the function.

?lanhe

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.

Syntax

```
val = clanhe( norm, uplo, n, a, lda, work )
val = zlanhe( norm, uplo, n, a, lda, work )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The function `?lanhe` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix *A*.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is to be referenced.</p> <ul style="list-style-type: none"> = 'U': Upper triangular part of <i>A</i> is referenced. = 'L': Lower triangular part of <i>A</i> is referenced
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>. $n \geq 0$. When $n = 0$, <code>?lanhe</code> is set to zero.</p>
<i>a</i>	<p>COMPLEX for <code>clanhe</code>. COMPLEX*16 for <code>zlanhe</code>.</p> <p>Array, DIMENSION (<i>lda</i>,<i>n</i>). The Hermitian matrix <i>A</i>. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i>, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i>, and the strictly upper triangular part of <i>a</i> is not referenced.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>.</p> <p>$lda \geq \max(n, 1)$.</p>

work REAL for `clanhe`.
 DOUBLE PRECISION for `zlanhe`.
 Workspace array, DIMENSION $(\max(1, lwork))$, where
 $lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise,
work is not referenced.

Output Parameters

val REAL for `clanhe`.
 DOUBLE PRECISION for `zlanhe`.
 Value returned by the function.

?lantb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.

Syntax

```
val = slantb( norm, uplo, diag, n, k, ab, ldab, work )
val = dlantb( norm, uplo, diag, n, k, ab, ldab, work )
val = clantb( norm, uplo, diag, n, k, ab, ldab, work )
val = zlantb( norm, uplo, diag, n, k, ab, ldab, work )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The function `?lantb` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n triangular band matrix A , with $(k + 1)$ diagonals.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .

	<p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the matrix A is upper or lower triangular.</p> <p>= 'U': Upper triangular</p> <p>= 'L': Lower triangular.</p>
<i>diag</i>	<p>CHARACTER*1.</p> <p>Specifies whether or not the matrix A is unit triangular.</p> <p>= 'N': Non-unit triangular</p> <p>= 'U': Unit triangular.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, ?lantb is set to zero.</p>
<i>k</i>	<p>INTEGER. The number of super-diagonals of the matrix A if $uplo = 'U'$, or the number of sub-diagonals of the matrix A if $uplo = 'L'$. $k \geq 0$.</p>
<i>ab</i>	<p>REAL for slantb</p> <p>DOUBLE PRECISION for dlantb</p> <p>COMPLEX for clantb</p> <p>COMPLEX*16 for zlantb</p> <p>Array, DIMENSION ($ldab, n$). The upper or lower triangular band matrix A, stored in the first $k+1$ rows of ab. The j-th column of A is stored in the j-th column of the array ab as follows:</p> <p>if $uplo = 'U'$, $ab(k+1+i-j, j) = a(i, j)$ for $\max(1, j-k) \leq i \leq j$;</p> <p>if $uplo = 'L'$, $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$.</p> <p>Note that when $diag = 'U'$, the elements of the array ab corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.</p>
<i>ldab</i>	<p>INTEGER. The leading dimension of the array ab.</p>

ldab $\geq k+1$.

work REAL for slantb and clantb.
 DOUBLE PRECISION for dlantb and zlantb.
 Workspace array, DIMENSION (max(1,*lwork*)), where
lwork $\geq n$ when *norm* = 'I' ; otherwise, *work* is not
 referenced.

Output Parameters

val REAL for slantb/clantb.
 DOUBLE PRECISION for dlantb/zlantb.
 Value returned by the function.

?lantp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.

Syntax

```
val = slantp( norm, uplo, diag, n, ap, work )
val = dlantp( norm, uplo, diag, n, ap, work )
val = clantp( norm, uplo, diag, n, ap, work )
val = zlantp( norm, uplo, diag, n, ap, work )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function ?lantp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix *A*, supplied in packed form.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

uplo CHARACTER*1.
 Specifies whether the matrix A is upper or lower triangular.
 = 'U': Upper triangular
 = 'L': Lower triangular.

diag CHARACTER*1.
 Specifies whether or not the matrix A is unit triangular.
 = 'N': Non-unit triangular
 = 'U': Unit triangular.

n INTEGER. The order of the matrix A .
 $n \geq 0$. When $n = 0$, *?lantp* is set to zero.

ap REAL for slantp
 DOUBLE PRECISION for dlantp
 COMPLEX for clantp
 COMPLEX*16 for zlantp
 Array, DIMENSION $(n(n+1)/2)$.
 The upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array *ap* as follows:
 if *uplo* = 'U', $ap(i + (j-1)j/2) = a(i, j)$ for $1 \leq i \leq j$;
 if *uplo* = 'L', $ap(i + (j-1)(2n-j)/2) = a(i, j)$ for $j \leq i \leq n$.
 Note that when *diag* = 'U', the elements of the array *ap* corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

work REAL for slantp and clantp.
 DOUBLE PRECISION for dlantp and zlantp.

Workspace array, `DIMENSION (max(1,lwork))`, where $lwork \geq n$ when `norm = 'I'`; otherwise, `work` is not referenced.

Output Parameters

`val` REAL for `slantr/clantr`.
DOUBLE PRECISION for `dlantr/zlantr`.
Value returned by the function.

?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.

Syntax

```
val = slantr( norm, uplo, diag, m, n, a, lda, work )
val = dlantr( norm, uplo, diag, m, n, a, lda, work )
val = clantr( norm, uplo, diag, m, n, a, lda, work )
val = zlantr( norm, uplo, diag, m, n, a, lda, work )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function `?lantr` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix `A`.

Input Parameters

`norm` CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix `A`.
= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix `A` (maximum column sum),

	<p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the matrix A is upper or lower trapezoidal.</p> <p>= 'U': Upper trapezoidal</p> <p>= 'L': Lower trapezoidal.</p> <p>Note that A is triangular instead of trapezoidal if $m = n$.</p>
<i>diag</i>	<p>CHARACTER*1.</p> <p>Specifies whether or not the matrix A has unit diagonal.</p> <p>= 'N': Non-unit diagonal</p> <p>= 'U': Unit diagonal.</p>
<i>m</i>	<p>INTEGER. The number of rows of the matrix A. $m \geq 0$, and</p> <p>if <i>uplo</i> = 'U', $m \leq n$.</p> <p>When $m = 0$, ?lantr is set to zero.</p>
<i>n</i>	<p>INTEGER. The number of columns of the matrix A. $n \geq 0$,</p> <p>and if <i>uplo</i> = 'L', $n \leq m$.</p> <p>When $n = 0$, ?lantr is set to zero.</p>
<i>a</i>	<p>REAL for slantr</p> <p>DOUBLE PRECISION for dlantr</p> <p>COMPLEX for clantr</p> <p>COMPLEX*16 for zlantr</p> <p>Array, DIMENSION (<i>lda</i>,<i>n</i>).</p> <p>The trapezoidal matrix A (A is triangular if $m = n$).</p> <p>If <i>uplo</i> = 'U', the leading m-by-n upper trapezoidal part of the array <i>a</i> contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading m-by-n lower trapezoidal part of the array <i>a</i> contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when <i>diag</i> = 'U', the diagonal elements of A are not referenced and are assumed to be one.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>.</p> <p>$lda \geq \max(m, 1)$.</p>

work REAL for slantr/clantrp.
 DOUBLE PRECISION for dlantr/zlantr.
 Workspace array, DIMENSION (max(1,*lwork*)), where
lwork ≥ *m* when *norm* = 'I' ; otherwise, *work* is not
 referenced.

Output Parameters

val REAL for slantr/clantrp.
 DOUBLE PRECISION for dlantr/zlantr.
 Value returned by the function.

?lanv2

*Computes the Schur factorization of a real 2-by-2
 nonsymmetric matrix in standard form.*

Syntax

```
call slanv2( a, b, c, d, rtlr, rtli, rt2r, rt2i, cs, sn )
call dlanv2( a, b, c, d, rtlr, rtli, rt2r, rt2i, cs, sn )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} cs & -sn \\ sn & cs \end{bmatrix} \begin{bmatrix} aa & bb \\ cc & dd \end{bmatrix} \begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix}$$

where either

1. *cc* = 0 so that *aa* and *dd* are real eigenvalues of the matrix, or
2. *aa* = *dd* and *bb*cc* < 0, so that $aa \pm \sqrt{bb*cc}$ are complex conjugate eigenvalues.

The routine was adjusted to reduce the risk of cancellation errors, when computing real eigenvalues, and to ensure, if possible, that $\text{abs}(rt1r) \geq \text{abs}(rt2r)$.

Input Parameters

a, b, c, d REAL for slanv2
DOUBLE PRECISION for dlanv2.
On entry, elements of the input matrix.

Output Parameters

a, b, c, d On exit, overwritten by the elements of the standardized Schur form.

$rt1r, rt1i, rt2r, rt2i$ REAL for slanv2
DOUBLE PRECISION for dlanv2.
The real and imaginary parts of the eigenvalues.
If the eigenvalues are a complex conjugate pair, $rt1i > 0$.

cs, sn REAL for slanv2
DOUBLE PRECISION for dlanv2.
Parameters of the rotation matrix.

?lapll

Measures the linear dependence of two vectors.

Syntax

```
call slapll( n, x, incx, Y, incy, ssmin )
call dlapll( n, x, incx, Y, incy, ssmin )
call clapll( n, x, incx, Y, incy, ssmin )
call zlapll( n, x, incx, Y, incy, ssmin )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

Given two column vectors x and y of length n , let

$A = \begin{pmatrix} x & y \end{pmatrix}$ be the n -by-2 matrix.

The routine `?lap11` first computes the QR factorization of A as $A = Q^*R$ and then computes the SVD of the 2-by-2 upper triangular matrix R . The smaller singular value of R is returned in $ssmin$, which is used as the measurement of the linear dependency of the vectors x and y .

Input Parameters

n	INTEGER. The length of the vectors x and y .
x	REAL for <code>slap11</code> DOUBLE PRECISION for <code>dlap11</code> COMPLEX for <code>clap11</code> COMPLEX*16 for <code>zlap11</code> Array, DIMENSION $(1+(n-1)incx)$. On entry, x contains the n -vector x .
y	REAL for <code>slap11</code> DOUBLE PRECISION for <code>dlap11</code> COMPLEX for <code>clap11</code> COMPLEX*16 for <code>zlap11</code> Array, DIMENSION $(1+(n-1)incy)$. On entry, y contains the n -vector y .
$incx$	INTEGER. The increment between successive elements of x ; $incx > 0$.
$incy$	INTEGER. The increment between successive elements of y ; $incy > 0$.

Output Parameters

x	On exit, x is overwritten.
y	On exit, y is overwritten.
$ssmin$	REAL for <code>slap11/clap11</code> DOUBLE PRECISION for <code>dlap11/zlap11</code> The smallest singular value of the n -by-2 matrix $A = \begin{pmatrix} x & y \end{pmatrix}$.

?lapmt

Performs a forward or backward permutation of the columns of a matrix.

Syntax

```
call slapmt( forwrd, m, n, x, ldx, k )
call dlapmt( forwrd, m, n, x, ldx, k )
call clapmt( forwrd, m, n, x, ldx, k )
call zlapmt( forwrd, m, n, x, ldx, k )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lapmt rearranges the columns of the m -by- n matrix X as specified by the permutation $k(1), k(2), \dots, k(n)$ of the integers $1, \dots, n$.

If `forwrd = .TRUE.`, forward permutation:

$X(*, k(j))$ is moved to $X(*, j)$ for $j=1, 2, \dots, n$.

If `forwrd = .FALSE.`, backward permutation:

$X(*, j)$ is moved to $X(*, k(j))$ for $j = 1, 2, \dots, n$.

Input Parameters

<code>forwrd</code>	LOGICAL. If <code>forwrd = .TRUE.</code> , forward permutation If <code>forwrd = .FALSE.</code> , backward permutation
<code>m</code>	INTEGER. The number of rows of the matrix X . $m \geq 0$.
<code>n</code>	INTEGER. The number of columns of the matrix X . $n \geq 0$.
<code>x</code>	REAL for slapmt DOUBLE PRECISION for dlapmt COMPLEX for clapmt COMPLEX*16 for zlapmt Array, DIMENSION (<code>ldx</code> , <code>n</code>). On entry, the m -by- n matrix X .

ldx INTEGER. The leading dimension of the array *X*, $ldx \geq \max(1, m)$.

k INTEGER. Array, DIMENSION (*n*). On entry, *k* contains the permutation vector and is used as internal workspace.

Output Parameters

x On exit, *x* contains the permuted matrix *X*.

k On exit, *k* is reset to its original value.

?lapy2

Returns $\sqrt{x^2 + y^2}$.

Syntax

`val = slapy2(x, y)`

`val = dlapy2(x, y)`

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The function ?lapy2 returns $\sqrt{x^2 + y^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

x, y REAL for `slapy2`
DOUBLE PRECISION for `dlapy2`
Specify the input values *x* and *y*.

Output Parameters

val REAL for `slapy2`
DOUBLE PRECISION for `dlapy2`.
Value returned by the function.

?lapy3

Returns $\sqrt{x^2+y^2+z^2}$.

Syntax

```
val = slapy3( x, y, z )
```

```
val = dlapy3( x, y, z )
```

Description

This function is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The function `?lapy3` returns $\sqrt{x^2+y^2+z^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

x, y, z	REAL for <code>slapy3</code> DOUBLE PRECISION for <code>dlapy3</code> Specify the input values x, y and z .
-----------	-----------------------------------------------------------------------------------------------------------------------

Output Parameters

val	REAL for <code>slapy3</code> DOUBLE PRECISION for <code>dlapy3</code> . Value returned by the function.
-------	---------------------------------------------------------------------------------------------------------------

?laqgb

Scales a general band matrix, using row and column scaling factors computed by ?gbequ.

Syntax

```
call slaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
```

```
call dlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
```

```
call claqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
```

```
call zlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine equilibrates a general m -by- n band matrix A with kl subdiagonals and ku superdiagonals using the row and column scaling factors in the vectors r and c .

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A . $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A . $ku \geq 0$.
ab	REAL for <code>slaqgb</code> DOUBLE PRECISION for <code>dlaqgb</code> COMPLEX for <code>claqgb</code> COMPLEX*16 for <code>zlaqgb</code> Array, DIMENSION ($ldab, n$). On entry, the matrix A in band storage, in rows 1 to $kl+ku+1$. The j -th column of A is stored in the j -th column of the array ab as follows: $ab(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.
$ldab$	INTEGER. The leading dimension of the array ab . $lda \geq kl+ku+1$.
$amax$	REAL for <code>slaqgb/claqgb</code> DOUBLE PRECISION for <code>dlaqgb/zlaqgb</code> Absolute value of largest matrix entry.
r, c	REAL for <code>slaqgb/claqgb</code> DOUBLE PRECISION for <code>dlaqgb/zlaqgb</code> Arrays $r(m)$, $c(n)$. Contain the row and column scale factors for A , respectively.
$rowcnd$	REAL for <code>slaqgb/claqgb</code> DOUBLE PRECISION for <code>dlaqgb/zlaqgb</code>

colcnd Ratio of the smallest $r(i)$ to the largest $r(i)$.
 REAL for `slaggb/claggb`
 DOUBLE PRECISION for `dlaqgb/zlaqgb`
 Ratio of the smallest $c(i)$ to the largest $c(i)$.

Output Parameters

ab On exit, the equilibrated matrix, in the same storage format as *A*.
 See *equed* for the form of the equilibrated matrix.

equed CHARACTER*1.
 Specifies the form of equilibration that was done.
 If *equed* = 'N': No equilibration
 If *equed* = 'R': Row equilibration, that is, *A* has been premultiplied by $\text{diag}(r)$.
 If *equed* = 'C': Column equilibration, that is, *A* has been postmultiplied by $\text{diag}(c)$.
 If *equed* = 'B': Both row and column equilibration, that is, *A* has been replaced by $\text{diag}(r) * A * \text{diag}(c)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If $\text{rowcnd} < \text{thresh}$, row scaling is done, and if $\text{colcnd} < \text{thresh}$, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If $\text{amax} > \text{large}$ or $\text{amax} < \text{small}$, row scaling is done.

?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ.

Syntax

```
call slaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call dlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call claqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call zlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine equilibrates a general m -by- n matrix A using the row and column scaling factors in the vectors r and c .

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
a	REAL for slaqge DOUBLE PRECISION for dlaqge COMPLEX for claqge COMPLEX*16 for zlaqge Array, DIMENSION (lda, n). On entry, the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(m, 1)$.
r	REAL for slangge/claqge DOUBLE PRECISION for dlaqge/zlaqge Array, DIMENSION (m). The row scale factors for A .
c	REAL for slangge/claqge

	DOUBLE PRECISION for dlaqge/zlaqge Array, DIMENSION (<i>n</i>). The column scale factors for A.
<i>rowcnd</i>	REAL for slangge/claqge DOUBLE PRECISION for dlaqge/zlaqge Ratio of the smallest $r(i)$ to the largest $r(i)$.
<i>colcnd</i>	REAL for slangge/claqge DOUBLE PRECISION for dlaqge/zlaqge Ratio of the smallest $c(i)$ to the largest $c(i)$.
<i>amax</i>	REAL for slangge/claqge DOUBLE PRECISION for dlaqge/zlaqge Absolute value of largest matrix entry.

Output Parameters

<i>a</i>	On exit, the equilibrated matrix. See <i>equed</i> for the form of the equilibrated matrix.
<i>equed</i>	CHARACTER*1. Specifies the form of equilibration that was done. If <i>equed</i> = 'N': No equilibration If <i>equed</i> = 'R': Row equilibration, that is, A has been premultiplied by $\text{diag}(r)$. If <i>equed</i> = 'C': Column equilibration, that is, A has been postmultiplied by $\text{diag}(c)$. If <i>equed</i> = 'B': Both row and column equilibration, that is, A has been replaced by $\text{diag}(r) * A * \text{diag}(c)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If $\text{rowcnd} < \text{thresh}$, row scaling is done, and if $\text{colcnd} < \text{thresh}$, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If $\text{amax} > \text{large}$ or $\text{amax} < \text{small}$, row scaling is done.

zlaqhb

Scales a Hermetian band matrix, using scaling factors computed by zpbeku.

Syntax

```
call claqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

```
call zlaqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine equilibrates a Hermetian band matrix A using the scaling factors in the vector s .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix A is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix A if <i>uplo</i> = 'U', or the number of sub-diagonals if <i>uplo</i> = 'L'. $kd \geq 0$.
<i>ab</i>	COMPLEX for <code>claqhb</code> COMPLEX*16 for <code>zlaqhb</code> Array, DIMENSION (<i>ldab</i> , <i>n</i>). On entry, the upper or lower triangle of the band matrix A , stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$;

if *uplo* = 'L', $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

ldab INTEGER. The leading dimension of the array *ab*.
 $ldab \geq kd+1$.

scond REAL for *claqs*b
 DOUBLE PRECISION for *zlaqs*b
 Ratio of the smallest $s(i)$ to the largest $s(i)$.

amax REAL for *claqs*b
 DOUBLE PRECISION for *zlaqs*b
 Absolute value of largest matrix entry.

Output Parameters

ab On exit, if *info* = 0, the triangular factor *U* or *L* from the Cholesky factorization $A = U' * U$ or $A = L * L'$ of the band matrix *A*, in the same storage format as *A*.

s REAL for *claqs*b
 DOUBLE PRECISION for *zlaqs*b
 Array, DIMENSION (*n*). The scale factors for *A*.

equed CHARACTER*1.
 Specifies whether or not equilibration was done.
 If *equed* = 'N': No equilibration.
 If *equed* = 'Y': Equilibration was done, that is, *A* has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < thresh$, scaling is done.

The values *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > large$ or $amax < small$, scaling is done.

?laqp2

Computes a QR factorization with column pivoting of the matrix block.

Syntax

```
call slaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call dlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call claqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call zlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes a QR factorization with column pivoting of the block $A(offset+1:m, 1:n)$. The block $A(1:offset, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> . $n \geq 0$.
<i>offset</i>	INTEGER. The number of rows of the matrix <i>A</i> that must be pivoted but no factorized. $offset \geq 0$.
<i>a</i>	REAL for slaqp2 DOUBLE PRECISION for dlaqp2 COMPLEX for claqp2 COMPLEX*16 for zlaqp2 Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.
<i>jpvt</i>	INTEGER. Array, DIMENSION (<i>n</i>).

On entry, if $jpvt(i) \neq 0$, the i -th column of A is permuted to the front of A^*P (a leading column); if $jpvt(i) = 0$, the i -th column of A is a free column.

vn1, vn2

REAL for slaqp2/claqp2

DOUBLE PRECISION for dlaqp2/zlaqp2

Arrays, DIMENSION (n) each. Contain the vectors with the partial and exact column norms, respectively.

work

REAL for slaqp2

DOUBLE PRECISION for dlaqp2

COMPLEX for claqp2

COMPLEX*16 for zlaqp2 Workspace array, DIMENSION (n).

Output Parameters

a

On exit, the upper triangle of block $A(offset+1:m, 1:n)$ is the triangular factor obtained; the elements in block $A(offset+1:m, 1:n)$ below the diagonal, together with the array *tau*, represent the orthogonal matrix Q as a product of elementary reflectors. Block $A(1:offset, 1:n)$ has been accordingly pivoted, but not factorized.

jpvt

On exit, if $jpvt(i) = k$, then the i -th column of A^*P was the k -th column of A .

tau

REAL for slaqp2

DOUBLE PRECISION for dlaqp2

COMPLEX for claqp2

COMPLEX*16 for zlaqp2

Array, DIMENSION ($\min(m, n)$).

The scalar factors of the elementary reflectors.

vn1, vn2

Contain the vectors with the partial and exact column norms, respectively.

?laqps

Computes a step of QR factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3.

Syntax

```
call slaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
call dlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
call claqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
call zlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes a step of *QR* factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3. The routine tries to factorize NB columns from A starting from the row $offset+1$, and updates all of the matrix with BLAS level 3 routine ?gemm.

In some cases, due to catastrophic cancellations, ?laqps cannot factorize NB columns. Hence, the actual number of factorized columns is returned in kb .

Block $A(1:offset, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
$offset$	INTEGER. The number of rows of A that have been factorized in previous steps.
nb	INTEGER. The number of columns to factorize.
a	REAL for slaqps

	DOUBLE PRECISION for dlaqps COMPLEX for claqp COMPLEX*16 for zlaqp Array, DIMENSION (lda, n). On entry, the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(1, m)$.
$jpvt$	INTEGER. Array, DIMENSION (n). If $jpvt(i) = k$ then column k of the full matrix A has been permuted into position i in AP.
$vn1, vn2$	REAL for slaqp/claqp DOUBLE PRECISION for dlaqp/zlaqp Arrays, DIMENSION (n) each. Contain the vectors with the partial and exact column norms, respectively.
$auxv$	REAL for slaqp DOUBLE PRECISION for dlaqp COMPLEX for claqp COMPLEX*16 for zlaqp Array, DIMENSION (nb). Auxiliary vector.
f	REAL for slaqp DOUBLE PRECISION for dlaqp COMPLEX for claqp COMPLEX*16 for zlaqp Array, DIMENSION (ldf, nb). Matrix $F' = L^*Y'^*A$.
ldf	INTEGER. The leading dimension of the array f . $ldf \geq \max(1, n)$.

Output Parameters

kb	INTEGER. The number of columns actually factorized.
a	On exit, block $A(offset+1:m, 1:kb)$ is the triangular factor obtained and block $A(1:offset, 1:n)$ has been accordingly pivoted, but no factorized. The rest of the matrix, block $A(offset+1:m, kb+1:n)$ has been updated.

<i>jpvt</i>	INTEGER array, DIMENSION (<i>n</i>). If <i>jpvt</i> (<i>i</i>) = <i>k</i> then column <i>k</i> of the full matrix <i>A</i> has been permuted into position <i>i</i> in AP.
<i>tau</i>	REAL for slaqps DOUBLE PRECISION for dlaqps COMPLEX for claqps COMPLEX*16 for zlaqps Array, DIMENSION (<i>kb</i>). The scalar factors of the elementary reflectors.
<i>vn1, vn2</i>	The vectors with the partial and exact column norms, respectively.
<i>auxv</i>	Auxiliary vector.
<i>f</i>	Matrix $F' = L^*Y'^*A$.

?laqr0

Computes the eigenvalues of a Hessenberg matrix, and optionally the marixes from the Schur decomposition.

Syntax

```
call slaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )

call dlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )

call claqz0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )

call zlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z^* T^* Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q^* H^* Q^H = (QZ)^* H^* (QZ)^H$.

Input Parameters

<i>wantt</i>	LOGICAL. If <i>wantt</i> = .TRUE., the full Schur form T is required; If <i>wantt</i> = .FALSE., only eigenvalues are required.
<i>wantz</i>	LOGICAL. If <i>wantz</i> = .TRUE., the matrix of Schur vectors Z is required; If <i>wantz</i> = .FALSE., Schur vectors are not required.
<i>n</i>	INTEGER. The order of the Hessenberg matrix H . ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. It is assumed that H is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$, and if $ilo > 1$ then $H(ilo, ilo-1) = 0$. <i>ilo</i> and <i>ihi</i> are normally set by a previous call to <code>cgebal</code> , and then passed to <code>cgehrd</code> when the matrix output by <code>cgebal</code> is reduced to Hessenberg form. Otherwise, <i>ilo</i> and <i>ihi</i> should be set to 1 and n , respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n=0$, then $ilo=1$ and $ihi=0$
<i>h</i>	REAL for <code>slaqr0</code> DOUBLE PRECISION for <code>dlaqr0</code> COMPLEX for <code>claqr0</code> COMPLEX*16 for <code>zlaqr0</code> . Array, DIMENSION (<i>ldh</i> , n), contains the upper Hessenberg matrix H .
<i>ldh</i>	INTEGER. The leading dimension of the array h . $ldh \geq \max(1, n)$.

<i>iloz, ihiz</i>	<p>INTEGER. Specify the rows of z to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code>, $1 \leq iloz \leq ilo$; $ihl \leq ihiz \leq n$.</p>
<i>z</i>	<p>REAL for <code>slaqr0</code> DOUBLE PRECISION for <code>dlaqr0</code> COMPLEX for <code>claqr0</code> COMPLEX*16 for <code>zlaqr0</code>. Array, DIMENSION (<i>ldz</i>, <i>ihl</i>), contains the matrix z if <i>wantz</i> is <code>.TRUE.</code>. If <i>wantz</i> is <code>.FALSE.</code>, z is not referenced.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the array z. If <i>wantz</i> is <code>.TRUE.</code>, then $ldz \geq \max(1, ihiz)$. Otherwise, $ldz \geq 1$.</p>
<i>work</i>	<p>REAL for <code>slaqr0</code> DOUBLE PRECISION for <code>dlaqr0</code> COMPLEX for <code>claqr0</code> COMPLEX*16 for <code>zlaqr0</code>. Workspace array with dimension <i>lwork</i>.</p>
<i>lwork</i>	<p>INTEGER. The dimension of the array <i>work</i>. $lwork \geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6*n$. It is recommended to use the workspace query to determine the optimal workspace size. If <i>lwork</i>=-1, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters n, <i>ilo</i>, and <i>ihl</i>. The estimate is returned in <i>work</i>(1). No error messages related to the <i>lwork</i> is issued by <code>xerbla</code>. Neither H nor z are accessed.</p>

Output Parameters

<i>h</i>	<p>If <i>info</i>=0, and <i>wantt</i> is <code>.TRUE.</code>, then h contains the upper quasi-triangular/triangular matrix T from the Schur decomposition (the Schur form). If <i>info</i>=0, and <i>wantt</i> is <code>.FALSE.</code>, then the contents of h are unspecified on exit.</p>
----------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	(The output values of h when $info > 0$ are given under the description of the $info$ parameter below.) The routine may explicitly set $h(i, j)$ for $i > j$ and $j = 1, 2, \dots, ilo-1$ or $j = ihi+1, ihi+2, \dots, n$.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
w	COMPLEX for $claqr0$ COMPLEX*16 for $zlaqr0$. Arrays, DIMENSION(n). The computed eigenvalues of $h(ilo:ihi, ilo:ihi)$ are stored in $w(ilo:ihi)$. If $wantt$ is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $w(i) = h(i, i)$.
wr, wi	REAL for $slaqr0$ DOUBLE PRECISION for $dlaqr0$ Arrays, DIMENSION(ihi) each. The real and imaginary parts, respectively, of the computed eigenvalues of $h(ilo:ihi, ilo:ihi)$ are stored in the $wr(ilo:ihi)$ and $wi(ilo:ihi)$. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi , say the i -th and $(i+1)$ -th, with $wi(i) > 0$ and $wi(i+1) < 0$. If $wantt$ is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $wr(i) = h(i, i)$, and if $h(i:i+1, i:i+1)$ is a 2-by-2 diagonal block, then $wi(i) = \sqrt{-h(i+1, i) * h(i, i+1)}$.
z	If $wantz$ is .TRUE., then $z(ilo:ihi, iloz:ihiz)$ is replaced by $z(ilo:ihi, iloz:ihiz) * U$, where U is the orthogonal/unitary Schur factor of $h(ilo:ihi, ilo:ihi)$. If $wantz$ is .FALSE., z is not referenced. (The output values of z when $info > 0$ are given under the description of the $info$ parameter below.)
$info$	INTEGER. = 0: the execution is successful.

> 0: if *info* = *i*, then the routine failed to compute all the eigenvalues. Elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

> 0: if *wantt* is *.FALSE.*, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final output value of *h*.

> 0: if *wantt* is *.TRUE.*, then (initial value of *h*) * *U* = *U* * (final value of *h*, where *U* is an orthogonal/unitary matrix. The final value of *h* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info*+1 through *ihi*.

> 0: if *wantz* is *.TRUE.*, then (final value of *z*(*ilo:ihi*, *iloz:ihiz*)) = (initial value of *z*(*ilo:ihi*, *iloz:ihiz*) * *U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz* is *.FALSE.*, then *z* is not accessed.

?laqr1

*Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix *H* and specified shifts.*

Syntax

```
call slaqr1( n, h, ldh, sr1, sil, sr2, si2, v )
call dlaqr1( n, h, ldh, sr1, sil, sr2, si2, v )
call claqr1( n, h, ldh, s1, s2, v )
call zlaqr1( n, h, ldh, s1, s2, v )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

Given a 2-by-2 or 3-by-3 matrix *H*, this routine sets *v* to a scalar multiple of the first column of the product

$K = (H - s1*I)*(H - s2*I)$, or $K = (H - (sr1 + i*si1)*I)*(H - (sr2 + i*si2)*I)$

scaling to avoid overflows and most underflows.

It is assumed that either 1) $sr1 = sr2$ and $si1 = -si2$, or 2) $si1 = si2 = 0$.

This is useful for starting double implicit shift bulges in the QR algorithm.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>H</i> . <i>n</i> must be equal to 2 or 3.
<i>sr1, si2, sr2, si2</i>	REAL for slaqr1 DOUBLE PRECISION for dlaqr1 Shift values that define <i>K</i> in the formula above.
<i>s1, s2</i>	COMPLEX for claqr1 COMPLEX*16 for zlaqr1. Shift values that define <i>K</i> in the formula above.
<i>h</i>	REAL for slaqr1 DOUBLE PRECISION for dlaqr1 COMPLEX for claqr1 COMPLEX*16 for zlaqr1. Array, DIMENSION (<i>ldh, n</i>), contains 2-by-2 or 3-by-3 matrix <i>H</i> in the formula above.
<i>ldh</i>	INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling routine. $ldh \geq n$.

Output Parameters

<i>v</i>	REAL for slaqr1 DOUBLE PRECISION for dlaqr1 COMPLEX for claqr1 COMPLEX*16 for zlaqr1. Array with dimension (<i>n</i>). A scalar multiple of the first column of the matrix <i>K</i> in the formula above.
----------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

?laqr2

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call slaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call dlaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call claqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call zlaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine accepts as input an upper Hessenberg matrix H and performs an orthogonal/unitary similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H has been overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal/unitary similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

This subroutine is identical to ?laqr3 except that it avoids recursion by calling ?lahqr instead of ?laqr4.

Input Parameters

<code>wantt</code>	LOGICAL. If <code>wantt = .TRUE.</code> , then the Hessenberg matrix H is fully updated so that the quasi-triangular/triangular Schur factor may be computed (in cooperation with the calling subroutine).
--------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	<p>If <i>wantt</i> = <code>.FALSE.</code>, then only enough of <i>H</i> is updated to preserve the eigenvalues.</p>
<i>wantz</i>	<p>LOGICAL.</p> <p>If <i>wantz</i> = <code>.TRUE.</code>, then the orthogonal/unitary matrix <i>Z</i> is updated so that the orthogonal/unitary Schur factor may be computed (in cooperation with the calling subroutine). If <i>wantz</i> = <code>.FALSE.</code>, then <i>Z</i> is not referenced.</p>
<i>n</i>	<p>INTEGER. The order of the Hessenberg matrix <i>H</i> and (if <i>wantz</i> = <code>.TRUE.</code>) the order of the orthogonal/unitary matrix <i>Z</i>.</p>
<i>ktop</i>	<p>INTEGER.</p> <p>It is assumed that either <i>ktop</i>=1 or <i>h</i>(<i>ktop</i>,<i>ktop</i>-1)=0. <i>ktop</i> and <i>kbot</i> together determine an isolated block along the diagonal of the Hessenberg matrix.</p>
<i>kbot</i>	<p>INTEGER.</p> <p>It is assumed without a check that either <i>kbot</i>=<i>n</i> or <i>h</i>(<i>kbot</i>+1,<i>kbot</i>)=0. <i>ktop</i> and <i>kbot</i> together determine an isolated block along the diagonal of the Hessenberg matrix.</p>
<i>nw</i>	<p>INTEGER.</p> <p>Size of the deflation window. $1 \leq nw \leq (kbot-ktop+1)$.</p>
<i>h</i>	<p>REAL for slaqr2 DOUBLE PRECISION for dlaqr2 COMPLEX for claqr2 COMPLEX*16 for zlaqr2.</p> <p>Array, DIMENSION (<i>ldh</i>, <i>n</i>), on input the initial <i>n</i>-by-<i>n</i> section of <i>h</i> stores the Hessenberg matrix <i>H</i> undergoing aggressive early deflation.</p>
<i>ldh</i>	<p>INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling subroutine. <i>ldh</i>≥<i>n</i>.</p>
<i>iloz</i> , <i>ihiz</i>	<p>INTEGER. Specify the rows of <i>Z</i> to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code>. $1 \leq iloz \leq ihiz \leq n$.</p>
<i>z</i>	<p>REAL for slaqr2 DOUBLE PRECISION for dlaqr2 COMPLEX for claqr2</p>

COMPLEX*16 for zlaqr2.
Array, DIMENSION (*ldz*, *ihi*), contains the matrix *z* if *wantz* is .TRUE.. If *wantz* is .FALSE., then *z* is not referenced.

ldz INTEGER. The leading dimension of the array *z* just as declared in the calling subroutine. $ldz \geq 1$.

v REAL for slaqr2
DOUBLE PRECISION for dlaqr2
COMPLEX for claqr2
COMPLEX*16 for zlaqr2.
Workspace array with dimension (*ldv*, *nw*). An *nw*-by-*nw* work array.

ldv INTEGER. The leading dimension of the array *v* just as declared in the calling subroutine. $ldv \geq nw$.

nh INTEGER. The number of column of *t*. $nh \geq nw$.

t REAL for slaqr2
DOUBLE PRECISION for dlaqr2
COMPLEX for claqr2
COMPLEX*16 for zlaqr2.
Workspace array with dimension (*ldt*, *nw*).

ldt INTEGER. The leading dimension of the array *t* just as declared in the calling subroutine. $ldt \geq nw$.

nv INTEGER. The number of rows of work array *wv* available for workspace. $nv \geq nw$.

wv REAL for slaqr2
DOUBLE PRECISION for dlaqr2
COMPLEX for claqr2
COMPLEX*16 for zlaqr2.
Workspace array with dimension (*ldwv*, *nw*).

ldwv INTEGER. The leading dimension of the array *wv* just as declared in the calling subroutine. $ldwv \geq nw$.

work REAL for slaqr2
DOUBLE PRECISION for dlaqr2
COMPLEX for claqr2

lwork COMPLEX*16 for *zlaqr2*.
Workspace array with dimension *lwork*.
INTEGER. The dimension of the array *work*.
*lwork=2*nw*) is sufficient, but for the optimal performance
a greater workspace may be required.
If *lwork=-1*, then the routine performs a workspace query:
it estimates the optimal workspace size for the given values
of the input parameters *n*, *nw*, *ktop*, and *kbot*. The estimate
is returned in *work(1)*. No error messages related to the
lwork is issued by *xerbla*. Neither *H* nor *Z* are accessed.

Output Parameters

h On output *h* has been transformed by an orthogonal/unitary
similarity transformation, perturbed, and the returned to
Hessenberg form that (it is to be hoped) has some zero
subdiagonal entries.

work(1) On exit *work(1)* is set to an estimate of the optimal value
of *lwork* for the given values of the input parameters *n*,
nw, *ktop*, and *kbot*.

z If *wantz* is *.TRUE.*, then the orthogonal/unitary similarity
transformation is accumulated into *z(ilo:ihiz, ilo:ihi)*
from the right.
If *wantz* is *.FALSE.*, then *z* is unreferenced.

nd INTEGER. The number of converged eigenvalues uncovered
by the routine.

ns INTEGER. The number of unconverged, that is approximate
eigenvalues returned in *sr*, *si* or in *sh* that may be used
as shifts by the calling subroutine.

sh COMPLEX for *claqr2*
COMPLEX*16 for *zlaqr2*.
Arrays, DIMENSION (*kbot*).
The approximate eigenvalues that may be used for shifts
are stored in the *sh(kbot-nd-ns+1)* through the
sh(kbot-nd).
The converged eigenvalues are stored in the
sh(kbot-nd+1) through the *sh(kbot)*.

sr, si REAL for slaqr2
 DOUBLE PRECISION for dlaqr2
 Arrays, DIMENSION (*kbot*) each.
 The real and imaginary parts of the approximate eigenvalues that may be used for shifts are stored in the *sr(kbot-nd-ns+1)* through the *sr(kbot-nd)*, and *si(kbot-nd-ns+1)* through the *si(kbot-nd)*, respectively. The real and imaginary parts of converged eigenvalues are stored in the *sr(kbot-nd+1)* through the *sr(kbot)*, and *si(kbot-nd+1)* through the *si(kbot)*, respectively.

!laqr3

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call slaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call dlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call claqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call zlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine accepts as input an upper Hessenberg matrix *H* and performs an orthogonal/unitary similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output *H* has been overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal/unitary similarity transformation of *H*. It is to be hoped that the final version of *H* has many zero subdiagonal entries.

Input Parameters

<i>wantt</i>	<p>LOGICAL.</p> <p>If <i>wantt</i> = .TRUE., then the Hessenberg matrix <i>H</i> is fully updated so that the quasi-triangular/triangular Schur factor may be computed (in cooperation with the calling subroutine).</p> <p>If <i>wantt</i> = .FALSE., then only enough of <i>H</i> is updated to preserve the eigenvalues.</p>
<i>wantz</i>	<p>LOGICAL.</p> <p>If <i>wantz</i> = .TRUE., then the orthogonal/unitary matrix <i>Z</i> is updated so that the orthogonal/unitary Schur factor may be computed (in cooperation with the calling subroutine).</p> <p>If <i>wantz</i> = .FALSE., then <i>Z</i> is not referenced.</p>
<i>n</i>	<p>INTEGER. The order of the Hessenberg matrix <i>H</i> and (if <i>wantz</i> = .TRUE.) the order of the orthogonal/unitary matrix <i>Z</i>.</p>
<i>ktop</i>	<p>INTEGER.</p> <p>It is assumed that either <i>ktop</i>=1 or <i>h</i>(<i>ktop</i>,<i>ktop</i>-1)=0. <i>ktop</i> and <i>kbot</i> together determine an isolated block along the diagonal of the Hessenberg matrix.</p>
<i>kbot</i>	<p>INTEGER.</p> <p>It is assumed without a check that either <i>kbot</i>=<i>n</i> or <i>h</i>(<i>kbot</i>+1,<i>kbot</i>)=0. <i>ktop</i> and <i>kbot</i> together determine an isolated block along the diagonal of the Hessenberg matrix.</p>
<i>nw</i>	<p>INTEGER.</p> <p>Size of the deflation window. $1 \leq nw \leq (kbot - ktop + 1)$.</p>
<i>h</i>	<p>REAL for slaqr3 DOUBLE PRECISION for dlaqr3 COMPLEX for claqr3 COMPLEX*16 for zlaqr3.</p> <p>Array, DIMENSION (<i>ldh</i>, <i>n</i>), on input the initial <i>n</i>-by-<i>n</i> section of <i>h</i> stores the Hessenberg matrix <i>H</i> undergoing aggressive early deflation.</p>
<i>ldh</i>	<p>INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling subroutine. $ldh \geq n$.</p>

<i>iloz, ihiz</i>	INTEGER. Specify the rows of <i>z</i> to which transformations must be applied if <i>wantz</i> is <i>.TRUE.</i> . $1 \leq iloz \leq ihiz \leq n$.
<i>z</i>	REAL for <i>slaqr3</i> DOUBLE PRECISION for <i>dlaqr3</i> COMPLEX for <i>claqr3</i> COMPLEX*16 for <i>zlaqr3</i> . Array, DIMENSION (<i>ldz</i> , <i>ihi</i>), contains the matrix <i>z</i> if <i>wantz</i> is <i>.TRUE.</i> . If <i>wantz</i> is <i>.FALSE.</i> , then <i>z</i> is not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> just as declared in the calling subroutine. $ldz \geq 1$.
<i>v</i>	REAL for <i>slaqr3</i> DOUBLE PRECISION for <i>dlaqr3</i> COMPLEX for <i>claqr3</i> COMPLEX*16 for <i>zlaqr3</i> . Workspace array with dimension (<i>ldv</i> , <i>nw</i>). An <i>nw</i> -by- <i>nw</i> work array.
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling subroutine. $ldv \geq nw$.
<i>nh</i>	INTEGER. The number of column of <i>t</i> . $nh \geq nw$.
<i>t</i>	REAL for <i>slaqr3</i> DOUBLE PRECISION for <i>dlaqr3</i> COMPLEX for <i>claqr3</i> COMPLEX*16 for <i>zlaqr3</i> . Workspace array with dimension (<i>ldt</i> , <i>nw</i>).
<i>ldt</i>	INTEGER. The leading dimension of the array <i>t</i> just as declared in the calling subroutine. $ldt \geq nw$.
<i>nv</i>	INTEGER. The number of rows of work array <i>wv</i> available for workspace. $nv \geq nw$.
<i>wv</i>	REAL for <i>slaqr3</i> DOUBLE PRECISION for <i>dlaqr3</i> COMPLEX for <i>claqr3</i> COMPLEX*16 for <i>zlaqr3</i> . Workspace array with dimension (<i>ldwv</i> , <i>nw</i>).

<i>ldwv</i>	INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling subroutine. $ldwv \geq nw$.
<i>work</i>	REAL for slaqr3 DOUBLE PRECISION for dlaqr3 COMPLEX for claqr3 COMPLEX*16 for zlaqr3. Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork=2*nw$) is sufficient, but for the optimal performance a greater workspace may be required. If $lwork=-1$, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters <i>n</i> , <i>nw</i> , <i>ktop</i> , and <i>kbot</i> . The estimate is returned in <i>work(1)</i> . No error messages related to the <i>lwork</i> is issued by xerbla. Neither <i>H</i> nor <i>Z</i> are accessed.

Output Parameters

<i>h</i>	On output <i>h</i> has been transformed by an orthogonal/unitary similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
<i>work(1)</i>	On exit <i>work(1)</i> is set to an estimate of the optimal value of <i>lwork</i> for the given values of the input parameters <i>n</i> , <i>nw</i> , <i>ktop</i> , and <i>kbot</i> .
<i>z</i>	If <i>wantz</i> is .TRUE., then the orthogonal/unitary similarity transformation is accumulated into <i>z(ilo:ihiz, ilo:ihi)</i> from the right. If <i>wantz</i> is .FALSE., then <i>z</i> is unreferenced.
<i>nd</i>	INTEGER. The number of converged eigenvalues uncovered by the routine.
<i>ns</i>	INTEGER. The number of unconverged, that is approximate eigenvalues returned in <i>sr</i> , <i>si</i> or in <i>sh</i> that may be used as shifts by the calling subroutine.
<i>sh</i>	COMPLEX for claqr3 COMPLEX*16 for zlaqr3. Arrays, DIMENSION (<i>kbot</i>).

The approximate eigenvalues that may be used for shifts are stored in the $sh(kbot-nd-ns+1)$ through the $sh(kbot-nd)$.

The converged eigenvalues are stored in the $sh(kbot-nd+1)$ through the $sh(kbot)$.

sr, si

REAL for slaqr3

DOUBLE PRECISION for dlaqr3

Arrays, DIMENSION ($kbot$) each.

The real and imaginary parts of the approximate eigenvalues that may be used for shifts are stored in the

$sr(kbot-nd-ns+1)$ through the $sr(kbot-nd)$, and

$si(kbot-nd-ns+1)$ through the $si(kbot-nd)$, respectively.

The real and imaginary parts of converged eigenvalues are stored in the $sr(kbot-nd+1)$ through the $sr(kbot)$, and $si(kbot-nd+1)$ through the $si(kbot)$, respectively.

?laqr4

Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.

Syntax

```
call slaqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )
```

```
call dlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )
```

```
call claqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )
```

```
call zlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H=Z^*T^*Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q^*H^*Q^H = (QZ)^*H^*(QZ)^H$.

This routine implements one level of recursion for `?laqr0`. It is a complete implementation of the small bulge multi-shift QR algorithm. It may be called by `?laqr0` and, for large enough deflation window size, it may be called by `?laqr3`. This routine is identical to `?laqr0` except that it calls `?laqr2` instead of `?laqr3`.

Input Parameters

<code>wantt</code>	LOGICAL. If <code>wantt = .TRUE.</code> , the full Schur form T is required; If <code>wantt = .FALSE.</code> , only eigenvalues are required.
<code>wantz</code>	LOGICAL. If <code>wantz = .TRUE.</code> , the matrix of Schur vectors Z is required; If <code>wantz = .FALSE.</code> , Schur vectors are not required.
<code>n</code>	INTEGER. The order of the Hessenberg matrix H . ($n \geq 0$).
<code>ilo, ihi</code>	INTEGER. It is assumed that H is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$, and if $ilo > 1$ then $h(ilo, ilo-1) = 0$. ilo and ihi are normally set by a previous call to <code>cgebal</code> , and then passed to <code>cgehrd</code> when the matrix output by <code>cgebal</code> is reduced to Hessenberg form. Otherwise, ilo and ihi should be set to 1 and n , respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n=0$, then $ilo=1$ and $ihi=0$
<code>h</code>	REAL for <code>slaqr4</code> DOUBLE PRECISION for <code>dlaqr4</code> COMPLEX for <code>claqr4</code> COMPLEX*16 for <code>zlaqr4</code> .

Array, DIMENSION (ldh, n), contains the upper Hessenberg matrix H .

ldh INTEGER. The leading dimension of the array h . $ldh \geq \max(1, n)$.

iloz, ihiz INTEGER. Specify the rows of z to which transformations must be applied if *wantz* is `.TRUE.`, $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$.

z REAL for slaqr4
DOUBLE PRECISION for dlaqr4
COMPLEX for claqr4
COMPLEX*16 for zlaqr4.
Array, DIMENSION (ldz, ihi), contains the matrix z if *wantz* is `.TRUE.`. If *wantz* is `.FALSE.`, z is not referenced.

ldz INTEGER. The leading dimension of the array z .
If *wantz* is `.TRUE.`, then $ldz \geq \max(1, ihiz)$. Otherwise, $ldz \geq 1$.

work REAL for slaqr4
DOUBLE PRECISION for dlaqr4
COMPLEX for claqr4
COMPLEX*16 for zlaqr4.
Workspace array with dimension *lwork*.

lwork INTEGER. The dimension of the array *work*.
 $lwork \geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6*n$.
It is recommended to use the workspace query to determine the optimal workspace size. If *lwork*=-1, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters n , *ilo*, and *ihi*. The estimate is returned in *work*(1). No error messages related to the *lwork* is issued by xerbla. Neither H nor z are accessed.

Output Parameters

<i>h</i>	<p>If <i>info</i>=0 , and <i>wantt</i> is <i>.TRUE.</i> , then <i>h</i> contains the upper quasi-triangular/triangular matrix <i>T</i> from the Schur decomposition (the Schur form).</p> <p>If <i>info</i>=0 , and <i>wantt</i> is <i>.FALSE.</i> , then the contents of <i>h</i> are unspecified on exit.</p> <p>(The output values of <i>h</i> when <i>info</i> > 0 are given under the description of the <i>info</i> parameter below.)</p> <p>The routines may explicitly set <i>h</i>(<i>i</i>,<i>j</i>) for <i>i</i>><i>j</i> and <i>j</i>=1,2,...<i>ilo</i>-1 or <i>j</i>=<i>ihi</i>+1, <i>ihi</i>+2,...<i>n</i>.</p>
<i>work</i> (1)	<p>On exit <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance.</p>
<i>w</i>	<p>COMPLEX for <i>claqr4</i> COMPLEX*16 for <i>zlaqr4</i>.</p> <p>Arrays, DIMENSION(<i>n</i>). The computed eigenvalues of <i>h</i>(<i>ilo</i>:<i>ihi</i>, <i>ilo</i>:<i>ihi</i>) are stored in <i>w</i>(<i>ilo</i>:<i>ihi</i>). If <i>wantt</i> is <i>.TRUE.</i> , then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i>, with <i>w</i>(<i>i</i>) = <i>h</i>(<i>i</i>,<i>i</i>).</p>
<i>wr</i> , <i>wi</i>	<p>REAL for <i>slaqr4</i> DOUBLE PRECISION for <i>dlaqr4</i></p> <p>Arrays, DIMENSION(<i>ihi</i>) each. The real and imaginary parts, respectively, of the computed eigenvalues of <i>h</i>(<i>ilo</i>:<i>ihi</i>, <i>ilo</i>:<i>ihi</i>) are stored in the <i>wr</i>(<i>ilo</i>:<i>ihi</i>) and <i>wi</i>(<i>ilo</i>:<i>ihi</i>). If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i>, say the <i>i</i>-th and (<i>i</i>+1)-th, with <i>wi</i>(<i>i</i>)> 0 and <i>wi</i>(<i>i</i>+1) < 0. If <i>wantt</i> is <i>.TRUE.</i> , then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i>, with <i>wr</i>(<i>i</i>) = <i>h</i>(<i>i</i>,<i>i</i>), and if <i>h</i>(<i>i</i>:<i>i</i>+1,<i>i</i>:<i>i</i>+1) is a 2-by-2 diagonal block, then <i>wi</i>(<i>i</i>)=sqrt(-<i>h</i>(<i>i</i>+1,<i>i</i>)*<i>h</i>(<i>i</i>,<i>i</i>+1)).</p>
<i>z</i>	<p>If <i>wantz</i> is <i>.TRUE.</i> , then <i>z</i>(<i>ilo</i>:<i>ihi</i>, <i>iloz</i>:<i>ihiz</i>) is replaced by <i>z</i>(<i>ilo</i>:<i>ihi</i>, <i>iloz</i>:<i>ihiz</i>)*<i>U</i>, where <i>U</i> is the orthogonal/unitary Schur factor of <i>h</i>(<i>ilo</i>:<i>ihi</i>, <i>ilo</i>:<i>ihi</i>). If <i>wantz</i> is <i>.FALSE.</i> , <i>z</i> is not referenced.</p>

(The output values of z when $info > 0$ are given under the description of the *info* parameter below.)

info

INTEGER.

= 0: the execution is successful.

> 0: if $info = i$, then the routine failed to compute all the eigenvalues. Elements $1:ilo-1$ and $i+1:n$ of wr and wi contain those eigenvalues which have been successfully computed.

> 0: if *wantt* is .FALSE., then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final output value of *h*.

> 0: if *wantt* is .TRUE., then (initial value of *h*) * *U* = *U* * (final value of *h*, where *U* is an orthogonal/unitary matrix. The final value of *h* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info*+1 through *ihi*.

> 0: if *wantz* is .TRUE., then (final value of $z(ilo:ihi, iloz:ihiz)$) = (initial value of $z(ilo:ihi, iloz:ihiz)$) * *U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz* is .FALSE., then *z* is not accessed.

?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

```
call slaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh,
            iloz, ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

```
call dlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh,
            iloz, ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

```
call claqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, s, h, ldh, iloz,
            ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

```
call zlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, s, h, ldh, iloz,
            ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

This auxiliary routine called by `?laqr0` performs a single small-bulge multi-shift QR sweep.

Input Parameters

<i>wantt</i>	LOGICAL. <i>wantt</i> = .TRUE. if the quasi-triangular/triangular Schur factor is computed. <i>wantt</i> is set to .FALSE. otherwise.
<i>wantz</i>	LOGICAL. <i>wantz</i> = .TRUE. if the orthogonal/unitary Schur factor is computed. <i>wantz</i> is set to .FALSE. otherwise.
<i>kacc22</i>	INTEGER. Possible values are 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: the routine does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: the routine accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: the routine accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<i>n</i>	INTEGER. The order of the Hessenberg matrix <i>H</i> upon which the routine operates.
<i>ktop, kbot</i>	INTEGER. It is assumed without a check that either <i>ktop</i> =1 or <i>h(ktop,ktop-1)</i> =0, and either <i>kbot</i> = <i>n</i> or <i>h(kbot+1,kbot)</i> =0.
<i>nshfts</i>	INTEGER. Number of simultaneous shifts, must be positive and even.
<i>sr, si</i>	REAL for <code>slaqr5</code>

DOUBLE PRECISION for `dlaqr5`
 Arrays, DIMENSION (*nshfts*) each.
sr contains the real parts and *si* contains the
 imaginary parts of the *nshfts* shifts of origin that
 define the multi-shift QR sweep.

s COMPLEX for `claqr5`
 COMPLEX*16 for `zlaqr5`.
 Arrays, DIMENSION (*nshfts*).
s contains the shifts of origin that define the multi-shift
 QR sweep.

h REAL for `slaqr5`
 DOUBLE PRECISION for `dlaqr5`
 COMPLEX for `claqr5`
 COMPLEX*16 for `zlaqr5`.
 Array, DIMENSION (*ldh*, *n*), on input contains the
 Hessenberg matrix.

ldh INTEGER. The leading dimension of the array *h* just as
 declared in the calling routine. $ldh \geq \max(1, n)$.

iloz, *ihiz* INTEGER. Specify the rows of *z* to which transformations
 must be applied if *wantz* is .TRUE.. $1 \leq iloz \leq ihiz \leq$
n.

z REAL for `slaqr5`
 DOUBLE PRECISION for `dlaqr5`
 COMPLEX for `claqr5`
 COMPLEX*16 for `zlaqr5`.
 Array, DIMENSION (*ldz*, *ihi*), contains the matrix *z* if
wantz is .TRUE.. If *wantz* is .FALSE., then *z* is not
 referenced.

ldz INTEGER. The leading dimension of the array *z* just as
 declared in the calling routine. $ldz \geq n$.

v REAL for `slaqr5`
 DOUBLE PRECISION for `dlaqr5`
 COMPLEX for `claqr5`
 COMPLEX*16 for `zlaqr5`.
 Workspace array with dimension (*ldv*, *nshfts*/2).

<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling routine. $ldv \geq 3$.
<i>u</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 COMPLEX for claqr5 COMPLEX*16 for zlaqr5. Workspace array with dimension $(ldu, 3*nshfts-3)$.
<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i> just as declared in the calling routine. $ldu \geq 3*nshfts-3$.
<i>nh</i>	INTEGER. The number of column in the array <i>wh</i> available for workspace. $nh \geq 1$.
<i>wh</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 COMPLEX for claqr5 COMPLEX*16 for zlaqr5. Workspace array with dimension $(ldwh, nh)$
<i>ldwh</i>	INTEGER. The leading dimension of the array <i>wh</i> just as declared in the calling routine. $ldwh \geq 3*nshfts-3$
<i>nv</i>	INTEGER. The number of rows of the array <i>wv</i> available for workspace. $nv \geq 1$.
<i>wv</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 COMPLEX for claqr5 COMPLEX*16 for zlaqr5. Workspace array with dimension $(ldwv, 3*nshfts-3)$.
<i>ldwv</i>	INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling routine. $ldwv \geq nv$.

Output Parameters

<i>h</i>	On output a multi-shift QR Sweep with shifts $sr(j)+i*si(j)$ or $s(j)$ is applied to the isolated diagonal block in rows and columns <i>ktop</i> through <i>kbot</i> .
----------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------

z If *wantz* is `.TRUE.`, then the QR Sweep orthogonal/unitary similarity transformation is accumulated into *z*(*iloz:ihiz*, *ilo:ihi*) from the right.
 If *wantz* is `.FALSE.`, then *z* is unreferenced.

?laqsb

Scales a symmetric band matrix, using scaling factors computed by ?pbequ.

Syntax

```
call slaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call dlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call claqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call zlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine equilibrates a symmetric band matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix <i>A</i> if <i>uplo</i> = 'U', or the number of sub-diagonals if <i>uplo</i> = 'L'. $kd \geq 0$.
<i>ab</i>	REAL for slaqsb

DOUBLE PRECISION for dlaqsb
 COMPLEX for claqsb
 COMPLEX*16 for zlaqsb
Array, DIMENSION ($ldab, n$). On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array ab as follows:
 if $uplo = 'U'$, $ab(kd+1+i-j, j) = A(i, j)$ for
 $\max(1, j-kd) \leq i \leq j$;
 if $uplo = 'L'$, $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.
ldab INTEGER. The leading dimension of the array ab .
 $ldab \geq kd+1$.
s REAL for slaqsb/claqsb
 DOUBLE PRECISION for dlaqsb/zlaqsb
Array, DIMENSION (n). The scale factors for A .
scond REAL for slaqsb/claqsb
 DOUBLE PRECISION for dlaqsb/zlaqsb
 Ratio of the smallest $s(i)$ to the largest $s(i)$.
amax REAL for slaqsb/claqsb
 DOUBLE PRECISION for dlaqsb/zlaqsb
 Absolute value of largest matrix entry.

Output Parameters

ab On exit, if $info = 0$, the triangular factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$ of the band matrix A , in the same storage format as A .
equed CHARACTER*1.
 Specifies whether or not equilibration was done.
 If $equed = 'N'$: No equilibration.
 If $equed = 'Y'$: Equilibration was done, that is, A has been replaced by $diag(s) * A * diag(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqsp

Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ.

Syntax

```
call slaqsp( uplo, n, ap, s, acond, amax, equed )
call dlaqsp( uplo, n, ap, s, acond, amax, equed )
call claqsp( uplo, n, ap, s, acond, amax, equed )
call zlaqsp( uplo, n, ap, s, acond, amax, equed )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?laqsp equilibrates a symmetric matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>ap</i>	REAL for slaqsp DOUBLE PRECISION for dlaqsp COMPLEX for claqsp

COMPLEX*16 for zlaqsp
 Array, DIMENSION $(n(n+1)/2)$.
 On entry, the upper or lower triangle of the symmetric matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array ap as follows:
 if $uplo = 'U'$, $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;
 if $uplo = 'L'$, $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

s REAL for slaqsp/claqsp
 DOUBLE PRECISION for dlaqsp/zlaqsp
 Array, DIMENSION (n) . The scale factors for A .

$scond$ REAL for slaqsp/claqsp
 DOUBLE PRECISION for dlaqsp/zlaqsp
 Ratio of the smallest $s(i)$ to the largest $s(i)$.

$amax$ REAL for slaqsp/claqsp
 DOUBLE PRECISION for dlaqsp/zlaqsp
 Absolute value of largest matrix entry.

Output Parameters

ap On exit, the equilibrated matrix: $diag(s) * A * diag(s)$, in the same storage format as A .

$equed$ CHARACTER*1.
 Specifies whether or not equilibration was done.
 If $equed = 'N'$: No equilibration.
 If $equed = 'Y'$: Equilibration was done, that is, A has been replaced by $diag(s) * A * diag(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < thresh$, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > large$ or $amax < small$, scaling is done.

?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ.

Syntax

```
call slaqsy( uplo, n, a, lda, s, scond, amax, equed )
call dlaqsy( uplo, n, a, lda, s, scond, amax, equed )
call claqsy( uplo, n, a, lda, s, scond, amax, equed )
call zlaqsy( uplo, n, a, lda, s, scond, amax, equed )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine equilibrates a symmetric matrix A using the scaling factors in the vector s .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>a</i>	REAL for slaqsy DOUBLE PRECISION for dlaqsy COMPLEX for claqsy COMPLEX*16 for zlaqsy Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the symmetric matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

	If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(n, 1)$.
<i>s</i>	REAL for slaqsy/claqsy DOUBLE PRECISION for dlaqsy/zlaqsy Array, DIMENSION (<i>n</i>). The scale factors for <i>A</i> .
<i>scond</i>	REAL for slaqsy/claqsy DOUBLE PRECISION for dlaqsy/zlaqsy Ratio of the smallest <i>s</i> (<i>i</i>) to the largest <i>s</i> (<i>i</i>).
<i>amax</i>	REAL for slaqsy/claqsy DOUBLE PRECISION for dlaqsy/zlaqsy Absolute value of largest matrix entry.

Output Parameters

<i>a</i>	On exit, if <i>equed</i> = 'Y', the equilibrated matrix: $\text{diag}(s) * A * \text{diag}(s)$.
<i>equed</i>	CHARACTER*1. Specifies whether or not equilibration was done. If <i>equed</i> = 'N': No equilibration. If <i>equed</i> = 'Y': Equilibration was done, i.e., <i>A</i> has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqtr

Solves a real quasi-triangular system of equations, or a complex quasi-triangular system of special form, in real arithmetic.

Syntax

```
call slaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
call dlaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?laqtr solves the real quasi-triangular system

$\text{op}(T) * p = \text{scale} * c$, if `lreal = .TRUE.`

or the complex quasi-triangular systems

$\text{op}(T + iB) * (p + iq) = \text{scale} * (c + id)$, if `lreal = .FALSE.`

in real arithmetic, where T is upper quasi-triangular.

If `lreal = .FALSE.`, then the first diagonal block of T must be 1-by-1, B is the specially structured matrix

$$B = \begin{bmatrix} b_1 & b_2 & \dots & \dots & b_n \\ & W & & & \\ & & W & & \\ & & & \dots & \\ & & & & W \end{bmatrix}$$

$\text{op}(A) = A$ or A' , A' denotes the conjugate transpose of matrix A .

On input,

$$x = \begin{bmatrix} c \\ d \end{bmatrix}, \text{ on output } x = \begin{bmatrix} p \\ q \end{bmatrix}$$

This routine is designed for the condition number estimation in routine `?trsna`.

Input Parameters

<i>ltran</i>	LOGICAL. On entry, <i>ltran</i> specifies the option of conjugate transpose: = <code>.FALSE.</code> , $\text{op}(T + iB) = T + iB$, = <code>.TRUE.</code> , $\text{op}(T + iB) = (T + iB)'$.
<i>lreal</i>	LOGICAL. On entry, <i>lreal</i> specifies the input matrix structure: = <code>.FALSE.</code> , the input is complex = <code>.TRUE.</code> , the input is real.
<i>n</i>	INTEGER. On entry, <i>n</i> specifies the order of $T + iB$. $n \geq 0$.
<i>t</i>	REAL for <code>slaqtr</code> DOUBLE PRECISION for <code>dlaqtr</code> Array, dimension (ldt, n) . On entry, <i>t</i> contains a matrix in Schur canonical form. If <i>lreal</i> = <code>.FALSE.</code> , then the first diagonal block of <i>t</i> must be 1-by-1.
<i>ldt</i>	INTEGER. The leading dimension of the matrix <i>T</i> . $ldt \geq \max(1, n)$.
<i>b</i>	REAL for <code>slaqtr</code> DOUBLE PRECISION for <code>dlaqtr</code> Array, dimension (n) . On entry, <i>b</i> contains the elements to form the matrix <i>B</i> as described above. If <i>lreal</i> = <code>.TRUE.</code> , <i>b</i> is not referenced.
<i>w</i>	REAL for <code>slaqtr</code> DOUBLE PRECISION for <code>dlaqtr</code> On entry, <i>w</i> is the diagonal element of the matrix <i>B</i> . If <i>lreal</i> = <code>.TRUE.</code> , <i>w</i> is not referenced.

x REAL for `slaqtr`
 DOUBLE PRECISION for `dlaqtr`
 Array, dimension $(2n)$. On entry, *x* contains the right hand side of the system.

work REAL for `slaqtr`
 DOUBLE PRECISION for `dlaqtr`
 Workspace array, dimension (n) .

Output Parameters

scale REAL for `slaqtr`
 DOUBLE PRECISION for `dlaqtr`
 On exit, *scale* is the scale factor.

x On exit, *x* is overwritten by the solution.

info INTEGER.
 If *info* = 0: successful exit.
 If *info* = 1: the some diagonal 1-by-1 block has been perturbed by a small number `smin` to keep nonsingularity.
 If *info* = 2: the some diagonal 2-by-2 block has been perturbed by a small number in `?1aln2` to keep nonsingularity.

NOTE. For higher speed, this routine does not check the inputs for errors.

?lar1v

Computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of tridiagonal matrix.

Syntax

```
call slar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )

call dlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )

call clar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )

call zlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lar1v` computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of the tridiagonal matrix $L^*D^*L^T - \lambda^*I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude.

The following steps accomplish this computation :

- Stationary qd transform, $L^*D^*L^T - \lambda^*I = L(+)*D(+)*L(+)^T$
- Progressive qd transform, $L^*D^*L^T - \lambda^*I = U(-)*D(-)*U(-)^T$,
- Computation of the diagonal elements of the inverse of $L^*D^*L^T - \lambda^*I$ by combining the above transforms, and choosing r as the index where the diagonal of the inverse is (one of the) largest in magnitude.
- Computation of the (scaled) r -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix $L*D*L^T$.
<i>b1</i>	INTEGER. First index of the submatrix of $L*D*L^T$.
<i>bn</i>	INTEGER. Last index of the submatrix of $L*D*L^T$.
<i>lambda</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The shift. To compute an accurate eigenvector, <i>lambda</i> should be a good approximation to an eigenvalue of $L*D*L^T$.
<i>l</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION (<i>n</i> -1). The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix L , in elements 1 to <i>n</i> -1.
<i>d</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix D .
<i>ld</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION (<i>n</i> -1). The <i>n</i> -1 elements L_i*D_i .
<i>lld</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION (<i>n</i> -1). The <i>n</i> -1 elements $L_i*L_i*D_i$.
<i>pivmin</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The minimum pivot in the Sturm sequence.
<i>gaptol</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.
<i>z</i>	REAL for slarlv DOUBLE PRECISION for dlarlv COMPLEX for clarlv

	COMPLEX*16 for <code>zlarlv</code> Array, DIMENSION (n). All entries of z must be set to 0.
<code>wantnc</code>	LOGICAL. Specifies whether <code>negcnt</code> has to be computed.
<code>r</code>	INTEGER. The twist index for the twisted factorization used to compute z . On input, $0 \leq r \leq n$. If r is input as 0, r is set to the index where $(L^*D*L^T - \text{lambda}*I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$, r is unchanged.
<code>work</code>	REAL for <code>slarlv/clarlv</code> DOUBLE PRECISION for <code>dlarlv/zlarlv</code> Workspace array, DIMENSION ($4*n$).

Output Parameters

z	REAL for <code>slarlv</code> DOUBLE PRECISION for <code>dlarlv</code> COMPLEX for <code>clarlv</code> COMPLEX*16 for <code>zlarlv</code> Array, DIMENSION (n). The (scaled) r -th column of the inverse. $z(r)$ is returned to be 1.
<code>negcnt</code>	INTEGER. If <code>wantnc</code> is <code>.TRUE.</code> then <code>negcnt</code> = the number of pivots $< \text{pivmin}$ in the matrix factorization L^*D*L^T , and <code>negcnt</code> = -1 otherwise.
<code>ztz</code>	REAL for <code>slarlv/clarlv</code> DOUBLE PRECISION for <code>dlarlv/zlarlv</code> The square of the 2-norm of z .
<code>mingma</code>	REAL for <code>slarlv/clarlv</code> DOUBLE PRECISION for <code>dlarlv/zlarlv</code> The reciprocal of the largest (in magnitude) diagonal element of the inverse of $L^*D*L^T - \text{lambda}*I$.
r	On output, r is the twist index used to compute z . Ideally, r designates the position of the maximum entry in the eigenvector.

<i>isuppz</i>	INTEGER. Array, DIMENSION (2). The support of the vector in <i>z</i> , that is, the vector <i>z</i> is nonzero only in elements <i>isuppz</i> (1) through <i>isuppz</i> (2).
<i>nrminv</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Equals $1/\sqrt{ztz}$.
<i>resid</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The residual of the FP vector. $resid = \text{ABS}(\text{mingma})/\sqrt{ztz}$.
<i>rqcorr</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The Rayleigh Quotient correction to <i>lambda</i> . $rqcorr = \text{mingma}/ztz$.

?lar2v

Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.

Syntax

```
call slar2v( n, x, y, z, incx, c, s, incc )
call dlar2v( n, x, y, z, incx, c, s, incc )
call clar2v( n, x, y, z, incx, c, s, incc )
call zlar2v( n, x, y, z, incx, c, s, incc )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?lar2v` applies a vector of real/complex plane rotations with real cosines from both sides to a sequence of 2-by-2 real symmetric or complex Hermitian matrices, defined by the elements of the vectors *x*, *y* and *z*. For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i & z_i \\ \text{conjg}(z_i) & y_i \end{bmatrix} := \begin{bmatrix} c(i) & \text{conjg}(s(i)) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i & z_i \\ \text{conjg}(z_i) & y_i \end{bmatrix} \begin{bmatrix} c(i) & -\text{conjg}(s(i)) \\ s(i) & c(i) \end{bmatrix}$$

Input Parameters

<i>n</i>	INTEGER. The number of plane rotations to be applied.
<i>x, y, z</i>	REAL for slar2v DOUBLE PRECISION for dlar2v COMPLEX for clar2v COMPLEX*16 for zlar2v Arrays, DIMENSION (1+(<i>n</i> -1)* <i>incx</i>) each. Contain the vectors <i>x</i> , <i>y</i> and <i>z</i> , respectively. For all flavors of ?lar2v, elements of <i>x</i> and <i>y</i> are assumed to be real.
<i>incx</i>	INTEGER. The increment between elements of <i>x</i> , <i>y</i> , and <i>z</i> . <i>incx</i> > 0.
<i>c</i>	REAL for slar2v/clar2v DOUBLE PRECISION for dlar2v/zlar2v Array, DIMENSION (1+(<i>n</i> -1)* <i>incc</i>). The cosines of the plane rotations.
<i>s</i>	REAL for slar2v DOUBLE PRECISION for dlar2v COMPLEX for clar2v COMPLEX*16 for zlar2v Array, DIMENSION (1+(<i>n</i> -1)* <i>incc</i>). The sines of the plane rotations.
<i>incc</i>	INTEGER. The increment between elements of <i>c</i> and <i>s</i> . <i>incc</i> > 0.

Output Parameters

<i>x, y, z</i>	Vectors <i>x</i> , <i>y</i> and <i>z</i> , containing the results of transform.
----------------	---------------------------------------------------------------------------------

?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

```
call slarf( side, m, n, v, incv, tau, c, ldc, work )
call dlarf( side, m, n, v, incv, tau, c, ldc, work )
call clarf( side, m, n, v, incv, tau, c, ldc, work )
call zlarf( side, m, n, v, incv, tau, c, ldc, work )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in the form

$$H = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then H is taken to be the unit matrix. For `clarf/zlarf`, to apply H' (the conjugate transpose of H), supply `conjg(tau)` instead of τ .

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': form H^*C If <i>side</i> = 'R': form C^*H .
<i>m</i>	INTEGER. The number of rows of the matrix C .
<i>n</i>	INTEGER. The number of columns of the matrix C .
<i>v</i>	REAL for <code>slarf</code> DOUBLE PRECISION for <code>dlarf</code> COMPLEX for <code>clarf</code> COMPLEX*16 for <code>zlarf</code> Array, DIMENSION (1 + (m-1)*abs(incv)) if <i>side</i> = 'L' or

	(1 + (n-1)*abs(<i>incv</i>)) if <i>side</i> = 'R'. The vector <i>v</i> in the representation of <i>H</i> . <i>v</i> is not used if <i>tau</i> = 0.
<i>incv</i>	INTEGER. The increment between elements of <i>v</i> . <i>incv</i> ≠ 0.
<i>tau</i>	REAL for slarf DOUBLE PRECISION for dlarf COMPLEX for clarf COMPLEX*16 for zlarf The value <i>tau</i> in the representation of <i>H</i> .
<i>c</i>	REAL for slarf DOUBLE PRECISION for dlarf COMPLEX for clarf COMPLEX*16 for zlarf Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>C</i> .
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . <i>ldc</i> ≥ max(1, <i>m</i>).
<i>work</i>	REAL for slarf DOUBLE PRECISION for dlarf COMPLEX for clarf COMPLEX*16 for zlarf Workspace array, DIMENSION (<i>n</i>) if <i>side</i> = 'L' or (<i>m</i>) if <i>side</i> = 'R'.

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by the matrix H^*C if <i>side</i> = 'L', or C^*H if <i>side</i> = 'R'.
----------	-------------------------------------------------------------------------------------------------------------

?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```
call slarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )
```

```
call dlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )
```

```
call clarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )
```

```
call zlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?larfb` applies a complex block reflector H or its transpose H' to a complex m -by- n matrix C from either left or right.

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': apply H or H' from the left If <i>side</i> = 'R': apply H or H' from the right
<i>trans</i>	CHARACTER*1. If <i>trans</i> = 'N': apply H (No transpose) If <i>trans</i> = 'C': apply H' (Conjugate transpose)
<i>direct</i>	CHARACTER*1. Indicates how H is formed from a product of elementary reflectors If <i>direct</i> = 'F': $H = H(1)*H(2)*\dots*H(k)$ (forward) If <i>direct</i> = 'B': $H = H(k)*\dots*H(2)*H(1)$ (backward)

<i>storev</i>	<p>CHARACTER*1.</p> <p>Indicates how the vectors which define the elementary reflectors are stored:</p> <p>If <i>storev</i> = 'C': Column-wise</p> <p>If <i>storev</i> = 'R': Row-wise</p>
<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> .
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. The order of the matrix <i>T</i> (equal to the number of elementary reflectors whose product defines the block reflector).
<i>v</i>	<p>REAL for slarfb</p> <p>DOUBLE PRECISION for dlarfb</p> <p>COMPLEX for clarfb</p> <p>COMPLEX*16 for zlarfb</p> <p>Array, DIMENSION</p> <p>(<i>ldv</i>, <i>k</i>) if <i>storev</i> = 'C'</p> <p>(<i>ldv</i>, <i>m</i>) if <i>storev</i> = 'R' and <i>side</i> = 'L'</p> <p>(<i>ldv</i>, <i>n</i>) if <i>storev</i> = 'R' and <i>side</i> = 'R'</p> <p>The matrix <i>v</i>.</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array <i>v</i>.</p> <p>If <i>storev</i> = 'C' and <i>side</i> = 'L', $ldv \geq \max(1, m)$;</p> <p>if <i>storev</i> = 'C' and <i>side</i> = 'R', $ldv \geq \max(1, n)$;</p> <p>if <i>storev</i> = 'R', $ldv \geq k$.</p>
<i>t</i>	<p>REAL for slarfb</p> <p>DOUBLE PRECISION for dlarfb</p> <p>COMPLEX for clarfb</p> <p>COMPLEX*16 for zlarfb</p> <p>Array, DIMENSION (<i>ldt</i>, <i>k</i>).</p> <p>Contains the triangular <i>k</i>-by-<i>k</i> matrix <i>T</i> in the representation of the block reflector.</p>
<i>LDT</i>	<p>INTEGER. The leading dimension of the array <i>t</i>.</p> <p>$ldt \geq k$.</p>
<i>c</i>	<p>REAL for slarfb</p> <p>DOUBLE PRECISION for dlarfb</p> <p>COMPLEX for clarfb</p>

COMPLEX*16 for zlarfb
 Array, DIMENSION (ldc, n).
 On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array c .
 $ldc \geq \max(1, m)$.

$work$ REAL for slarfb
 DOUBLE PRECISION for dlarfb
 COMPLEX for clarfb
 COMPLEX*16 for zlarfb
 Workspace array, DIMENSION ($ldwork, k$).

$ldwork$ INTEGER. The leading dimension of the array $work$.
 If $side = 'L'$, $ldwork \geq \max(1, n)$;
 if $side = 'R'$, $ldwork \geq \max(1, m)$.

Output Parameters

c On exit, c is overwritten by H^*C , or H'^*C , or C^*H , or C^*H' .

?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
call slarfg( n, alpha, x, incx, tau )
call dlarfg( n, alpha, x, incx, tau )
call clarfg( n, alpha, x, incx, tau )
call zlarfg( n, alpha, x, incx, tau )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?larfg` generates a real/complex elementary reflector H of order n , such that

$$H^t * \begin{bmatrix} \alpha \\ x \end{bmatrix} \begin{bmatrix} \beta \\ 0 \end{bmatrix}, H^t * H = I,$$

where α and β are scalars (with β real for all flavors), and x is an $(n-1)$ -element real/complex vector. H is represented in the form

$$H = I - \tau * \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v^t \end{bmatrix}$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that for `clarfg/zlarfg`, H is not Hermitian.

If the elements of x are all zero (and, for complex flavors, α is real), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise, $1 \leq \tau \leq 2$ (for real flavors), or

$1 \leq \text{Re}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$ (for complex flavors).

Input Parameters

n	INTEGER. The order of the elementary reflector.
α	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> COMPLEX*16 for <code>zlarfg</code> On entry, the value α .
x	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> COMPLEX*16 for <code>zlarfg</code> Array, DIMENSION $(1+(n-2)*\text{abs}(\text{incx}))$. On entry, the vector x .
incx	INTEGER. The increment between elements of x . $\text{incx} > 0$.

Output Parameters

<i>alpha</i>	On exit, it is overwritten with the value <i>beta</i> .
<i>x</i>	On exit, it is overwritten with the vector <i>v</i> .
<i>tau</i>	REAL for slarfg DOUBLE PRECISION for dlarfg COMPLEX for clarfg COMPLEX*16 for zlarfg The value <i>tau</i> .

?larft

Forms the triangular factor T of a block reflector H
 $= I - V^* T^* V^H$.

Syntax

```
call slarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call dlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call clarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call zlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?larft` forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If *direct* = 'F', $H = H(1) * H(2) * \dots * H(k)$ and T is upper triangular;

If *direct* = 'B', $H = H(k) * \dots * H(2) * H(1)$ and T is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array v , and $H = I - V^* T^* V'$.

If *storev* = 'R', the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array v , and $H = I - V'^* T^* V$.

Input Parameters

<i>direct</i>	CHARACTER*1.
---------------	--------------

	Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)
<i>storev</i>	CHARACTER*1. Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): = 'C': column-wise = 'R': row-wise.
<i>n</i>	INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	INTEGER. The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$.
<i>v</i>	REAL for slarft DOUBLE PRECISION for dlarft COMPLEX for clarft COMPLEX*16 for zlarft Array, DIMENSION (<i>ldv</i> , <i>k</i>) if <i>storev</i> = 'C' or (<i>ldv</i> , <i>n</i>) if <i>storev</i> = 'R'. The matrix V .
<i>ldv</i>	INTEGER. The leading dimension of the array v . If <i>storev</i> = 'C', $ldv \geq \max(1, n)$; if <i>storev</i> = 'R', $ldv \geq k$.
<i>tau</i>	REAL for slarft DOUBLE PRECISION for dlarft COMPLEX for clarft COMPLEX*16 for zlarft Array, DIMENSION (<i>k</i>). <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$.
<i>ldt</i>	INTEGER. The leading dimension of the output array t . $ldt \geq k$.

Output Parameters

<i>t</i>	REAL for slarft
----------	-----------------

DOUBLE PRECISION for dlarft

COMPLEX for clarft

COMPLEX*16 for zlarft

Array, DIMENSION (ldt, k). The k -by- k triangular factor T of the block reflector. If $direct = 'F'$, T is upper triangular; if $direct = 'B'$, T is lower triangular. The rest of the array is not used.

v

The matrix v .

Application Notes

The shape of the matrix v and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

$direct = 'F'$ and $storev = 'C'$: $direct = 'F'$ and $storev = 'R'$:

$$\begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

$$\begin{bmatrix} 1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & v_2 & v_2 & v_2 \\ & & 1 & v_3 & v_3 \end{bmatrix}$$

direct = 'B' and storev = 'C': *direct = 'B' and storev = 'R':*

$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ & 1 & v_3 \\ & & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 & v_1 & 1 & & \\ v_2 & v_2 & v_2 & 1 & \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

?larfx

Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order less than or equal to 10.

Syntax

```
call slarfx( side, m, n, v, tau, c, ldc, work )
call dlarfx( side, m, n, v, tau, c, ldc, work )
call clarfx( side, m, n, v, tau, c, ldc, work )
call zlarfx( side, m, n, v, tau, c, ldc, work )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?larfx applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right.

H is represented in the form

$H = I - \tau v v'$, where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then H is taken to be the unit matrix

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': form H^*C If <i>side</i> = 'R': form C^*H .
<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> .
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> .
<i>v</i>	REAL for slarfx DOUBLE PRECISION for dlarfx COMPLEX for clarfx COMPLEX*16 for zlarfx Array, DIMENSION (<i>m</i>) if <i>side</i> = 'L' or (<i>n</i>) if <i>side</i> = 'R'. The vector <i>v</i> in the representation of <i>H</i> .
<i>tau</i>	REAL for slarfx DOUBLE PRECISION for dlarfx COMPLEX for clarfx COMPLEX*16 for zlarfx The value <i>tau</i> in the representation of <i>H</i> .
<i>c</i>	REAL for slarfx DOUBLE PRECISION for dlarfx COMPLEX for clarfx COMPLEX*16 for zlarfx Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>C</i> .
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . $lda \geq (1,m)$.
<i>work</i>	REAL for slarfx DOUBLE PRECISION for dlarfx COMPLEX for clarfx COMPLEX*16 for zlarfx Workspace array, DIMENSION (<i>n</i>) if <i>side</i> = 'L' or (<i>m</i>) if <i>side</i> = 'R'. <i>work</i> is not referenced if <i>H</i> has order < 11.

Output Parameters

c On exit, *c* is overwritten by the matrix H^*C if *side* = 'L', or C^*H if *side* = 'R'.

?largv

Generates a vector of plane rotations with real cosines and real/complex sines.

Syntax

```
call slargv( n, x, incx, y, incy, c, incc )
call dlargv( n, x, incx, y, incy, c, incc )
call clargv( n, x, incx, y, incy, c, incc )
call zlargv( n, x, incx, y, incy, c, incc )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine generates a vector of real/complex plane rotations with real cosines, determined by elements of the real/complex vectors *x* and *y*.

For `slargv/dlargv`:

$$\begin{bmatrix} c(i) & s(i) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} a_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

For `clargv/zlargv`:

$$\begin{bmatrix} c(i) & s(i) \\ -\text{conjg}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} r_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

where $c(i)^2 + \text{abs}(s(i))^2 = 1$ and the following conventions are used (these are the same as in `clartg/zlartg` but differ from the BLAS Level 1 routine `crotg/zrotg`):

If $y_i = 0$, then $c(i) = 1$ and $s(i) = 0$;

If $x_i = 0$, then $c(i) = 0$ and $s(i)$ is chosen so that r_i is real.

Input Parameters

n	INTEGER. The number of plane rotations to be generated.
x, y	REAL for <code>slargv</code> DOUBLE PRECISION for <code>dlargv</code> COMPLEX for <code>clargv</code> COMPLEX*16 for <code>zlargv</code> Arrays, DIMENSION $(1+(n-1)*incx)$ and $(1+(n-1)*incy)$, respectively. On entry, the vectors x and y .
$incx$	INTEGER. The increment between elements of x . $incx > 0$.
$incy$	INTEGER. The increment between elements of y . $incy > 0$.
$incc$	INTEGER. The increment between elements of the output array c . $incc > 0$.

Output Parameters

x	On exit, $x(i)$ is overwritten by a_i (for real flavors), or by r_i (for complex flavors), for $i = 1, \dots, n$.
y	On exit, the sines $s(i)$ of the plane rotations.
c	REAL for <code>slargv/clargv</code> DOUBLE PRECISION for <code>dlargv/zlargv</code> Array, DIMENSION $(1+(n-1)*incc)$. The cosines of the plane rotations.

?larnv

Returns a vector of random numbers from a uniform or normal distribution.

Syntax

```
call slarnv( idist, iseed, n, x )
call dlarnv( idist, iseed, n, x )
call clarnv( idist, iseed, n, x )
call zlarnv( idist, iseed, n, x )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?larnv returns a vector of n random real/complex numbers from a uniform or normal distribution.

This routine calls the auxiliary routine ?laruv to generate random real numbers from a uniform (0,1) distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform numbers from a uniform to a normal distribution.

Input Parameters

<i>idist</i>	<p>INTEGER. Specifies the distribution of the random numbers:</p> <p>for slarnv and dlarnv:</p> <ul style="list-style-type: none"> = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). <p>for clarnv and zlarnv:</p> <ul style="list-style-type: none"> = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $\text{abs}(z) < 1$ = 5: uniformly distributed on the circle $\text{abs}(z) = 1$
<i>iseed</i>	<p>INTEGER. Array, DIMENSION (4).</p> <p>On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i>(4) must be odd.</p>

n INTEGER. The number of random numbers to be generated.

Output Parameters

x REAL for slarnv
 DOUBLE PRECISION for dlarnv
 COMPLEX for clarnv
 COMPLEX*16 for zlarnv
 Array, DIMENSION (*n*). The generated random numbers.

iseed On exit, the seed is updated.

?larra

Computes the splitting points with the specified threshold.

Syntax

```
call slarra( n, d, e, e2, spltol, tnrm, nsplit, isplit, info )
call dlarra( n, d, e, e2, spltol, tnrm, nsplit, isplit, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the splitting points with the specified threshold and sets any "small" off-diagonal elements to zero.

Input Parameters

n INTEGER. The order of the matrix ($n > 1$).

d REAL for slarra
 DOUBLE PRECISION for dlarra
 Array, DIMENSION (*n*).
 Contains *n* diagonal elements of the tridiagonal matrix *T*.

e REAL for slarra
 DOUBLE PRECISION for dlarra
 Array, DIMENSION (*n*).

	First $(n-1)$ entries contain the subdiagonal elements of the tridiagonal matrix T ; $e(n)$ need not be set.
<i>e2</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (n). First $(n-1)$ entries contain the squares of the subdiagonal elements of the tridiagonal matrix T ; $e2(n)$ need not be set.
<i>spltol</i>	REAL for slarra DOUBLE PRECISION for dlarra The threshold for splitting. Two criteria can be used: $spltol < 0$: criterion based on absolute off-diagonal value; $spltol > 0$: criterion that preserves relative accuracy.
<i>tnrm</i>	REAL for slarra DOUBLE PRECISION for dlarra The norm of the matrix.

Output Parameters

<i>e</i>	On exit, the entries $e(isplit(i))$, $1 \leq i \leq nsplit$, are set to zero, the other entries of e are untouched.
<i>e2</i>	On exit, the entries $e2(isplit(i))$, $1 \leq i \leq nsplit$, are set to zero.
<i>nsplit</i>	INTEGER. The number of blocks the matrix T splits into. $1 \leq nsplit \leq n$
<i>isplit</i>	INTEGER. Array, DIMENSION (n). The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, and so on, and the $nsplit$ -th consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$.
<i>info</i>	INTEGER. = 0: successful exit.

zlarrb

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

```
call slarrb( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr,
work, iwork, pivmin, spdiam, twist, info )
```

```
call dlarrb( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr,
work, iwork, pivmin, spdiam, twist, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

Given the relatively robust representation (RRR) $L^*D^*L^T$, the routine does “limited” bisection to refine the eigenvalues of $L^*D^*L^T$, $w(\text{ifirst}-\text{offset})$ through $w(\text{ilast}-\text{offset})$, to more accuracy. Initial guesses for these eigenvalues are input in w . The corresponding estimate of the error in these guesses and their gaps are input in $werr$ and $wgap$, respectively. During bisection, intervals $[left, right]$ are maintained by storing their mid-points and semi-widths in the arrays w and $werr$ respectively.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix.
<i>d</i>	REAL for <code>slarrb</code> DOUBLE PRECISION for <code>dlarrb</code> Array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>lld</i>	REAL for <code>slarrb</code> DOUBLE PRECISION for <code>dlarrb</code> Array, DIMENSION (<i>n</i> -1). The <i>n</i> -1 elements $L_i^*L_i^*D_i$.
<i>ifirst</i>	INTEGER. The index of the first eigenvalue to be computed.
<i>ilast</i>	INTEGER. The index of the last eigenvalue to be computed.
<i>rtol1, rtol2</i>	REAL for <code>slarrb</code> DOUBLE PRECISION for <code>dlarrb</code>

	<p>Tolerance for the convergence of the bisection intervals. An interval $[left, right]$ has converged if $RIGHT-LEFT.LT.MAX(rtol1*gap, rtol2*max(left , right))$, where gap is the (estimated) distance to the nearest eigenvalue.</p>
<i>offset</i>	<p>INTEGER. Offset for the arrays w, $wgap$ and $werr$, that is, the <i>ifirst-offset</i> through <i>ilast-offset</i> elements of these arrays are to be used.</p>
<i>w</i>	<p>REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (n). On input, $w(ifirst-offset)$ through $w(ilast-offset)$ are estimates of the eigenvalues of $L*D*L^T$ indexed <i>ifirst</i> through <i>ilast</i>.</p>
<i>wgap</i>	<p>REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION ($n-1$). The estimated gaps between consecutive eigenvalues of $L*D*L^T$, that is, $wgap(i-offset)$ is the gap between eigenvalues i and $i+1$. Note that if $IFIRST.EQ.ILAST$ then $wgap(ifirst-offset)$ must be set to 0.</p>
<i>werr</i>	<p>REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (n). On input, $werr(ifirst-offset)$ through $werr(ilast-offset)$ are the errors in the estimates of the corresponding elements in w.</p>
<i>work</i>	<p>REAL for slarrb DOUBLE PRECISION for dlarrb Workspace array, DIMENSION ($2*n$).</p>
<i>pivmin</i>	<p>REAL for slarrb DOUBLE PRECISION for dlarrb The minimum pivot in the Sturm sequence.</p>
<i>spdiam</i>	<p>REAL for slarrb DOUBLE PRECISION for dlarrb The spectral diameter of the matrix.</p>
<i>twist</i>	<p>INTEGER. The twist index for the twisted factorization that is used for the negcount.</p>

$twist = n$: Compute negcount from $L^*D^*L^T - \lambda i$
 $= L_+^* D_+^* L_+^T$

$twist = n$: Compute negcount from $L^*D^*L^T - \lambda i$
 $= U_-^* D_-^* U_-^T$

$twist = n$: Compute negcount from $L^*D^*L^T - \lambda i$
 $= N_r^* D_r^* N_r$

iwork

INTEGER.

Workspace array, DIMENSION (2*n).

Output Parameters

w

On output, the estimates of the eigenvalues are "refined".

wgap

On output, the gaps are refined.

werr

On output, "refined" errors in the estimates of *w*.

info

INTEGER.

Error flag.

?larrc

Computes the number of eigenvalues of the symmetric tridiagonal matrix.

Syntax

call slarrc(jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info)

call dlarrc(jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info)

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine finds the number of eigenvalues of the symmetric tridiagonal matrix T or of its factorization $L^*D^*L^T$ in the specified interval.

Input Parameters

jobt

CHARACTER*1.

	= 'T': computes Sturm count for matrix T .
	= 'L': computes Sturm count for matrix $L^*D^*L^T$.
n	INTEGER. The order of the matrix. ($n > 1$).
vl, vu	REAL for slarrc DOUBLE PRECISION for dlarrc The lower and upper bounds for the eigenvalues.
d	REAL for slarrc DOUBLE PRECISION for dlarrc Array, DIMENSION (n). If $jobt = 'T'$: contains the n diagonal elements of the tridiagonal matrix T . If $jobt = 'L'$: contains the n diagonal elements of the diagonal matrix D .
e	REAL for slarrc DOUBLE PRECISION for dlarrc Array, DIMENSION (n). If $jobt = 'T'$: contains the $(n-1)$ offdiagonal elements of the matrix T . If $jobt = 'L'$: contains the $(n-1)$ offdiagonal elements of the matrix L .
$pivmin$	REAL for slarrc DOUBLE PRECISION for dlarrc The minimum pivot in the Sturm sequence for the matrix T .

Output Parameters

$eigcnt$	INTEGER. The number of eigenvalues of the symmetric tridiagonal matrix T that are in the half-open interval $(vl, vu]$.
$lcnt, rcnt$	INTEGER. The left and right negcounts of the interval.
$info$	INTEGER. Now it is not used and always is set to 0.

?larrrd

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

```
call slarrrd( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin,
             nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info )

call dlarrrd( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin,
             nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the eigenvalues of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from `?stemr`. The user may ask for all eigenvalues, all eigenvalues in the half-open interval $(vl, vu]$, or the il -th through iu -th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. (For more details see [Kahan66].

Input Parameters

<i>range</i>	CHARACTER. = 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval $(vl, vu]$ will be found. = 'I': ("Index") the il -th through iu -th eigenvalues will be found.
<i>order</i>	CHARACTER. = 'B': ("By block") the eigenvalues will be grouped by split-off block (see <i>iblock</i> , <i>isplit</i> below) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.
<i>n</i>	INTEGER. The order of the tridiagonal matrix T ($n \geq 1$).

<i>vl,vu</i>	<p>REAL for slarrd DOUBLE PRECISION for dlarrrd If <i>range</i> = 'V': the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to <i>vl</i>, or greater than <i>vu</i>, will not be returned. $vl < vu$. If <i>range</i> = 'A' or 'I': not referenced.</p>
<i>il,iu</i>	<p>INTEGER. If <i>range</i> = 'I': the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n=0$. If <i>range</i> = 'A' or 'V': not referenced.</p>
<i>gers</i>	<p>REAL for slarrd DOUBLE PRECISION for dlarrrd Array, DIMENSION (2*n). The <i>n</i> Gerschgorin intervals (the <i>i</i>-th Gerschgorin interval is (<i>gers</i>(2*i-1), <i>gers</i>(2*i))).</p>
<i>reltol</i>	<p>REAL for slarrd DOUBLE PRECISION for dlarrrd The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least <i>radix*machine epsilon</i>.</p>
<i>d</i>	<p>REAL for slarrd DOUBLE PRECISION for dlarrrd Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>.</p>
<i>e</i>	<p>REAL for slarrd DOUBLE PRECISION for dlarrrd Array, DIMENSION (<i>n</i>-1). Contains (<i>n</i>-1) off-diagonal elements of the tridiagonal matrix <i>T</i>.</p>
<i>e2</i>	<p>REAL for slarrd DOUBLE PRECISION for dlarrrd Array, DIMENSION (<i>n</i>-1).</p>

	Contains $(n-1)$ squared off-diagonal elements of the tridiagonal matrix T .
<i>pivmin</i>	REAL for slarrd DOUBLE PRECISION for dlarrd The minimum pivot in the Sturm sequence for the matrix T .
<i>nsplit</i>	INTEGER. The number of diagonal blocks the matrix T . $1 \leq nsplit \leq n$
<i>isplit</i>	INTEGER. Arrays, DIMENSION (n) . The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), and so on, and the <i>nsplit</i> -th consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= n . (Only the first <i>nsplit</i> elements actually is used, but since the user cannot know a priori value of <i>nsplit</i> , n words must be reserved for <i>isplit</i> .)
<i>work</i>	REAL for slarrd DOUBLE PRECISION for dlarrd Workspace array, DIMENSION $(4*n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION $(4*n)$.

Output Parameters

<i>m</i>	INTEGER. The actual number of eigenvalues found. $0 \leq m \leq n$. (See also the description of <i>info</i> =2,3.)
<i>w</i>	REAL for slarrd DOUBLE PRECISION for dlarrd Array, DIMENSION (n) .

The first m elements of w contain the eigenvalue approximations. `?laprd` computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue j . The eigenvalue approximation is given as the interval midpoint $w(j) = (a_j + b_j) / 2$. The corresponding error is bounded by $werr(j) = \text{abs}(a_j - b_j) / 2$.

werr

REAL for `slarrd`
DOUBLE PRECISION for `dlarrd`
Array, DIMENSION (n).

The error bound on the corresponding eigenvalue approximation in w .

wl, wu

REAL for `slarrd`
DOUBLE PRECISION for `dlarrd`

The interval $(wl, wu]$ contains all the wanted eigenvalues.

If *range* = 'V': then $wl=v_l$ and $wu=v_u$.

If *range* = 'A': then wl and wu are the global Gerschgorin bounds on the spectrum.

If *range* = 'I': then wl and wu are computed by `?laebz` from the index range specified.

iblock

INTEGER.

Array, DIMENSION (n).

At each row/column j where $e(j)$ is zero or small, the matrix T is considered to split into a block diagonal matrix.

If *info* = 0, then *iblock*(i) specifies to which block (from 1 to the number of blocks) the eigenvalue $w(i)$ belongs.

(The routine may use the remaining $n-m$ elements as workspace.)

indexw

INTEGER.

Array, DIMENSION (n).

The indices of the eigenvalues within each block (submatrix); for example, *indexw*(i) = j and *iblock*(i) = k imply that the i -th eigenvalue $w(i)$ is the j -th eigenvalue in block k .

info

INTEGER.

= 0: successful exit.

< 0: if *info* = $-i$, the i -th argument has an illegal value

> 0: some or all of the eigenvalues fail to converge or are not computed:

=1 or 3: bisection fail to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

=2 or 3: *range*='I' only: not all of the eigenvalues *il:iu* are found.

=4: *range*='I', and the Gershgorin interval initially used is too small. No eigenvalues are computed.

?larre

Given the tridiagonal matrix T , sets small off-diagonal elements to zero and for each unreduced block T_i , finds base representations and eigenvalues.

Syntax

```
call slarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit,
            isplit, m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
call dlarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit,
            isplit, m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , the routine sets any “small” off-diagonal elements to zero, and for each unreduced block T_i , it finds

- a suitable shift at one end of the block spectrum
- the base representation, $T_i - \sigma_i * I = L_i * D_i * L_i^T$, and
- eigenvalues of each $L_i * D_i * L_i^T$.

The representations and eigenvalues found are then used by `?stemr` to compute the eigenvectors of a symmetric tridiagonal matrix. The accuracy varies depending on whether bisection is used to find a few eigenvalues or the `dqds` algorithm (subroutine `?lasq2`) to compute all and discard any unwanted one. As an added benefit, `?larre` also outputs the n Gerschgorin intervals for the matrices $L_i * D_i * L_i^T$.

Input Parameters

<i>range</i>	<p>CHARACTER.</p> <p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval (<i>vl</i>, <i>vu</i>] will be found.</p> <p>= 'I': ("Index") the <i>il</i>-th through <i>iu</i>-th eigenvalues of the entire matrix will be found.</p>
<i>n</i>	INTEGER. The order of the matrix. $n > 0$.
<i>vl</i> , <i>vu</i>	<p>REAL for slarre</p> <p>DOUBLE PRECISION for dlarre</p> <p>If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i>, or greater than <i>vu</i>, are not returned. $vl < vu$.</p>
<i>il</i> , <i>iu</i>	<p>INTEGER.</p> <p>If <i>range</i>='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$.</p>
<i>d</i>	<p>REAL for slarre</p> <p>DOUBLE PRECISION for dlarre</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>The <i>n</i> diagonal elements of the diagonal matrices <i>T</i>.</p>
<i>e</i>	<p>REAL for slarre</p> <p>DOUBLE PRECISION for dlarre</p> <p>Array, DIMENSION (<i>n</i>). The first (<i>n</i>-1) entries contain the subdiagonal elements of the tridiagonal matrix <i>T</i>; <i>e</i>(<i>n</i>) need not be set.</p>
<i>e2</i>	<p>REAL for slarre</p> <p>DOUBLE PRECISION for dlarre</p> <p>Array, DIMENSION (<i>n</i>). The first (<i>n</i>-1) entries contain the squares of the subdiagonal elements of the tridiagonal matrix <i>T</i>; <i>e2</i>(<i>n</i>) need not be set.</p>
<i>rtol1</i> , <i>rtol2</i>	<p>REAL for slarre</p> <p>DOUBLE PRECISION for dlarre</p>

Parameters for bisection. An interval $[LEFT, RIGHT]$ has converged if $RIGHT-LEFT.LT.MAX(rtol1*gap, rtol2*\max(|LEFT|, |RIGHT|))$.

spltol REAL for slarre
DOUBLE PRECISION for dlarre
The threshold for splitting.

work REAL for slarre
DOUBLE PRECISION for dlarre
Workspace array, DIMENSION $(6*n)$.

iwork INTEGER.
Workspace array, DIMENSION $(5*n)$.

Output Parameters

vl, vu On exit, if *range*='I' or 'A', contain the bounds on the desired part of the spectrum.

d On exit, the n diagonal elements of the diagonal matrices D_i .

e On exit, the subdiagonal elements of the unit bidiagonal matrices L_i . The entries $e(isplit(i))$, $1 \leq i \leq nsplit$, contain the base points σ_{α_i} on output.

e2 On exit, the entries $e2(isplit(i))$, $1 \leq i \leq nsplit$, have been set to zero.

nsplit INTEGER. The number of blocks T splits into. $1 \leq nsplit \leq n$.

isplit INTEGER. Array, DIMENSION (n) . The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, etc., and the $nsplit$ -th consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$.

m INTEGER. The total number of eigenvalues (of all the $L_i * D_i * L_i^T$) found.

w REAL for slarre
DOUBLE PRECISION for dlarre

	<p>Array, DIMENSION (n). The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i * D_i * L_i^T$, are sorted in ascending order. The routine may use the remaining $n-m$ elements as workspace.</p>
<i>werr</i>	<p>REAL for slarre DOUBLE PRECISION for dlarre</p> <p>Array, DIMENSION (n). The error bound on the corresponding eigenvalue in w.</p>
<i>wgap</i>	<p>REAL for slarre DOUBLE PRECISION for dlarre</p> <p>Array, DIMENSION (n). The separation from the right neighbor eigenvalue in w. The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block the left gap is stored.</p>
<i>iblock</i>	<p>INTEGER. Array, DIMENSION (n).</p> <p>The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w; $iblock(i)=1$ if eigenvalue $w(i)$ belongs to the first block from the top, $=2$ if $w(i)$ belongs to the second block, etc.</p>
<i>indexw</i>	<p>INTEGER. Array, DIMENSION (n).</p> <p>The indices of the eigenvalues within each block (submatrix); for example, $indexw(i)=10$ and $iblock(i)=2$ imply that the i-th eigenvalue $w(i)$ is the 10-th eigenvalue in the second block.</p>
<i>gers</i>	<p>REAL for slarre DOUBLE PRECISION for dlarre</p> <p>Array, DIMENSION ($2*n$). The n Gerschgorin intervals (the i-th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$).</p>
<i>pivmin</i>	<p>REAL for slarre DOUBLE PRECISION for dlarre</p> <p>The minimum pivot in the Sturm sequence for T.</p>
<i>info</i>	<p>INTEGER.</p> <p>If $info = 0$: successful exit If $info > 0$: A problem occurred in ?larre. If $info = 5$, the Rayleigh Quotient Iteration failed to converge to full accuracy.</p>

If $info < 0$: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter $info$ for further information is required.

- If $info = -1$, there is a problem in `?larrrd`
- If $info = -2$, no base representation could be found in `maxtry` iterations. Increasing `maxtry` and recompilation might be a remedy.
- If $info = -3$, there is a problem in `?larrrb` when computing the refined root representation for `?lasq2`.
- If $info = -4$, there is a problem in `?larrrb` when performing bisection on the desired part of the spectrum.
- If $info = -5$, there is a problem in `?lasq2`.
- If $info = -6$, there is a problem in `?lasq2`.

?larrrf

Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.

Syntax

```
call slarrrf( n, d, l, ld, clstrt, clend, w, wgap, werr, spdiam, clgapl, clgapr,
             pivmin, sigma, dplus, lplus, work, info )
```

```
call dlarrrf( n, d, l, ld, clstrt, clend, w, wgap, werr, spdiam, clgapl, clgapr,
             pivmin, sigma, dplus, lplus, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

Given the initial representation $L*D*L^T$ and its cluster of close eigenvalues (in a relative measure), $w(clstrt), w(clstrt+1), \dots, w(clend)$, the routine `?larrf` finds a new relatively robust representation

$$L*D*L^T - \sigma_i * I = L(+)*D(+)*L(+)^T$$

such that at least one of the eigenvalues of $L(+)*D(+)*L(+)^T$ is relatively isolated.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix (subblock, if the matrix is splitted).
<i>d</i>	REAL for <code>slarrf</code> DOUBLE PRECISION for <code>dlarrf</code> Array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>l</i>	REAL for <code>slarrf</code> DOUBLE PRECISION for <code>dlarrf</code> Array, DIMENSION (<i>n</i> -1). The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> .
<i>ld</i>	REAL for <code>slarrf</code> DOUBLE PRECISION for <code>dlarrf</code> Array, DIMENSION (<i>n</i> -1). The <i>n</i> -1 elements $L_i * D_i$.
<i>clstrt</i>	INTEGER. The index of the first eigenvalue in the cluster.
<i>clend</i>	INTEGER. The index of the last eigenvalue in the cluster.
<i>w</i>	REAL for <code>slarrf</code> DOUBLE PRECISION for <code>dlarrf</code> Array, DIMENSION $\geq (clend - clstrt + 1)$. The eigenvalue approximations of $L*D*L^T$ in ascending order. $w(clstrt)$ through $w(clend)$ form the cluster of relatively close eigenvalues.
<i>wgap</i>	REAL for <code>slarrf</code>

	DOUBLE PRECISION for dlarrf
	Array, DIMENSION $\geq (clend-clstrt+1)$. The separation from the right neighbor eigenvalue in w .
<i>werr</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf
	Array, DIMENSION $\geq (clend-clstrt+1)$. On input, <i>werr</i> contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in w .
<i>spdiam</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf
	Estimate of the spectral diameter obtained from the Gerschgorin intervals.
<i>clgapl, clgapr</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf
	Absolute gap on each end of the cluster. Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.
<i>pivmin</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf
	The minimum pivot allowed in the Sturm sequence.
<i>work</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf
	Workspace array, DIMENSION $(2*n)$.

Output Parameters

<i>wgap</i>	On output, the gaps are refined.
<i>sigma</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf
	The shift used to form $L(+) * D^*(+) * L(+)^T$.
<i>dplus</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf
	Array, DIMENSION (n) . The n diagonal elements of the diagonal matrix $D(+)$.
<i>lplus</i>	REAL for slarrf
	DOUBLE PRECISION for dlarrf

Array, DIMENSION (n). The first ($n-1$) elements of $lplus$ contain the subdiagonal elements of the unit bidiagonal matrix $L(+)$.

?larrj

Performs refinement of the initial estimates of the eigenvalues of the matrix T .

Syntax

```
call slarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork,
pivmin, spdiam, info )
```

```
call dlarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork,
pivmin, spdiam, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

Given the initial eigenvalue approximations of T , this routine does bisection to refine the eigenvalues of T , $w(ifirst-offset)$ through $w(ilast-offset)$, to more accuracy. Initial guesses for these eigenvalues are input in w , the corresponding estimate of the error in these guesses in $werr$. During bisection, intervals $[a,b]$ are maintained by storing their mid-points and semi-widths in the arrays w and $werr$ respectively.

Input Parameters

n	INTEGER. The order of the matrix T .
d	REAL for <code>slarrj</code> DOUBLE PRECISION for <code>dlarrj</code> Array, DIMENSION (n). Contains n diagonal elements of the matrix T .
$e2$	REAL for <code>slarrj</code> DOUBLE PRECISION for <code>dlarrj</code> Array, DIMENSION ($n-1$). Contains ($n-1$) squared sub-diagonal elements of the T .
$ifirst$	INTEGER. The index of the first eigenvalue to be computed.

<i>ilast</i>	<p>INTEGER.</p> <p>The index of the last eigenvalue to be computed.</p>
<i>rtol</i>	<p>REAL for slarrj DOUBLE PRECISION for dlarrj</p> <p>Tolerance for the convergence of the bisection intervals. An interval $[a,b]$ is considered to be converged if $(b-a) \leq rtol * \max(a , b)$.</p>
<i>offset</i>	<p>INTEGER.</p> <p>Offset for the arrays <i>w</i> and <i>werr</i>, that is the <i>ifirst</i>-<i>offset</i> through <i>ilast</i>-<i>offset</i> elements of these arrays are to be used.</p>
<i>w</i>	<p>REAL for slarrj DOUBLE PRECISION for dlarrj</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>On input, <i>w</i>(<i>ifirst</i>-<i>offset</i>) through <i>w</i>(<i>ilast</i>-<i>offset</i>) are estimates of the eigenvalues of L^*D*L^T indexed <i>ifirst</i> through <i>ilast</i>.</p>
<i>werr</i>	<p>REAL for slarrj DOUBLE PRECISION for dlarrj</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>On input, <i>werr</i>(<i>ifirst</i>-<i>offset</i>) through <i>werr</i>(<i>ilast</i>-<i>offset</i>) are the errors in the estimates of the corresponding elements in <i>w</i>.</p>
<i>work</i>	<p>REAL for slarrj DOUBLE PRECISION for dlarrj</p> <p>Workspace array, DIMENSION ($2*n$).</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION ($2*n$).</p>
<i>pivmin</i>	<p>REAL for slarrj DOUBLE PRECISION for dlarrj</p> <p>The minimum pivot in the Sturm sequence for the matrix <i>T</i>.</p>
<i>spdiam</i>	<p>REAL for slarrj DOUBLE PRECISION for dlarrj</p> <p>The spectral diameter of the matrix <i>T</i>.</p>

Output Parameters

<i>w</i>	On exit, contains the refined estimates of the eigenvalues.
<i>werr</i>	On exit, contains the refined errors in the estimates of the corresponding elements in <i>w</i> .
<i>info</i>	INTEGER. Now it is not used and always is set to 0.

?larrk

Computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy.

Syntax

```
call slarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
call dlarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from `?stemr`.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. For more details see [Kahan66].

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T . ($n \geq 1$).
<i>iw</i>	INTEGER. The index of the eigenvalue to be returned.
<i>gl, gu</i>	REAL for <code>slarrk</code> DOUBLE PRECISION for <code>dlarrk</code> An upper and a lower bound on the eigenvalue.
<i>d</i>	REAL for <code>slarrk</code> DOUBLE PRECISION for <code>dlarrk</code>

	Array, DIMENSION (n). Contains n diagonal elements of the matrix T .
<i>e2</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Array, DIMENSION ($n-1$). Contains ($n-1$) squared off-diagonal elements of the T .
<i>pivmin</i>	REAL for slarrk DOUBLE PRECISION for dlarrk The minimum pivot in the Sturm sequence for the matrix T .
<i>reltol</i>	REAL for slarrk DOUBLE PRECISION for dlarrk The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least <i>radix*machine epsilon</i> .

Output Parameters

<i>w</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Contains the eigenvalue approximation.
<i>werr</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Contains the error bound on the corresponding eigenvalue approximation in <i>w</i> .
<i>info</i>	INTEGER. = 0: Eigenvalue converges = -1: Eigenvalue does not converge

?larr

Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Syntax

```
call slarr( n, d, e, info )
call dlarr( n, d, e, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Input Parameters

n	INTEGER. The order of the matrix T . ($n > 0$).
d	REAL for <code>slarr</code> DOUBLE PRECISION for <code>dlarr</code> Array, DIMENSION (n). Contains n diagonal elements of the matrix T .
e	REAL for <code>slarr</code> DOUBLE PRECISION for <code>dlarr</code> Array, DIMENSION (n). The first $(n-1)$ entries contain sub-diagonal elements of the tridiagonal matrix T ; $e(n)$ is set to 0.

Output Parameters

$info$	INTEGER. = 0: the matrix warrants computations preserving relative accuracy (default value). = -1: the matrix warrants computations guaranteeing only absolute accuracy.
--------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

?larrv

Computes the eigenvectors of the tridiagonal matrix $T = L^ D^* L^T$ given L , D and the eigenvalues of $L^* D^* L^T$.*

Syntax

```
call slarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )

call dlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )

call clarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )

call zlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?larrv computes the eigenvectors of the tridiagonal matrix $T = L^* D^* L^T$ given L , D and approximations to the eigenvalues of $L^* D^* L^T$.

The input eigenvalues should have been computed by slarre for real flavors (slarrv/clarrv) and by dlarre for double precision flavors (dlarrv/zlarrv).

Input Parameters

n	INTEGER. The order of the matrix. $n \geq 0$.
vl, vu	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv

	<p>Lower and upper bounds respectively of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range.</p>
<i>d</i>	<p>REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). On entry, the <i>n</i> diagonal elements of the diagonal matrix <i>D</i>.</p>
<i>l</i>	<p>REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). On entry, the (<i>n</i>-1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> are contained in elements 1 to <i>n</i>-1 of <i>L</i> if the matrix is not splitted. At the end of each block the corresponding shift is stored as given by slarre for real flavors and by dlarre for double precision flavors.</p>
<i>pivmin</i>	<p>REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv The minimum pivot allowed in the Sturm sequence.</p>
<i>isplit</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>). The splitting points, at which <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i>(1), the second of rows/columns <i>isplit</i>(1)+1 through <i>isplit</i>(2), etc.</p>
<i>m</i>	<p>INTEGER. The total number of eigenvalues found. $0 \leq m \leq n$. If <i>range</i> = 'A', <i>m</i> = <i>n</i>, and if <i>range</i> = 'I', <i>m</i> = <i>iu</i> - <i>il</i> + 1.</p>
<i>dol, dou</i>	<p>INTEGER. If you want to compute only selected eigenvectors from all the eigenvalues supplied, specify an index range <i>dol</i>:<i>dou</i>. Or else apply the setting <i>dol</i>=1, <i>dou</i>=<i>m</i>. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i>. If you want to compute only selected eigenpairs, then the columns <i>dol</i>-1 to <i>dou</i>+1 of the eigenvector space <i>Z</i> contain the computed eigenvectors. All other columns of <i>Z</i> are set to zero.</p>

minrgp, rtol1, rtol2 REAL for slarrv/clarrv
DOUBLE PRECISION for dlarrv/zlarrv
Parameters for bisection. An interval [LEFT,RIGHT] has converged if $\text{RIGHT} - \text{LEFT} \leq \text{MAX}(\text{rtol1} * \text{gap}, \text{rtol2} * \max(|\text{LEFT}|, |\text{RIGHT}|))$.

w REAL for slarrv/clarrv
DOUBLE PRECISION for dlarrv/zlarrv
Array, DIMENSION (*n*). The first *m* elements of *w* contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (the output array *w* from ?larre is expected here). These eigenvalues are set with respect to the shift of the corresponding root representation for their block.

werr REAL for slarrv/clarrv
DOUBLE PRECISION for dlarrv/zlarrv
Array, DIMENSION (*n*). The first *m* elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in *w*.

wgap REAL for slarrv/clarrv
DOUBLE PRECISION for dlarrv/zlarrv
Array, DIMENSION (*n*). The separation from the right neighbor eigenvalue in *w*.

iblock INTEGER. Array, DIMENSION (*n*).
The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*; *iblock*(*i*)=1 if eigenvalue *w*(*i*) belongs to the first block from the top, =2 if *w*(*i*) belongs to the second block, etc.

indexw INTEGER. Array, DIMENSION (*n*).
The indices of the eigenvalues within each block (submatrix); for example, *indexw*(*i*)= 10 and *iblock*(*i*)=2 imply that the *i*-th eigenvalue *w*(*i*) is the 10-th eigenvalue in the second block.

gers REAL for slarrv/clarrv
DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION (2*n). The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$). The Gerschgorin intervals should be computed from the original unshifted matrix.

ldz INTEGER. The leading dimension of the output array *z*. $ldz \geq 1$, and if *jobz* = 'V', $ldz \geq \max(1, n)$.

work REAL for slarrv/clarrv
DOUBLE PRECISION for dlarrv/zlarrv
Workspace array, DIMENSION (12*n).

iwork INTEGER.
Workspace array, DIMENSION (7*n).

Output Parameters

d On exit, *d* may be overwritten.

l On exit, *l* is overwritten.

w On exit, *w* holds the eigenvalues of the unshifted matrix.

werr On exit, *werr* contains refined values of its input approximations.

wgap On exit, *wgap* contains refined values of its input approximations. Very small gaps are changed.

z REAL for slarrv
DOUBLE PRECISION for dlarrv
COMPLEX for clarrv
COMPLEX*16 for zlarrv
Array, DIMENSION (ldz, max(1,m)).
If *info* = 0, the first m columns of *z* contain the orthonormal eigenvectors of the matrix *T* corresponding to the input eigenvalues, with the i -th column of *z* holding the eigenvector associated with $w(i)$.

NOTE. The user must ensure that at least $\max(1, m)$ columns are supplied in the array *z*.

isuppz INTEGER .

info

Array, `DIMENSION (2*max(1,m))`. The support of the eigenvectors in *z*, that is, the indices indicating the nonzero elements in *z*. The *i*-th eigenvector is nonzero only in elements *isuppz*(2*i*-1) through *isuppz*(2*i*).

INTEGER.

If *info* = 0: successful exit

If *info* > 0: A problem occurred in ?larrv. If *info* = 5, the Rayleigh Quotient Iteration failed to converge to full accuracy.

If *info* < 0: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter *info* for further information is required.

- If *info* = -1, there is a problem in ?larrb when refining a child eigenvalue;
- If *info* = -2, there is a problem in ?larrf when computing the relatively robust representation (RRR) of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter *minrgp* smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/*minrgp*, you should be aware that you might be trading in precision when you decrease *minrgp*.
- If *info* = -3, there is a problem in ?larrb when refining a single eigenvalue after the Rayleigh correction was rejected.

?lartg

Generates a plane rotation with real cosine and real/complex sine.

Syntax

```
call slartg( f, g, cs, sn, r )
call dlartg( f, g, cs, sn, r )
call clartg( f, g, cs, sn, r )
call zlartg( f, g, cs, sn, r )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -\text{conjg}(sn) & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + |sn|^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine [?rotg](#), except for the following differences.

For `slartg/dlartg`:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$ and $g \neq 0$, then $cs=0$ and $sn=1$ without doing any floating point operations (saves work in `?bdsqr` when there are zeros on the diagonal);

If f exceeds g in magnitude, cs will be positive.

For `clartg/zlartg`:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$, then $cs=0$ and sn is chosen so that r is real.

Input Parameters

f, g REAL for slartg
 DOUBLE PRECISION for dlartg
 COMPLEX for clartg
 COMPLEX*16 for zlartg
 The first and second component of vector to be rotated.

Output Parameters

cs REAL for slartg/clartg
 DOUBLE PRECISION for dlartg/zlartg
 The cosine of the rotation.

sn REAL for slartg
 DOUBLE PRECISION for dlartg
 COMPLEX for clartg
 COMPLEX*16 for zlartg
 The sine of the rotation.

r REAL for slartg
 DOUBLE PRECISION for dlartg
 COMPLEX for clartg
 COMPLEX*16 for zlartg
 The nonzero component of the rotated vector.

?lartv

Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.

Syntax

```
call slartv( n, x, incx, y, incy, c, s, incc )
call dlartv( n, x, incx, y, incy, c, s, incc )
call clartv( n, x, incx, y, incy, c, s, incc )
call zlartv( n, x, incx, y, incy, c, s, incc )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine applies a vector of real/complex plane rotations with real cosines to elements of the real/complex vectors `x` and `y`. For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} := \begin{bmatrix} c(i) & s(i) \\ -\text{conjg}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix}$$

Input Parameters

<code>n</code>	INTEGER. The number of plane rotations to be applied.
<code>x, y</code>	REAL for <code>slartv</code> DOUBLE PRECISION for <code>dlartv</code> COMPLEX for <code>clartv</code> COMPLEX*16 for <code>zlartv</code> Arrays, DIMENSION $(1+(n-1)*incx)$ and $(1+(n-1)*incy)$, respectively. The input vectors <code>x</code> and <code>y</code> .
<code>incx</code>	INTEGER. The increment between elements of <code>x</code> . $incx > 0$.
<code>incy</code>	INTEGER. The increment between elements of <code>y</code> . $incy > 0$.
<code>c</code>	REAL for <code>slartv/clartv</code>

	DOUBLE PRECISION for dlartv/zlartv
	Array, DIMENSION (1+(n-1)*incc).
	The cosines of the plane rotations.
<i>s</i>	REAL for slartv
	DOUBLE PRECISION for dlartv
	COMPLEX for clartv
	COMPLEX*16 for zlartv
	Array, DIMENSION (1+(n-1)*incc).
	The sines of the plane rotations.
<i>incc</i>	INTEGER. The increment between elements of <i>c</i> and <i>s</i> . <i>incc</i>
	> 0.

Output Parameters

<i>x, y</i>	The rotated vectors <i>x</i> and <i>y</i> .
-------------	---------------------------------------------

?laruv

Returns a vector of n random real numbers from a uniform distribution.

Syntax

```
call slaruv( iseed, n, x )
call dlaruv( iseed, n, x )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?laruv returns a vector of n random real numbers from a uniform (0,1) distribution ($n \leq 128$).

This is an auxiliary routine called by ?larnv.

Input Parameters

<i>iseed</i>	INTEGER. Array, DIMENSION (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i> (4) must be odd.
--------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------

n INTEGER. The number of random numbers to be generated.
 $n \leq 128$.

Output Parameters

x REAL for slaruv
 DOUBLE PRECISION for dlaruv
 Array, DIMENSION (*n*). The generated random numbers.

seed On exit, the seed is updated.

?larz

Applies an elementary reflector (as returned by ?tzzrzf) to a general matrix.

Syntax

```
call slarz( side, m, n, l, v, incv, tau, c, ldc, work )
call dlarz( side, m, n, l, v, incv, tau, c, ldc, work )
call clarz( side, m, n, l, v, incv, tau, c, ldc, work )
call zlarz( side, m, n, l, v, incv, tau, c, ldc, work )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?larz applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in the form

$$H = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then H is taken to be the unit matrix.

For complex flavors, to apply H^H (the conjugate transpose of H), supply `conjg(tau)` instead of τ .

H is a product of k elementary reflectors as returned by ?tzzrzf.

Input Parameters

<i>side</i>	<p>CHARACTER*1. If <i>side</i> = 'L': form H^*C If <i>side</i> = 'R': form C^*H</p>
<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> .
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> .
<i>l</i>	<p>INTEGER. The number of entries of the vector <i>v</i> containing the meaningful part of the Householder vectors. If <i>side</i> = 'L', $m \geq L \geq 0$, if <i>side</i> = 'R', $n \geq L \geq 0$.</p>
<i>v</i>	<p>REAL for slarz DOUBLE PRECISION for dlarz COMPLEX for clarz COMPLEX*16 for zlarz Array, DIMENSION $(1+(l-1)*abs(incv))$. The vector <i>v</i> in the representation of H as returned by ?tzzrzf. <i>v</i> is not used if $\tau = 0$.</p>
<i>incv</i>	<p>INTEGER. The increment between elements of <i>v</i>. $incv \neq 0$.</p>
<i>tau</i>	<p>REAL for slarz DOUBLE PRECISION for dlarz COMPLEX for clarz COMPLEX*16 for zlarz The value <i>tau</i> in the representation of H.</p>
<i>c</i>	<p>REAL for slarz DOUBLE PRECISION for dlarz COMPLEX for clarz COMPLEX*16 for zlarz Array, DIMENSION (ldc,n). On entry, the m-by-n matrix <i>C</i>.</p>
<i>ldc</i>	<p>INTEGER. The leading dimension of the array <i>c</i>. $ldc \geq \max(1, m)$.</p>
<i>work</i>	REAL for slarz

DOUBLE PRECISION for dlarz
 COMPLEX for clarz
 COMPLEX*16 for zlarz
 Workspace array, DIMENSION
 (n) if side = 'L' or
 (m) if side = 'R'.

Output Parameters

c On exit, *c* is overwritten by the matrix H^*C if side = 'L',
 or C^*H if side = 'R'.

?larzb

*Applies a block reflector or its
 transpose/conjugate-transpose to a general matrix.*

Syntax

```
call slarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,
work, ldwork )

call dlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,
work, ldwork )

call clarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,
work, ldwork )

call zlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,
work, ldwork )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine applies a real/complex block reflector H or its transpose H^T (or H^H for complex flavors) to a real/complex distributed m -by- n matrix C from the left or the right. Currently, only `storev = 'R'` and `direct = 'B'` are supported.

Input Parameters

side CHARACTER*1.

If $side = 'L'$: apply H or H^T/H^H from the left
 If $side = 'R'$: apply H or H^T/H^H from the right

trans CHARACTER*1.
 If $trans = 'N'$: apply H (No transpose)
 If $trans = 'C'$: apply H^T/H^H (transpose/conjugate transpose)

direct CHARACTER*1.
 Indicates how H is formed from a product of elementary reflectors
 = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward, not supported)
 = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)

storev CHARACTER*1.
 Indicates how the vectors which define the elementary reflectors are stored:
 = 'C': Column-wise (not supported)
 = 'R': Row-wise.

m INTEGER. The number of rows of the matrix C .

n INTEGER. The number of columns of the matrix C .

k INTEGER. The order of the matrix T (equal to the number of elementary reflectors whose product defines the block reflector).

l INTEGER. The number of columns of the matrix v containing the meaningful part of the Householder reflectors.
 If $side = 'L'$, $m \geq l \geq 0$, if $side = 'R'$, $n \geq l \geq 0$.

v REAL for slarzb
 DOUBLE PRECISION for dlarzb
 COMPLEX for clarzb
 COMPLEX*16 for zlarzb
 Array, DIMENSION (ldv , nv).
 If $storev = 'C'$, $nv = k$;
 if $storev = 'R'$, $nv = l$.

ldv INTEGER. The leading dimension of the array v .
 If $storev = 'C'$, $ldv \geq l$; if $storev = 'R'$, $ldv \geq k$.

t REAL for slarzb
 DOUBLE PRECISION for dlarzb
 COMPLEX for clarzb

	COMPLEX*16 for zlarzb
	Array, DIMENSION (ldt, k). The triangular k -by- k matrix T in the representation of the block reflector.
ldt	INTEGER. The leading dimension of the array t . $ldt \geq k$.
c	REAL for slarzb DOUBLE PRECISION for dlarzb COMPLEX for clarzb COMPLEX*16 for zlarzb
	Array, DIMENSION (ldc, n). On entry, the m -by- n matrix C .
ldc	INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.
$work$	REAL for slarzb DOUBLE PRECISION for dlarzb COMPLEX for clarzb COMPLEX*16 for zlarzb
	Workspace array, DIMENSION ($ldwork, k$).
$ldwork$	INTEGER. The leading dimension of the array $work$. If $side = 'L'$, $ldwork \geq \max(1, n)$; if $side = 'R'$, $ldwork \geq \max(1, m)$.

Output Parameters

c	On exit, c is overwritten by H^*C , or $H^T/H^H * C$, or C^*H , or C^*H^T/H^H .
-----	------------------------------------------------------------------------------------------

zlazt

*Forms the triangular factor T of a block reflector H
 $= I - V^* T^H V$.*

Syntax

```
call slazt( direct, storev, n, k, v, ldv, tau, t, ldt )
call dlazt( direct, storev, n, k, v, ldv, tau, t, ldt )
call clazt( direct, storev, n, k, v, ldv, tau, t, ldt )
call zlazt( direct, storev, n, k, v, ldv, tau, t, ldt )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine forms the triangular factor T of a real/complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If `direct = 'F'`, $H = H(1) * H(2) * \dots * H(k)$, and T is upper triangular.

If `direct = 'B'`, $H = H(k) * \dots * H(2) * H(1)$, and T is lower triangular.

If `storev = 'C'`, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array `v`, and $H = I - V^* T^H V$

If `storev = 'R'`, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array `v`, and $H = I - V^* T^H V$

Currently, only `storev = 'R'` and `direct = 'B'` are supported.

Input Parameters

<code>direct</code>	CHARACTER*1. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: If <code>direct = 'F'</code> : $H = H(1) * H(2) * \dots * H(k)$ (forward, not supported) If <code>direct = 'B'</code> : $H = H(k) * \dots * H(2) * H(1)$ (backward)
<code>storev</code>	CHARACTER*1.

	Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): If <i>storev</i> = 'C': column-wise (not supported) If <i>storev</i> = 'R': row-wise
<i>n</i>	INTEGER. The order of the block reflector <i>H</i> . $n \geq 0$.
<i>k</i>	INTEGER. The order of the triangular factor <i>T</i> (equal to the number of elementary reflectors). $k \geq 1$.
<i>v</i>	REAL for slarzt DOUBLE PRECISION for dlarzt COMPLEX for clarzt COMPLEX*16 for zlarzt Array, DIMENSION (<i>ldv</i> , <i>k</i>) if <i>storev</i> = 'C' (<i>ldv</i> , <i>n</i>) if <i>storev</i> = 'R' The matrix <i>v</i> .
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> . If <i>storev</i> = 'C', $ldv \geq \max(1, n)$; if <i>storev</i> = 'R', $ldv \geq k$.
<i>tau</i>	REAL for slarzt DOUBLE PRECISION for dlarzt COMPLEX for clarzt COMPLEX*16 for zlarzt Array, DIMENSION (<i>k</i>). <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector <i>H</i> (<i>i</i>).
<i>ldt</i>	INTEGER. The leading dimension of the output array <i>t</i> . $ldt \geq k$.

Output Parameters

<i>t</i>	REAL for slarzt DOUBLE PRECISION for dlarzt COMPLEX for clarzt COMPLEX*16 for zlarzt Array, DIMENSION (<i>ldt</i> , <i>k</i>). The <i>k</i> -by- <i>k</i> triangular factor <i>T</i> of the block reflector. If <i>direct</i> = 'F', <i>T</i> is upper triangular; if <i>direct</i> = 'B', <i>T</i> is lower triangular. The rest of the array is not used.
----------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

v The matrix v . See *Application Notes* below.

Application Notes

The shape of the matrix v and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

`direct = 'F' and storev = 'C':` `direct = 'F' and storev = 'R':`

$$v = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot \\ & 1 & \cdot \\ & & 1 \end{bmatrix}$$

$$\begin{array}{c} \text{---}V\text{---} \\ / \qquad \backslash \end{array} \begin{bmatrix} v_1 & v_1 & v_1 & v_1 & v_1 & \cdot & \cdot & \cdot & \cdot & 1 \\ v_2 & v_2 & v_2 & v_2 & v_2 & \cdot & \cdot & \cdot & \cdot & 1 \\ v_3 & v_3 & v_3 & v_3 & v_3 & \cdot & \cdot & \cdot & 1 & \cdot \end{bmatrix}$$

`direct = 'B' and storev = 'C':` `direct = 'B' and storev = 'R':`

$$\mathbf{V} = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \end{bmatrix}$$

?las2

Computes singular values of a 2-by-2 triangular matrix.

Syntax

```
call slas2( f, g, h, ssmin, ssmax )
```

```
call dlas2( f, g, h, ssmin, ssmax )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?las2` computes the singular values of the 2-by-2 matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, *ssmin* is the smaller singular value and *ssmax* is the larger singular value.

Input Parameters

f, g, h REAL for *slas2*
 DOUBLE PRECISION for *dlas2*
 The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix,
 respectively.

Output Parameters

ssmin, ssmax REAL for *slas2*
 DOUBLE PRECISION for *dlas2*
 The smaller and the larger singular values, respectively.

Application Notes

Barring over/underflow, all output quantities are correct to within a few units in the last place (*ulps*), even in the absence of a guard digit in addition/subtraction. In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows, or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?lascl

Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .

Syntax

```
call slascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call dlascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call clascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call zlascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lascl` multiplies the m -by- n real/complex matrix A by the real scalar c_{to}/c_{from} . The operation is performed without over/underflow as long as the final result $c_{to} * A(i, j) / c_{from}$ does not over/underflow.

type specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Input Parameters

<i>type</i>	CHARACTER*1. This parameter specifies the storage type of the input matrix. = 'G': A is a full matrix. = 'L': A is a lower triangular matrix. = 'U': A is an upper triangular matrix. = 'H': A is an upper Hessenberg matrix. = 'B': A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the lower half stored = 'Q': A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the upper half stored. = 'Z': A is a band matrix with lower bandwidth kl and upper bandwidth ku .
<i>kl</i>	INTEGER. The lower bandwidth of A . Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.
<i>ku</i>	INTEGER. The upper bandwidth of A . Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.
<i>cfrom, cto</i>	REAL for <code>slascl/clascl</code> DOUBLE PRECISION for <code>dlascl/zlascl</code> The matrix A is multiplied by $cto/cfrom$. $A(i, j)$ is computed without over/underflow if the final result $cto * A(i, j) / cfrom$ can be represented without over/underflow. <i>cfrom</i> must be nonzero.
<i>m</i>	INTEGER. The number of rows of the matrix A . $m \geq 0$.

n INTEGER. The number of columns of the matrix *A*. $n \geq 0$.

a REAL for `slascl`
 DOUBLE PRECISION for `dlascl`
 COMPLEX for `clascl`
 COMPLEX*16 for `zlascl`
 Array, DIMENSION (*lda*, *n*). The matrix to be multiplied by *cto/cfrom*. See *type* for the storage type.

lda INTEGER. The leading dimension of the array *a*.
 $lda \geq \max(1, m)$.

Output Parameters

a The multiplied matrix *A*.

info INTEGER.
 If *info* = 0 - successful exit
 If *info* = -*i* < 0, the *i*-th argument had an illegal value.

?lasd0

Computes the singular values of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

```
call slasd0( n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info )
call dlasd0( n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

Using a divide and conquer approach, the routine `?lasd0` computes the singular value decomposition (SVD) of a real upper bidiagonal n -by- m matrix B with diagonal d and offdiagonal e , where $m = n + sqre$.

The algorithm computes orthogonal matrices U and VT such that $B = U^*S^*VT$. The singular values s are overwritten on d .

The related subroutine [?lasda](#) computes only the singular values, and optionally, the singular vectors in compact form.

Input Parameters

<i>n</i>	INTEGER. On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array <i>d</i> .
<i>sqre</i>	INTEGER. Specifies the column dimension of the bidiagonal matrix. If <i>sqre</i> = 0: the bidiagonal matrix has column dimension $m = n$. If <i>sqre</i> = 1: the bidiagonal matrix has column dimension $m = n+1$.
<i>d</i>	REAL for <code>slasd0</code> DOUBLE PRECISION for <code>dlsd0</code> Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for <code>slasd0</code> DOUBLE PRECISION for <code>dlsd0</code> Array, DIMENSION ($m-1$). Contains the subdiagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>ldu</i>	INTEGER. On entry, leading dimension of the output array <i>u</i> .
<i>ldvt</i>	INTEGER. On entry, leading dimension of the output array <i>vt</i> .
<i>smlsiz</i>	INTEGER. On entry, maximum size of the subproblems at the bottom of the computation tree.
<i>iwork</i>	INTEGER. Workspace array, dimension must be at least $(8n)$.
<i>work</i>	REAL for <code>slasd0</code> DOUBLE PRECISION for <code>dlsd0</code> Workspace array, dimension must be at least $(3m^2+2m)$.

Output Parameters

<i>d</i>	On exit <i>d</i> , If <i>info</i> = 0, contains singular values of the bidiagonal matrix.
----------	-------------------------------------------------------------------------------------------

u REAL for `slasd0`
 DOUBLE PRECISION for `dlsd0`
 Array, DIMENSION at least (*ldq*, *n*). On exit, *u* contains the
 left singular vectors.

vt REAL for `slasd0`
 DOUBLE PRECISION for `dlsd0`
 Array, DIMENSION at least (*ldvt*, *m*). On exit, *vt'* contains
 the right singular vectors.

info INTEGER.
 If *info* = 0: successful exit.
 If *info* = -*i* < 0, the *i*-th argument had an illegal value.
 If *info* = 1, an singular value did not converge.

?lasd1

*Computes the SVD of an upper bidiagonal matrix
 B of the specified size. Used by ?bdsdc.*

Syntax

```
call slasd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork,
            work, info )
```

```
call dlsd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork,
            work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the SVD of an upper bidiagonal n -by- m matrix B , where $n = nl + nr + 1$ and $m = n + sqre$.

The routine `?lasd1` is called from `?lasd0`.

A related subroutine `?lasd7` handles the case in which the singular values (and the singular vectors in factored form) are desired.

`?lasd1` computes the SVD as follows:

$$VT = U(in) * \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1' & a & Z2' & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$$= U(out) * (D(out) \ 0) * VT(out)$$

where $Z' = (Z1' \ a \ Z2' \ b) = u' * VT'$, and u is a vector of dimension m with $alpha$ and $beta$ in the $nl+1$ and $nl+2$ -th entries and zeros elsewhere; and the entry b is empty if $scre = 0$.

The left singular vectors of the original matrix are stored in u , and the transpose of the right singular vectors are stored in vt , and the singular values are in d . The algorithm consists of three stages:

- 1.** The first stage consists of deflating the size of the problem when there are multiple singular values or when there are zeros in the Z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine [?lasd2](#).
- 2.** The second stage consists of calculating the updated singular values. This is done by finding the square roots of the roots of the secular equation via the routine [?lasd4](#) (as called by [?lasd3](#)). This routine also calculates the singular vectors of the current problem.
- 3.** The final stage consists of computing the updated singular vectors directly using the updated singular values. The singular vectors for the current problem are multiplied with the singular vectors from the overall problem.

Input Parameters

nl	INTEGER. The row dimension of the upper block. $nl \geq 1$.
nr	INTEGER. The row dimension of the lower block. $nr \geq 1$.
$scre$	INTEGER. If $scre = 0$: the lower block is an nr -by- nr square matrix. If $scre = 1$: the lower block is an nr -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + scre$.
d	REAL for <code>slasd1</code>

	<p>DOUBLE PRECISION for dlasd1</p> <p>Array, DIMENSION ($nl+nr+1$). $n = nl+nr+1$. On entry $d(1:nl, 1:nl)$ contains the singular values of the upper block; and $d(nl+2:n)$ contains the singular values of the lower block.</p>
<i>alpha</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Contains the diagonal element associated with the added row.</p>
<i>beta</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Contains the off-diagonal element associated with the added row.</p>
<i>u</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Array, DIMENSION (ldu, n). On entry $u(1:nl, 1:nl)$ contains the left singular vectors of the upper block; $u(nl+2:n, nl+2:n)$ contains the left singular vectors of the lower block.</p>
<i>ldu</i>	<p>INTEGER. The leading dimension of the array <i>u</i>.</p> <p>$ldu \geq \max(1, n)$.</p>
<i>vt</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Array, DIMENSION ($ldvt, m$), where $m = n + sqre$. On entry $vt(1:nl+1, 1:nl+1)$ ' contains the right singular vectors of the upper block; $vt(nl+2:m, nl+2:m)$ ' contains the right singular vectors of the lower block.</p>
<i>ldvt</i>	<p>INTEGER. The leading dimension of the array <i>vt</i>.</p> <p>$ldvt \geq \max(1, M)$.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION ($4n$).</p>
<i>work</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Workspace array, DIMENSION ($3m_2 + 2m$).</p>

Output Parameters

<i>d</i>	On exit <i>d</i> (1: <i>n</i>) contains the singular values of the modified matrix.
<i>alpha</i>	On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D(I)}))$, $I = 1, n$.
<i>beta</i>	On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D(I)}))$, $I = 1, n$.
<i>u</i>	On exit <i>u</i> contains the left singular vectors of the bidiagonal matrix.
<i>vt</i>	On exit <i>vt'</i> contains the right singular vectors of the bidiagonal matrix.
<i>idxq</i>	INTEGER Array, DIMENSION (<i>n</i>). Contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, <i>d</i> (<i>idxq</i> (<i>i</i> = 1, <i>n</i>)) will be in ascending order.
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit. If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value. If <i>info</i> = 1, an singular value did not converge.

?lasd2

Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc.

Syntax

```
call slasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma,
u2, ldu2, vt2, ldvt2, idxp, idx, idxp, idxq, coltyp, info )

call dlasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma,
u2, ldu2, vt2, ldvt2, idxp, idx, idxp, idxq, coltyp, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?lasd2` merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

The routine `?lasd2` is called from `?lasd1`.

Input Parameters

<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sGRE</i>	INTEGER. If <i>sGRE</i> = 0): the lower block is an <i>nr</i> -by- <i>nr</i> square matrix If <i>sGRE</i> = 1): the lower block is an <i>nr</i> -by-(<i>nr</i> +1) rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sGRE \geq n$ columns.
<i>d</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlasd2</code> Array, DIMENSION (<i>n</i>). On entry <i>d</i> contains the singular values of the two submatrices to be combined.
<i>alpha</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlasd2</code> Contains the diagonal element associated with the added row.
<i>beta</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlasd2</code> Contains the off-diagonal element associated with the added row.
<i>u</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlasd2</code>

	<p>Array, DIMENSION (ldu, n). On entry u contains the left singular vectors of two submatrices in the two square blocks with corners at $(1,1)$, (nl, nl), and $(nl+2, nl+2)$, (n,n).</p>
ldu	<p>INTEGER. The leading dimension of the array u.</p> <p>$ldu \geq n$.</p>
$ldu2$	<p>INTEGER. The leading dimension of the output array $u2$.</p> <p>$ldu2 \geq n$.</p>
vt	<p>REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlasd2</code></p> <p>Array, DIMENSION ($ldvt, m$). On entry, vt' contains the right singular vectors of two submatrices in the two square blocks with corners at $(1,1)$, $(nl+1, nl+1)$, and $(nl+2, nl+2)$, (m, m).</p>
$ldvt$	<p>INTEGER. The leading dimension of the array vt. $ldvt \geq m$.</p>
$ldvt2$	<p>INTEGER. The leading dimension of the output array $vt2$.</p> <p>$ldvt2 \geq m$.</p>
$idxp$	<p>INTEGER.</p> <p>Workspace array, DIMENSION (n). This will contain the permutation used to place deflated values of d at the end of the array. On output $idxp(2:k)$ points to the nondeflated d-values and $idxp(k+1:n)$ points to the deflated singular values.</p>
idx	<p>INTEGER.</p> <p>Workspace array, DIMENSION (n). This will contain the permutation used to sort the contents of d into ascending order.</p>
$coltyp$	<p>INTEGER.</p> <p>Workspace array, DIMENSION (n). As workspace, this array contains a label that indicates which of the following types a column in the $u2$ matrix or a row in the $vt2$ matrix is:</p> <ul style="list-style-type: none"> 1 : non-zero in the upper half only 2 : non-zero in the lower half only 3 : dense 4 : deflated.

idxq INTEGER. Array, DIMENSION (n). This parameter contains the permutation that separately sorts the two sub-problems in D into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have n_l+1 added to their values.

Output Parameters

k INTEGER. Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. $1 \leq k \leq n$.

d On exit D contains the trailing $(n-k)$ updated singular values (those which were deflated) sorted into increasing order.

u On exit u contains the trailing $(n-k)$ updated left singular vectors (those which were deflated) in its last $n-k$ columns.

z REAL for slasd2
DOUBLE PRECISION for dlasd2
Array, DIMENSION (n). On exit, z contains the updating row vector in the secular equation.

dsigma REAL for slasd2
DOUBLE PRECISION for dlasd2
Array, DIMENSION (n). Contains a copy of the diagonal elements ($k-1$ singular values and one zero) in the secular equation.

u2 REAL for slasd2
DOUBLE PRECISION for dlasd2
Array, DIMENSION ($ldu2, n$). Contains a copy of the first $k-1$ left singular vectors which will be used by ?lasd3 in a matrix multiply (?gemm) to solve for the new left singular vectors. $u2$ is arranged into four blocks. The first block contains a column with 1 at n_l+1 and zero everywhere else; the second block contains non-zero entries only at and above n_l ; the third contains non-zero entries only below n_l+1 ; and the fourth is dense.

<code>vt</code>	On exit, <code>vt'</code> contains the trailing $(n-k)$ updated right singular vectors (those which were deflated) in its last $n-k$ columns. In case <code>sqre = 1</code> , the last row of <code>vt</code> spans the right null space.
<code>vt2</code>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlasd2</code> Array, DIMENSION $(ldvt2, n)$. <code>vt2'</code> contains a copy of the first k right singular vectors which will be used by <code>?lasd3</code> in a matrix multiply (<code>?gemm</code>) to solve for the new right singular vectors. <code>vt2</code> is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in <code>sigma</code> ; the second block contains non-zeros only at and before <code>nl + 1</code> ; the third block contains non-zeros only at and after <code>nl + 2</code> .
<code>idxc</code>	INTEGER. Array, DIMENSION (n) . This will contain the permutation used to arrange the columns of the deflated <code>u</code> matrix into three groups: the first group contains non-zero entries only at and above <code>nl</code> , the second contains non-zero entries only below <code>nl+2</code> , and the third is dense.
<code>coltyp</code>	On exit, it is an array of dimension 4, with <code>coltyp(i)</code> being the dimension of the i -th type columns.
<code>info</code>	INTEGER. If <code>info = 0</code>): successful exit If <code>info = -i < 0</code> , the i -th argument had an illegal value.

?lasd3

Finds all square roots of the roots of the secular equation, as defined by the values in `D` and `Z`, and then updates the singular vectors by matrix multiplication. Used by `?bdsdc`.

Syntax

```
call slasd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt,
vt2, ldvt2, idxc, ctot, z, info )

call dlasd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt,
vt2, ldvt2, idxc, ctot, z, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?lasd3` finds all the square roots of the roots of the secular equation, as defined by the values in D and Z .

It makes the appropriate calls to `?lasd4` and then updates the singular vectors by matrix multiplication.

The routine `?lasd3` is called from `?lasd1`.

Input Parameters

<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqre</i>	INTEGER. If <i>sqre</i> = 0): the lower block is an <i>nr</i> -by- <i>nr</i> square matrix. If <i>sqre</i> = 1): the lower block is an <i>nr</i> -by-(<i>nr</i> +1) rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqre \geq n$ columns.
<i>k</i>	INTEGER. The size of the secular equation, $1 \leq k \leq n$.
<i>q</i>	REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlasd3</code> Workspace array, DIMENSION at least (<i>ldq</i> , <i>k</i>).
<i>ldq</i>	INTEGER. The leading dimension of the array <i>q</i> . $ldq \geq k$.
<i>dsigma</i>	REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlasd3</code> Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i> . $ldu \geq n$.

<i>u2</i>	<p>REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlsd3</code> Array, DIMENSION (<i>ldu2</i>, <i>n</i>). The first <i>k</i> columns of this matrix contain the non-deflated left singular vectors for the split problem.</p>
<i>ldu2</i>	<p>INTEGER. The leading dimension of the array <i>u2</i>. $ldu2 \geq n$.</p>
<i>ldvt</i>	<p>INTEGER. The leading dimension of the array <i>vt</i>. $ldvt \geq n$.</p>
<i>vt2</i>	<p>REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlsd3</code> Array, DIMENSION (<i>ldvt2</i>, <i>n</i>). The first <i>k</i> columns of <i>vt2'</i> contain the non-deflated right singular vectors for the split problem.</p>
<i>ldvt2</i>	<p>INTEGER. The leading dimension of the array <i>vt2</i>. $ldvt2 \geq n$.</p>
<i>idxc</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>). The permutation used to arrange the columns of <i>u</i> (and rows of <i>vt</i>) into three groups: the first group contains non-zero entries only at and above (or before) <i>n1</i> +1; the second contains non-zero entries only at and below (or after) <i>n1</i>+2; and the third is dense. The first column of <i>u</i> and the row of <i>vt</i> are treated separately, however. The rows of the singular vectors found by <code>?lasd4</code> must be likewise permuted before the matrix multiplies can take place.</p>
<i>ctot</i>	<p>INTEGER. Array, DIMENSION (4). A count of the total number of the various types of columns in <i>u</i> (or rows in <i>vt</i>), as described in <i>idxc</i>. The fourth column type is any column which has been deflated.</p>
<i>z</i>	<p>REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlsd3</code> Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the components of the deflation-adjusted updating row vector.</p>

Output Parameters

<i>d</i>	<p>REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlsd3</code> Array, DIMENSION (<i>k</i>). On exit the square roots of the roots of the secular equation, in ascending order.</p>
<i>u</i>	<p>REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlsd3</code> Array, DIMENSION (<i>ldu</i>, <i>n</i>). The last <i>n</i> - <i>k</i> columns of this matrix contain the deflated left singular vectors.</p>
<i>vt</i>	<p>REAL for <code>slasd3</code> DOUBLE PRECISION for <code>dlsd3</code> Array, DIMENSION (<i>ldvt</i>, <i>m</i>). The last <i>m</i> - <i>k</i> columns of <i>vt</i>' contain the deflated right singular vectors.</p>
<i>vt2</i>	Destroyed on exit.
<i>z</i>	Destroyed on exit.
<i>info</i>	<p>INTEGER. If <i>info</i> = 0): successful exit. If <i>info</i> = -<i>i</i> < 0, the <i>i</i>-th argument had an illegal value. If <i>info</i> = 1, an singular value did not converge.</p>

Application Notes

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

?lasd4

Computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc.

Syntax

```
call slasd4( n, i, d, z, delta, rho, sigma, work, info )
```

```
call dlasd4( n, i, d, z, delta, rho, sigma, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array d , and that $0 \leq d(i) < d(j)$ for $i < j$ and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$$\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T,$$

where the Euclidean norm of z is equal to 1. The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

n	INTEGER. The length of all arrays.
i	INTEGER. The index of the eigenvalue to be computed. $1 \leq i \leq n$.
d	REAL for slasd4 DOUBLE PRECISION for dlasd4 Array, DIMENSION (n). The original eigenvalues. They must be in order, $0 \leq d(i) < d(j)$ for $i < j$.
z	REAL for slasd4 DOUBLE PRECISION for dlasd4

Array, DIMENSION (n).
 The components of the updating vector.

rho REAL for slasd4
 DOUBLE PRECISION for dlasd4
 The scalar in the symmetric updating formula.

work REAL for slasd4
 DOUBLE PRECISION for dlasd4
 Workspace array, DIMENSION (n).
 If $n \neq 1$, *work* contains ($d(j) + \text{sigma}_i$) in its j -th component.
 If $n = 1$, then *work*(1) = 1.

Output Parameters

delta REAL for slasd4
 DOUBLE PRECISION for dlasd4
 Array, DIMENSION (n).
 If $n \neq 1$, *delta* contains ($d(j) - \text{sigma}_i$) in its j -th component.
 If $n = 1$, then *delta* (1) = 1. The vector *delta* contains the information necessary to construct the (singular) eigenvectors.

sigma REAL for slasd4
 DOUBLE PRECISION for dlasd4
 The computed *sigma_i*, the i -th updated eigenvalue.

info INTEGER.
 = 0: successful exit
 > 0: If *info* = 1, the updating process failed.

?lasd5

Computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc.

Syntax

```
call slasd5( i, d, z, delta, rho, dsigma, work )
call dlasd5( i, d, z, delta, rho, dsigma, work )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix $\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T$

The diagonal entries in the array d must satisfy $0 \leq d(i) < d(j)$ for $i < j$, ρ must be greater than 0, and that the Euclidean norm of the vector z is equal to 1.

Input Parameters

i	<i>INTEGER</i> . The index of the eigenvalue to be computed. $i = 1$ or $i = 2$.
d	<i>REAL</i> for <code>slasd5</code> <i>DOUBLE PRECISION</i> for <code>dlasd5</code> Array, dimension (2). The original eigenvalues, $0 \leq d(1) < d(2)$.
z	<i>REAL</i> for <code>slasd5</code> <i>DOUBLE PRECISION</i> for <code>dlasd5</code> Array, dimension (2). The components of the updating vector.
ρ	<i>REAL</i> for <code>slasd5</code> <i>DOUBLE PRECISION</i> for <code>dlasd5</code> The scalar in the symmetric updating formula.
$work$	<i>REAL</i> for <code>slasd5</code> <i>DOUBLE PRECISION</i> for <code>dlasd5</code> .

Workspace array, dimension (2). Contains $(d(j) + \sigma_i)$ in its j -th component.

Output Parameters

<i>delta</i>	<p>REAL for slasd5 DOUBLE PRECISION for dlasd5. Array, dimension (2). Contains $(d(j) - \sigma_i)$ in its j-th component. The vector <i>delta</i> contains the information necessary to construct the eigenvectors.</p>
<i>dsigma</i>	<p>REAL for slasd5 DOUBLE PRECISION for dlasd5. The computed σ_i, the i-th updated eigenvalue.</p>

?lasd6

Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc.

Syntax

```
call slasd6( icompg, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr,
  givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork,
  info )

call dlasd6( icompg, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr,
  givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork,
  info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?lasd6 computes the SVD of an updated upper bidiagonal matrix B obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form. B is an

n -by- m matrix with $n = n_l + n_r + 1$ and $m = n + sqre$. A related subroutine, [?lasd1](#), handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired. [?lasd6](#) computes the *SVD* as follows:

$$B = U(in) * \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1' & a & Z2' & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$$= U(out) * (D(out) * VT(out))$$

where $Z' = (Z1' \ a \ Z2' \ b) = u' * VT'$, and u is a vector of dimension m with *alpha* and *beta* in the n_l+1 and n_l+2 -th entries and zeros elsewhere; and the entry b is empty if $sqre = 0$.

The singular values of B can be computed using $D1$, $D2$, the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in vf and vl , respectively, in [?lasd6](#). Hence U and VT are not explicitly referenced.

The singular values are stored in D . The algorithm consists of two stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine [?lasd7](#).
2. The second stage consists of calculating the updated singular values. This is done by finding the roots of the secular equation via the routine [?lasd4](#) (as called by [?lasd8](#)). This routine also updates vf and vl and computes the distances between the updated singular values and the old singular values. [?lasd6](#) is called from [?lasda](#).

Input Parameters

<i>icompg</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form: = 0: Compute singular values only = 1: Compute singular vectors in factored form as well.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block.

nr ≥ 1 .

sqre INTEGER .
 = 0: the lower block is an *nr*-by-*nr* square matrix.
 = 1: the lower block is an *nr*-by-(*nr*+1) rectangular matrix.
 The bidiagonal matrix has row dimension $n = n_l + n_r + 1$, and
 column dimension $m = n + sqre$.

d REAL for slasd6
 DOUBLE PRECISION for dlasd6
 Array, dimension (*n_l*+*n_r*+1). On entry *d*(1:*n_l*,1:*n_l*)
 contains the singular values of the upper block, and
d(*n_l*+2:*n*) contains the singular values of the lower block.

vf REAL for slasd6
 DOUBLE PRECISION for dlasd6
 Array, dimension (*m*).
 On entry, *vf*(1:*n_l*+1) contains the first components of all
 right singular vectors of the upper block; and *vf*(*n_l*+2:*m*)
 contains the first components of all right singular vectors
 of the lower block.

vl REAL for slasd6
 DOUBLE PRECISION for dlasd6
 Array, dimension (*m*).
 On entry, *vl*(1:*n_l*+1) contains the last components of all
 right singular vectors of the upper block; and *vl*(*n_l*+2:*m*)
 contains the last components of all right singular vectors of
 the lower block.

alpha REAL for slasd6
 DOUBLE PRECISION for dlasd6
 Contains the diagonal element associated with the added
 row.

beta REAL for slasd6
 DOUBLE PRECISION for dlasd6
 Contains the off-diagonal element associated with the added
 row.

ldgcol INTEGER. The leading dimension of the output array *givcol*,
 must be at least *n*.

ldgnum INTEGER.

The leading dimension of the output arrays *givnum* and *poles*, must be at least *n*.

work REAL for slasd6
DOUBLE PRECISION for dlasd6
Workspace array, dimension ($4m$).

iwork INTEGER.
Workspace array, dimension ($3n$).

Output Parameters

d On exit *d*(1:*n*) contains the singular values of the modified matrix.

vf On exit, *vf* contains the first components of all right singular vectors of the bidiagonal matrix.

vl On exit, *vl* contains the last components of all right singular vectors of the bidiagonal matrix.

alpha On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D}(\text{I}))), \text{I} = 1, n$.

beta On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D}(\text{I}))), \text{I} = 1, n$.

idxq INTEGER.
Array, dimension (*n*). This contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, *d*(*idxq*(*i* = 1, *n*)) will be in ascending order.

perm INTEGER.
Array, dimension (*n*). The permutations (from deflation and sorting) to be applied to each block. Not referenced if *icompq* = 0.

givptr INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if *icompq* = 0.

givcol INTEGER.

Array, dimension (*ldgcol*, 2). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if *icompg* = 0.

givnum REAL for *slasd6*
DOUBLE PRECISION for *dlsd6*
Array, dimension (*ldgnum*, 2). Each number indicates the *c* or *s* value to be used in the corresponding Givens rotation. Not referenced if *icompg* = 0.

poles REAL for *slasd6*
DOUBLE PRECISION for *dlsd6*
Array, dimension (*ldgnum*, 2). On exit, *poles*(1,*) is an array containing the new singular values obtained from solving the secular equation, and *poles*(2,*) is an array containing the poles in the secular equation. Not referenced if *icompg* = 0.

difl REAL for *slasd6*
DOUBLE PRECISION for *dlsd6*
Array, dimension (*n*). On exit, *difl*(*i*) is the distance between *i*-th updated (undeflated) singular value and the *i*-th (undeflated) old singular value.

difr REAL for *slasd6*
DOUBLE PRECISION for *dlsd6*
Array, dimension (*ldgnum*, 2) if *icompg* = 1 and dimension (*n*) if *icompg* = 0.
On exit, *difr*(*i*, 1) is the distance between *i*-th updated (undeflated) singular value and the *i*+1-th (undeflated) old singular value. If *icompg* = 1, *difr*(1: *k*, 2) is an array containing the normalizing factors for the right singular vector matrix.
See ?*lasd8* for details on *difl* and *difr*.

z REAL for *slasd6*
DOUBLE PRECISION for *dlsd6*
Array, dimension (*m*).
The first elements of this array contain the components of the deflation-adjusted updating row vector.

<i>k</i>	INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.
<i>c</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 <i>c</i> contains garbage if <i>sqre</i> = 0 and the <i>c</i> -value of a Givens rotation related to the right null space if <i>sqre</i> = 1.
<i>s</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 <i>s</i> contains garbage if <i>sqre</i> = 0 and the <i>s</i> -value of a Givens rotation related to the right null space if <i>sqre</i> = 1.
<i>info</i>	INTEGER. = 0: successful exit. < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. > 0: if <i>info</i> = 1, an singular value did not converge

?lasd7

Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc.

Syntax

```
call slasd7(  icompq, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta,
             dsigma, idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s,
             info )
```

```
call dlasd7(  icompq, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta,
             dsigma, idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s,
             info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lasd7` merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the z vector. For each such occurrence the order of the related secular equation problem is reduced by one. `?lasd7` is called from `?lasd6`.

Input Parameters

<i>icompg</i>	<p>INTEGER. Specifies whether singular vectors are to be computed in compact form, as follows:</p> <ul style="list-style-type: none"> = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.
<i>nl</i>	<p>INTEGER. The row dimension of the upper block.</p> <p>$nl \geq 1$.</p>
<i>nr</i>	<p>INTEGER. The row dimension of the lower block.</p> <p>$nr \geq 1$.</p>
<i>sqre</i>	<p>INTEGER.</p> <ul style="list-style-type: none"> = 0: the lower block is an nr-by-nr square matrix. = 1: the lower block is an nr-by-$(nr+1)$ rectangular matrix. <p>The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqre \geq n$ columns.</p>
<i>d</i>	<p>REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlasd7</code> Array, DIMENSION (n). On entry <i>d</i> contains the singular values of the two submatrices to be combined.</p>
<i>zw</i>	<p>REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlasd7</code> Array, DIMENSION (m). Workspace for z.</p>
<i>vf</i>	<p>REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlasd7</code> Array, DIMENSION (m). On entry, <code>vf(1:nl+1)</code> contains the first components of all right singular vectors of the upper block; and <code>vf(nl+2:m)</code> contains the first components of all right singular vectors of the lower block.</p>
<i>vw</i>	<p>REAL for <code>slasd7</code></p>

	DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). Workspace for <i>vf</i> .
<i>vl</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). On entry, <i>vl</i> (1: <i>n</i> l+1) contains the last components of all right singular vectors of the upper block; and <i>vl</i> (<i>n</i> l+2: <i>m</i>) contains the last components of all right singular vectors of the lower block.
<i>VLW</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). Workspace for <i>VL</i> .
<i>alpha</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7. Contains the diagonal element associated with the added row.
<i>beta</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Contains the off-diagonal element associated with the added row.
<i>idx</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to sort the contents of <i>d</i> into ascending order.
<i>idxp</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to place deflated values of <i>d</i> at the end of the array.
<i>idxq</i>	INTEGER. Array, DIMENSION (<i>n</i>). This contains the permutation which separately sorts the two sub-problems in <i>d</i> into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have <i>n</i> l+1 added to their values.

<i>ldgcol</i>	INTEGER. The leading dimension of the output array <i>givcol</i> , must be at least <i>n</i> .
<i>ldgnum</i>	INTEGER. The leading dimension of the output array <i>givnum</i> , must be at least <i>n</i> .

Output Parameters

<i>k</i>	INTEGER. Contains the dimension of the non-deflated matrix, this is the order of the related secular equation. $1 \leq k \leq n$.
<i>d</i>	On exit, <i>d</i> contains the trailing (<i>n-k</i>) updated singular values (those which were deflated) sorted into increasing order.
<i>z</i>	REAL for <i>slasd7</i> DOUBLE PRECISION for <i>dlasd7</i> . Array, DIMENSION (<i>m</i>). On exit, <i>z</i> contains the updating row vector in the secular equation.
<i>vf</i>	On exit, <i>vf</i> contains the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the last components of all right singular vectors of the bidiagonal matrix.
<i>dsigma</i>	REAL for <i>slasd7</i> DOUBLE PRECISION for <i>dlasd7</i> . Array, DIMENSION (<i>n</i>). Contains a copy of the diagonal elements (<i>k-1</i> singular values and one zero) in the secular equation.
<i>idxp</i>	On output, <i>idxp</i> (2: <i>k</i>) points to the nondeflated <i>d</i> -values and <i>idxp</i> (<i>k+1:n</i>) points to the deflated singular values.
<i>perm</i>	INTEGER. Array, DIMENSION (<i>n</i>). The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if <i>icompq</i> = 0.
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if <i>icompq</i> = 0.
<i>givcol</i>	INTEGER.

	<p>Array, DIMENSION (<i>ldgcol</i>, 2). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if <i>icompq</i> = 0.</p>
<i>givnum</i>	<p>REAL for <i>slasd7</i> DOUBLE PRECISION for <i>dlasd7</i>. Array, DIMENSION (<i>ldgnum</i>, 2). Each number indicates the <i>c</i> or <i>s</i> value to be used in the corresponding Givens rotation. Not referenced if <i>icompq</i> = 0.</p>
<i>c</i>	<p>REAL for <i>slasd7</i>. DOUBLE PRECISION for <i>dlasd7</i>. If <i>sqre</i> = 0, then <i>c</i> contains garbage, and if <i>sqre</i> = 1, then <i>c</i> contains <i>c</i>-value of a Givens rotation related to the right null space.</p>
<i>s</i>	<p>REAL for <i>slasd7</i>. DOUBLE PRECISION for <i>dlasd7</i>. If <i>sqre</i> = 0, then <i>s</i> contains garbage, and if <i>sqre</i> = 1, then <i>s</i> contains <i>s</i>-value of a Givens rotation related to the right null space.</p>
<i>info</i>	<p>INTEGER. = 0: successful exit. < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value.</p>

?lasd8

*Finds the square roots of the roots of the secular equation, and stores, for each element in *D*, the distance to its two nearest poles. Used by ?bdsdc.*

Syntax

```
call slasd8( icompq, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info
)
call dlasd8( icompq, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info
)
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?lasd8` finds the square roots of the roots of the secular equation, as defined by the values in *dsigma* and *z*. It makes the appropriate calls to `?lasd4`, and stores, for each element in *d*, the distance to its two nearest poles (elements in *dsigma*). It also updates the arrays *vf* and *vl*, the first and last components of all the right singular vectors of the original bidiagonal matrix. `?lasd8` is called from `?lasd6`.

Input Parameters

<i>icompg</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine: = 0: Compute singular values only. = 1: Compute singular vectors in factored form as well.
<i>k</i>	INTEGER. The number of terms in the rational function to be solved by <code>?lasd4</code> . $k \geq 1$.
<i>z</i>	REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code> . Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the components of the deflation-adjusted updating row vector.
<i>vf</i>	REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code> . Array, DIMENSION (<i>k</i>). On entry, <i>vf</i> contains information passed through <code>dbede8</code> .
<i>vl</i>	REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code> . Array, DIMENSION (<i>k</i>). On entry, <i>vl</i> contains information passed through <code>dbede8</code> .
<i>lddifr</i>	INTEGER. The leading dimension of the output array <i>difr</i> , must be at least <i>k</i> .
<i>dsigma</i>	REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code> . Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<i>work</i>	REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code> .

Workspace array, `DIMENSION` at least $(3k)$.

Output Parameters

<i>d</i>	<p>REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code>. Array, <code>DIMENSION (k)</code>. On output, <i>d</i> contains the updated singular values.</p>
<i>vf</i>	<p>On exit, <i>vf</i> contains the first <i>k</i> components of the first components of all right singular vectors of the bidiagonal matrix.</p>
<i>vl</i>	<p>On exit, <i>vl</i> contains the first <i>k</i> components of the last components of all right singular vectors of the bidiagonal matrix.</p>
<i>difl</i>	<p>REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code>. Array, <code>DIMENSION (k)</code>. On exit, $difl(i) = d(i) - dsigma(i)$.</p>
<i>difr</i>	<p>REAL for <code>slasd8</code> DOUBLE PRECISION for <code>dlasd8</code>. Array, <code>DIMENSION (lddifr, 2)</code> if <i>icompq</i> = 1 and <code>DIMENSION (k)</code> if <i>icompq</i> = 0. On exit, $difr(i,1) = d(i) - dsigma(i+1)$, $difr(k,1)$ is not defined and will not be referenced. If <i>icompq</i> = 1, $difr(1:k,2)$ is an array containing the normalizing factors for the right singular vector matrix.</p>
<i>info</i>	<p>INTEGER. = 0: successful exit. < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value. > 0: If <i>info</i> = 1, an singular value did not converge.</p>

?lasd9

Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc.

Syntax

```
call slasd9( icipq, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
call dlasd9( icipq, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?lasd9 finds the square roots of the roots of the secular equation, as defined by the values in *dsigma* and *z*. It makes the appropriate calls to ?lasd4, and stores, for each element in *d*, the distance to its two nearest poles (elements in *dsigma*). It also updates the arrays *vf* and *vl*, the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd9 is called from ?lasd7.

Input Parameters

<i>icipq</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine: If <i>icipq</i> = 0, compute singular values only; If <i>icipq</i> = 1, compute singular vector matrices in factored form also.
<i>k</i>	INTEGER. The number of terms in the rational function to be solved by slasd4. $k \geq 1$.
<i>dsigma</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9. Array, DIMENSION(<i>k</i>). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<i>z</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9.

	Array, DIMENSION (k). The first k elements of this array contain the components of the deflation-adjusted updating row vector.
<i>vf</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9. Array, DIMENSION(k). On entry, <i>vf</i> contains information passed through sbede8.
<i>vl</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9. Array, DIMENSION(k). On entry, <i>vl</i> contains information passed through sbede8.
<i>work</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9. Workspace array, DIMENSION at least $(3k)$.

Output Parameters

<i>d</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9. Array, DIMENSION(k). $d(i)$ contains the updated singular values.
<i>vf</i>	On exit, <i>vf</i> contains the first k components of the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the first k components of the last components of all right singular vectors of the bidiagonal matrix.
<i>difl</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9. Array, DIMENSION (k). On exit, $difl(i) = d(i) - dsigma(i)$.
<i>difr</i>	REAL for slasd9 DOUBLE PRECISION for dlasd9. Array, DIMENSION ($ldu, 2$) if <i>icompg</i> = 1 and DIMENSION (k) if <i>icompg</i> = 0.

On exit, $difr(i, 1) = d(i) - dsigma(i+1)$, $difr(k, 1)$ is not defined and will not be referenced.

If $icompg = 1$, $difr(1:k, 2)$ is an array containing the normalizing factors for the right singular vector matrix.

info

INTEGER.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

> 0: If $info = 1$, an singular value did not converge

?lasda

Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

call slasda(*icompg*, *smlsiz*, *n*, *sqr*, *d*, *e*, *u*, *ldu*, *vt*, *k*, *difl*, *difr*, *z*, *poles*, *givptr*, *givcol*, *ldgcol*, *perm*, *givnum*, *c*, *s*, *work*, *iwork*, *info*)

call dlasda(*icompg*, *smlsiz*, *n*, *sqr*, *d*, *e*, *u*, *ldu*, *vt*, *k*, *difl*, *difr*, *z*, *poles*, *givptr*, *givcol*, *ldgcol*, *perm*, *givnum*, *c*, *s*, *work*, *iwork*, *info*)

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

Using a divide and conquer approach, ?lasda computes the singular value decomposition (SVD) of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e , where $m = n + sqr$.

The algorithm computes the singular values in the $SVD B = U^* S^* V^T$. The orthogonal matrices U and V^T are optionally computed in compact form. A related subroutine ?lasd0 computes the singular values and the singular vectors in explicit form.

Input Parameters

icompg

INTEGER.

Specifies whether singular vectors are to be computed in compact form, as follows:

= 0: Compute singular values only.

	= 1: Compute singular vectors of upper bidiagonal matrix in compact form.
<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array <i>d</i> .
<i>sqre</i>	INTEGER. Specifies the column dimension of the bidiagonal matrix. If <i>sqre</i> = 0: the bidiagonal matrix has column dimension $m = n$ If <i>sqre</i> = 1: the bidiagonal matrix has column dimension $m = n + 1$.
<i>d</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION ($m - 1$). Contains the subdiagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>ldu</i>	INTEGER. The leading dimension of arrays <i>u</i> , <i>vt</i> , <i>difl</i> , <i>difr</i> , <i>poles</i> , <i>givnum</i> , and <i>z</i> . $ldu \geq n$.
<i>ldgcol</i>	INTEGER. The leading dimension of arrays <i>givcol</i> and <i>perm</i> . $ldgcol \geq n$.
<i>work</i>	REAL for slasda DOUBLE PRECISION for dlasda. Workspace array, DIMENSION $(6n + (smlsiz + 1)^2)$.
<i>iwork</i>	INTEGER. Workspace array, <i>Dimension</i> must be at least $(7n)$.

Output Parameters

<i>d</i>	On exit <i>d</i> , if <i>info</i> = 0, contains the singular values of the bidiagonal matrix.
<i>u</i>	REAL for slasda

DOUBLE PRECISION for dlasda.
 Array, DIMENSION (*ldu*, *smlsiz*) if *icompg* = 1.
 Not referenced if *icompg* = 0.
 If *icompg* = 1, on exit, *u* contains the left singular vector matrices of all subproblems at the bottom level.

vt REAL for slasda
 DOUBLE PRECISION for dlasda.
 Array, DIMENSION (*ldu*, *smlsiz*+1) if *icompg* = 1, and not referenced if *icompg* = 0. If *icompg* = 1, on exit, *vt* contains the right singular vector matrices of all subproblems at the bottom level.

k INTEGER.
 Array, DIMENSION (*n*) if *icompg* = 1 and DIMENSION (1) if *icompg* = 0.
 If *icompg* = 1, on exit, *k*(*i*) is the dimension of the *i*-th secular equation on the computation tree.

difl REAL for slasda
 DOUBLE PRECISION for dlasda.
 Array, DIMENSION (*ldu*, *nlvl*),
 where *nlvl* = floor(log₂(*n*/*smlsiz*)).

difr REAL for slasda
 DOUBLE PRECISION for dlasda.
 Array,
 DIMENSION (*ldu*, 2 *nlvl*) if *icompg* = 1 and DIMENSION (*n*) if *icompg* = 0.
 If *icompg* = 1, on exit, *difl*(1:*n*, *i*) and *difr*(1:*n*, 2 *i* - 1) record distances between singular values on the *i*-th level and singular values on the (*i* - 1)-th level, and *difr*(1:*n*, 2 *i*) contains the normalizing factors for the right singular vector matrix. See ?lasd8 for details.

z REAL for slasda
 DOUBLE PRECISION for dlasda.
 Array,
 DIMENSION (*ldu*, *nlvl*) if *icompg* = 1 and DIMENSION (*n*) if *icompg* = 0. The first *k* elements of *z*(1, *i*) contain the components of the deflation-adjusted updating row vector for subproblems on the *i*-th level.

<i>poles</i>	<p>REAL for slasda DOUBLE PRECISION for dlasda Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>poles</i>(1, 2<i>i</i> - 1) and <i>poles</i>(1, 2<i>i</i>) contain the new and old singular values involved in the secular equations on the <i>i</i>-th level.</p>
<i>givptr</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>givptr</i>(<i>i</i>) records the number of Givens rotations performed on the <i>i</i>-th problem on the computation tree.</p>
<i>givcol</i>	<p>INTEGER . Array, DIMENSION (<i>ldgcol</i>, 2*<i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, for each <i>i</i>, <i>givcol</i>(1, 2 <i>i</i> - 1) and <i>givcol</i>(1, 2 <i>i</i>) record the locations of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>perm</i>	<p>INTEGER . Array, DIMENSION (<i>ldgcol</i>, <i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>perm</i> (1, <i>i</i>) records permutations done on the <i>i</i>-th level of the computation tree.</p>
<i>givnum</i>	<p>REAL for slasda DOUBLE PRECISION for dlasda. Array DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, for each <i>i</i>, <i>givnum</i>(1, 2 <i>i</i> - 1) and <i>givnum</i>(1, 2 <i>i</i>) record the <i>C</i>- and <i>S</i>-values of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>c</i>	<p>REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>n</i>) if <i>icompg</i> = 1, and DIMENSION (1) if <i>icompg</i> = 0. If <i>icompg</i> = 1 and the <i>i</i>-th subproblem is not square, on exit, <i>c</i>(<i>i</i>) contains the <i>C</i>-value of a Givens rotation related to the right null space of the <i>i</i>-th subproblem.</p>
<i>s</i>	<p>REAL for slasda</p>

DOUBLE PRECISION for dlasda.
Array,
 DIMENSION (n) $icompg = 1$, and
 DIMENSION (1) if $icompg = 0$.
 If $icompg = 1$ and the i -th subproblem is not square, on
 exit, $s(i)$ contains the s -value of a Givens rotation related
 to the right null space of the i -th subproblem.

$info$ INTEGER.
 = 0: successful exit.
 < 0: if $info = -i$, the i -th argument had an illegal value
 > 0: If $info = 1$, an singular value did not converge

?lasdq

*Computes the SVD of a real bidiagonal matrix with
 diagonal d and off-diagonal e . Used by ?bdsdc.*

Syntax

```
call slasdq( uplo, sqre, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc,  
work, info )
```

```
call dlasdq( uplo, sqre, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc,  
work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?lasdq computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal d and off-diagonal e , accumulating the transformations if desired. If B is the input bidiagonal matrix, the algorithm computes orthogonal matrices Q and P such that $B = Q * S * P^T$. The singular values S are overwritten on d .

The input matrix U is changed to $U * Q$ if desired.

The input matrix VT is changed to $P^T * VT$ if desired.

The input matrix C is changed to $Q^T * C$ if desired.

Input Parameters

<i>uplo</i>	CHARACTER*1. On entry, <i>uplo</i> specifies whether the input bidiagonal matrix is upper or lower bidiagonal. If <i>uplo</i> = 'U' or 'u' , <i>B</i> is upper bidiagonal; If <i>uplo</i> = 'L' or 'l' , <i>B</i> is lower bidiagonal.
<i>sqre</i>	INTEGER. = 0: then the input matrix is <i>n</i> -by- <i>n</i> . = 1: then the input matrix is <i>n</i> -by-(<i>n</i> +1) if <i>uplu</i> = 'U' and (<i>n</i> +1)-by- <i>n</i> if <i>uplu</i> = 'L'. The bidiagonal matrix has $n = n_l + n_r + 1$ rows and $m = n + sqre \geq n$ columns.
<i>n</i>	INTEGER. On entry, <i>n</i> specifies the number of rows and columns in the matrix. <i>n</i> must be at least 0.
<i>ncvt</i>	INTEGER. On entry, <i>ncvt</i> specifies the number of columns of the matrix <i>VT</i> . <i>ncvt</i> must be at least 0.
<i>nru</i>	INTEGER. On entry, <i>nru</i> specifies the number of rows of the matrix <i>U</i> . <i>nru</i> must be at least 0.
<i>ncc</i>	INTEGER. On entry, <i>ncc</i> specifies the number of columns of the matrix <i>C</i> . <i>ncc</i> must be at least 0.
<i>d</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> . Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the diagonal entries of the bidiagonal matrix.
<i>e</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> . Array, DIMENSION is (<i>n</i> -1) if <i>sqre</i> = 0 and <i>n</i> if <i>sqre</i> = 1. On entry, the entries of <i>e</i> contain the off-diagonal entries of the bidiagonal matrix.
<i>vt</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> . Array, DIMENSION (<i>ldvt</i> , <i>ncvt</i>). On entry, contains a matrix which on exit has been premultiplied by P^T , dimension <i>n</i> -by- <i>ncvt</i> if <i>sqre</i> = 0 and (<i>n</i> +1)-by- <i>ncvt</i> if <i>sqre</i> = 1 (not referenced if <i>ncvt</i> =0).

<i>ldvt</i>	INTEGER. On entry, <i>ldvt</i> specifies the leading dimension of <i>vt</i> as declared in the calling (sub) program. <i>ldvt</i> must be at least 1. If <i>ncvt</i> is nonzero, <i>ldvt</i> must also be at least <i>n</i> .
<i>u</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlsdq</i> . Array, DIMENSION (<i>ldu</i> , <i>n</i>). On entry, contains a matrix which on exit has been postmultiplied by <i>Q</i> , dimension <i>nru</i> -by- <i>n</i> if <i>sqre</i> = 0 and <i>nru</i> -by- <i>(n+1)</i> if <i>sqre</i> = 1 (not referenced if <i>nru</i> =0).
<i>ldu</i>	INTEGER. On entry, <i>ldu</i> specifies the leading dimension of <i>u</i> as declared in the calling (sub) program. <i>ldu</i> must be at least $\max(1, \text{ } nru \text{ })$.
<i>c</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlsdq</i> . Array, DIMENSION (<i>ldc</i> , <i>ncc</i>). On entry, contains an <i>n</i> -by- <i>ncc</i> matrix which on exit has been premultiplied by <i>Q'</i> , dimension <i>n</i> -by- <i>ncc</i> if <i>sqre</i> = 0 and <i>(n+1)</i> -by- <i>ncc</i> if <i>sqre</i> = 1 (not referenced if <i>ncc</i> =0).
<i>ldc</i>	INTEGER. On entry, <i>ldc</i> specifies the leading dimension of <i>c</i> as declared in the calling (sub) program. <i>ldc</i> must be at least 1. If <i>ncc</i> is non-zero, <i>ldc</i> must also be at least <i>n</i> .
<i>work</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlsdq</i> . Array, DIMENSION (4 <i>n</i>). This is a workspace array. Only referenced if one of <i>ncvt</i> , <i>nru</i> , or <i>ncc</i> is nonzero, and if <i>n</i> is at least 2.

Output Parameters

<i>d</i>	On normal exit, <i>d</i> contains the singular values in ascending order.
<i>e</i>	On normal exit, <i>e</i> will contain 0. If the algorithm does not converge, <i>d</i> and <i>e</i> will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.
<i>vt</i>	On exit, the matrix has been premultiplied by <i>P'</i> .

<i>u</i>	On exit, the matrix has been postmultiplied by Q .
<i>c</i>	On exit, the matrix has been premultiplied by Q' .
<i>info</i>	INTEGER. On exit, a value of 0 indicates a successful exit. If <i>info</i> < 0, argument number - <i>info</i> is illegal. If <i>info</i> > 0, the algorithm did not converge, and <i>info</i> specifies how many superdiagonals did not converge.

?lasdt

Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc.

Syntax

```
call slasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
call dlasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine creates a tree of subproblems for bidiagonal divide and conquer.

Input Parameters

<i>n</i>	INTEGER. On entry, the number of diagonal elements of the bidiagonal matrix.
<i>msub</i>	INTEGER. On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

Output Parameters

<i>lvl</i>	INTEGER. On exit, the number of levels on the computation tree.
<i>nd</i>	INTEGER. On exit, the number of nodes on the tree.
<i>inode</i>	INTEGER. Array, DIMENSION (<i>n</i>). On exit, centers of subproblems.
<i>ndiml</i>	INTEGER .

ndimr Array, DIMENSION (*n*). On exit, row dimensions of left children.

ndimr INTEGER .

ndimr Array, DIMENSION (*n*). On exit, row dimensions of right children.

zlaset

Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.

Syntax

```
call slaset( uplo, m, n, alpha, beta, a, lda )
call dlaset( uplo, m, n, alpha, beta, a, lda )
call claset( uplo, m, n, alpha, beta, a, lda )
call zlaset( uplo, m, n, alpha, beta, a, lda )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine initializes an *m*-by-*n* matrix *A* to *beta* on the diagonal and *alpha* on the off-diagonals.

Input Parameters

uplo CHARACTER*1. Specifies the part of the matrix *A* to be set.
If *uplo* = 'U', upper triangular part is set; the strictly lower triangular part of *A* is not changed.
If *uplo* = 'L': lower triangular part is set; the strictly upper triangular part of *A* is not changed.
Otherwise: All of the matrix *A* is set.

m INTEGER. The number of rows of the matrix *A*. $m \geq 0$.

n INTEGER. The number of columns of the matrix *A*.
 $n \geq 0$.

alpha, beta REAL for slaset
DOUBLE PRECISION for dlaset

	COMPLEX for claset COMPLEX*16 for zlaset. The constants to which the off-diagonal and diagonal elements are to be set, respectively.
<i>a</i>	REAL for slaset DOUBLE PRECISION for dlaset COMPLEX for claset COMPLEX*16 for zlaset. Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.

Output Parameters

<i>a</i>	On exit, the leading <i>m</i> -by- <i>n</i> submatrix of <i>A</i> is set as follows: if <i>uplo</i> = 'U', $A(i, j) = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$, if <i>uplo</i> = 'L', $A(i, j) = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$, otherwise, $A(i, j) = \alpha, 1 \leq i \leq m, 1 \leq j \leq n, i \neq j$, and, for all <i>uplo</i> , $A(i, i) = \beta, 1 \leq i \leq \min(m, n)$.
----------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

?lasq1

*Computes the singular values of a real square
bidiagonal matrix. Used by ?bdsqr.*

Syntax

```
call slasq1( n, d, e, work, info )
call dlasq1( n, d, e, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lasql` computes the singular values of a real n -by- n bidiagonal matrix with diagonal d and off-diagonal e . The singular values are computed to high relative accuracy, in the absence of denormalization, underflow and overflow.

Input Parameters

n	INTEGER. The number of rows and columns in the matrix. $n \geq 0$.
d	REAL for <code>slasql</code> DOUBLE PRECISION for <code>dlasql</code> . Array, DIMENSION (n). On entry, d contains the diagonal elements of the bidiagonal matrix whose <i>SVD</i> is desired.
e	REAL for <code>slasql</code> DOUBLE PRECISION for <code>dlasql</code> . Array, DIMENSION (n). On entry, elements $e(1:n-1)$ contain the off-diagonal elements of the bidiagonal matrix whose <i>SVD</i> is desired.
$work$	REAL for <code>slasql</code> DOUBLE PRECISION for <code>dlasql</code> . Workspace array, DIMENSION ($4n$).

Output Parameters

d	On normal exit, d contains the singular values in decreasing order.
e	On exit, e is overwritten.
$info$	INTEGER. = 0: successful exit; < 0: if $info = -i$, the i -th argument had an illegal value; > 0: the algorithm failed: = 1, a split was marked by a positive value in e ; = 2, current block of z not diagonalized after $30n$ iterations (in inner while loop); = 3, termination criterion of outer while loop not met (program created more than n unreduced blocks).

?lasq2

Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the qd array z to high relative accuracy. Used by ?bdsqr and ?stegr.

Syntax

```
call slasq2( n, z, info )
```

```
call dlasq2( n, z, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?lasq2 computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the qd array z to high relative accuracy, in the absence of denormalization, underflow and overflow.

To see the relation of z to the tridiagonal matrix, let L be a unit lower bidiagonal matrix with subdiagonals $z(2,4,6,...)$ and let U be an upper bidiagonal matrix with 1's above and diagonal $z(1,3,5,...)$. The tridiagonal is LU or, if you prefer, the symmetric tridiagonal to which it is similar.

Input Parameters

n	INTEGER. The number of rows and columns in the matrix. $n \geq 0$.
z	REAL for slasq2 DOUBLE PRECISION for dlasq2. Array, DIMENSION (4 * n). On entry, z holds the qd array.

Output Parameters

<i>z</i>	On exit, entries 1 to <i>n</i> hold the eigenvalues in decreasing order, <i>z</i> (2 <i>n</i> +1) holds the trace, and <i>z</i> (2 <i>n</i> +2) holds the sum of the eigenvalues. If <i>n</i> > 2, then <i>z</i> (2 <i>n</i> +3) holds the iteration count, <i>z</i> (2 <i>n</i> +4) holds <i>ndivs</i> / <i>n</i> <i>in</i> ² , and <i>z</i> (2 <i>n</i> +5) holds the percentage of shifts that failed.
<i>info</i>	INTEGER. = 0: successful exit; < 0: if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> , if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); > 0: the algorithm failed: = 1, a split was marked by a positive value in <i>e</i> ; = 2, current block of <i>z</i> not diagonalized after 30* <i>n</i> iterations (in inner while loop); = 3, termination criterion of outer while loop not met (program created more than <i>n</i> unreduced blocks).

Application Notes

The routine ?lasq2 defines a logical variable, *ieee*, which is `.TRUE.` on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs, and `.FALSE.` otherwise. This variable is passed to ?lazq3.

?lasq3

Checks for deflation, computes a shift and calls dqds. Used by ?bdsqr.

Syntax

```
call slasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee
)
call dlasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee
)
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lasq3` checks for deflation, computes a shift, and calls `dqds`. In case of failure, it changes shifts, and tries again until output is positive.

WARNING. The `?lasq3` routine is not thread-safe. It is deprecated and retained for the backward compatibility only. Use the thread-safe `?lazq3` routine instead.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the <i>qd</i> array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>desig</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Lower order part of <i>sigma</i> .
<i>qmax</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Maximum value of <i>q</i> .
<i>ieee</i>	LOGICAL. Flag for ieee or non-ieee arithmetic (passed to <code>?lasq5</code>).

Output Parameters

<i>dmin</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Minimum value of <i>d</i> .
<i>sigma</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Sum of shifts used in current segment.
<i>desig</i>	Lower order part of <i>sigma</i> .

<i>nfail</i>	INTEGER. Number of times shift was too big.
<i>iter</i>	INTEGER. Number of iterations.
<i>ndiv</i>	INTEGER. Number of divisions.

?lasq4

Computes an approximation to the smallest eigenvalue using values of d from the previous transform. Used by ?bdsqr.

Syntax

```
call slasq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype
)
call dlasq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype
)
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes an approximation *tau* to the smallest eigenvalue using values of *d* from the previous transform.

WARNING. The ?lasq4 routine is not thread-safe. It is deprecated and retained for the backward compatibility only. Use the thread-safe ?lazq4 routine instead.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the <i>qd</i> array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>n0in</i>	INTEGER. The value of <i>n0</i> at start of eigtest.

<i>dmin</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>).
<i>dmin2</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1).
<i>dn</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains <i>d</i> (<i>n</i>).
<i>dn1</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains <i>d</i> (<i>n</i> -1).
<i>dn2</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains <i>d</i> (<i>n</i> -2).

Output Parameters

<i>tau</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Shift.
<i>ttype</i>	INTEGER. Shift type.

?lasq5

*Computes one dqds transform in ping-pong form.
Used by ?bdsqr and ?stegr.*

Syntax

```
call slasq5( i0, n0, z, pp, tau, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee )
call dlasq5( i0, n0, z, pp, tau, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes one dqds transform in ping-pong form: one version for ieee machines, another for non-ieee machines.

Input Parameters

i0 INTEGER. First index.
n0 INTEGER. Last index.
z REAL for slasq5
 DOUBLE PRECISION for dlasq5.
 Array, DIMENSION (4*n*). *z* holds the qd array. *emin* is stored in *z*(4**n0*) to avoid an extra argument.
pp INTEGER. *pp*=0 for ping, *pp*=1 for pong.
tau REAL for slasq5
 DOUBLE PRECISION for dlasq5.
 This is the shift.
ieee LOGICAL. Flag for IEEE or non-IEEE arithmetic.

Output Parameters

dmin REAL for slasq5
 DOUBLE PRECISION for dlasq5.
 Minimum value of *d*.
dmin1 REAL for slasq5
 DOUBLE PRECISION for dlasq5.
 Minimum value of *d*, excluding *d*(*n0*).
dmin2 REAL for slasq5
 DOUBLE PRECISION for dlasq5.
 Minimum value of *d*, excluding *d*(*n0*) and *d*(*n0*-1).
dn REAL for slasq5
 DOUBLE PRECISION for dlasq5. Contains *d*(*n0*), the last value of *d*.
dnm1 REAL for slasq5
 DOUBLE PRECISION for dlasq5. Contains *d*(*n0*-1).
dnm2 REAL for slasq5
 DOUBLE PRECISION for dlasq5. Contains *d*(*n0*-2).

?lasq6

*Computes one dqd transform in ping-pong form.
Used by ?bdsqr and ?stegr.*

Syntax

```
call slasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
call dlasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lasq6 computes one dqd (shift equal to zero) transform in ping-pong form, with protection against underflow and overflow.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for slasq6 DOUBLE PRECISION for dlasq6. Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the qd array. <i>emin</i> is stored in <i>z</i> (4* <i>n0</i>) to avoid an extra argument.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.

Output Parameters

<i>dmin</i>	REAL for slasq6 DOUBLE PRECISION for dlasq6. Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for slasq6 DOUBLE PRECISION for dlasq6. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>).
<i>dmin2</i>	REAL for slasq6 DOUBLE PRECISION for dlasq6. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1).
<i>dn</i>	REAL for slasq6

	DOUBLE PRECISION for dlasq6. Contains $d(n0)$, the last value of d .
$dnm1$	REAL for slasq6 DOUBLE PRECISION for dlasq6. Contains $d(n0-1)$.
$dnm2$	REAL for slasq6 DOUBLE PRECISION for dlasq6. Contains $d(n0-2)$.

?lasr

Applies a sequence of plane rotations to a general rectangular matrix.

Syntax

```
call slasr( side, pivot, direct, m, n, c, s, a, lda )
call dlasr( side, pivot, direct, m, n, c, s, a, lda )
call clasr( side, pivot, direct, m, n, c, s, a, lda )
call zlasr( side, pivot, direct, m, n, c, s, a, lda )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine applies a sequence of plane rotations to a real/complex matrix A , from the left or the right.

$A := P^*A$, when $side = 'L'$ (Left-hand side)

$A := A^*P$, when $side = 'R'$ (Right-hand side)

where P is an orthogonal matrix consisting of a sequence of plane rotations with $z = m$ when $side = 'L'$ and $z = n$ when $side = 'R'$.

When $direct = 'F'$ (Forward sequence), then

$P = P(z-1) * \dots * P(2) * P(1)$,

and when $direct = 'B'$ (Backward sequence), then

$P = P(1) * P(2) * \dots * P(z-1)$,

where $P(k)$ is a plane rotation matrix defined by the 2-by-2 plane rotation:

$$R(k) = \begin{bmatrix} c(k) & s(k) \\ -s(k) & c(k) \end{bmatrix}$$

When $pivot = 'V'$ (Variable pivot), the rotation is performed for the plane $(k, k + 1)$, that is, $P(k)$ has the form

$$P(k) = \begin{bmatrix} 1 & & & & & \\ & \dots & & & & \\ & & 1 & & & \\ & & & c(k) & s(k) & \\ & & & -s(k) & c(k) & \\ & & & & & 1 \\ & & & & & \dots \\ & & & & & & 1 \end{bmatrix}$$

where $R(k)$ appears as a rank-2 modification to the identity matrix in rows and columns k and $k+1$.

When $pivot = 'T'$ (Top pivot), the rotation is performed for the plane $(1, k+1)$, so $P(k)$ has the form

$$P(k) = \begin{bmatrix} c(k) & & & s(k) & & \\ & 1 & & & & \\ & & \dots & & & \\ & & & 1 & & \\ -s(k) & & & & c(k) & \\ & & & & & 1 \\ & & & & & \dots \\ & & & & & & 1 \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and $k+1$.

Similarly, when $pivot = 'B'$ (Bottom pivot), the rotation is performed for the plane (k, z) , giving $P(k)$ the form

$$P(k) = \begin{bmatrix} 1 & & & & & \\ & \dots & & & & \\ & & 1 & & & \\ & & & c(k) & & s(k) \\ & & & & 1 & \\ & & & & & \dots \\ & & & & & & 1 \\ & & & -s(k) & & & c(k) \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and z . The rotations are performed without ever forming $P(k)$ explicitly.

Input Parameters

side CHARACTER*1. Specifies whether the plane rotation matrix P is applied to A on the left or the right.

	<p>= 'L': left, compute $A := P^*A$</p> <p>= 'R': right, compute $A := A^*P$</p>
<i>direct</i>	<p>CHARACTER*1. Specifies whether P is a forward or backward sequence of plane rotations.</p> <p>= 'F': forward, $P = P(z-1) * \dots * P(2) * P(1)$</p> <p>= 'B': backward, $P = P(1) * P(2) * \dots * P(z-1)$</p>
<i>pivot</i>	<p>CHARACTER*1. Specifies the plane for which $P(k)$ is a plane rotation matrix.</p> <p>= 'V': Variable pivot, the plane $(k, k+1)$</p> <p>= 'T': Top pivot, the plane $(1, k+1)$</p> <p>= 'B': Bottom pivot, the plane (k, z)</p>
<i>m</i>	<p>INTEGER. The number of rows of the matrix A.</p> <p>If $m \leq 1$, an immediate return is effected.</p>
<i>n</i>	<p>INTEGER. The number of columns of the matrix A.</p> <p>If $n \leq 1$, an immediate return is effected.</p>
<i>c, s</i>	<p>REAL for slasr/clasr</p> <p>DOUBLE PRECISION for dlasr/zlasr.</p> <p>Arrays, DIMENSION</p> <p>$(m-1)$ if $side = 'L'$,</p> <p>$(n-1)$ if $side = 'R'$.</p> <p>$c(k)$ and $s(k)$ contain the cosine and sine of the plane rotations respectively that define the 2-by-2 plane rotation part ($R(k)$) of the $P(k)$ matrix as described above in <i>Description</i>.</p>
<i>a</i>	<p>REAL for slasr</p> <p>DOUBLE PRECISION for dlasr</p> <p>COMPLEX for clasr</p> <p>COMPLEX*16 for zlasr.</p> <p>Array, DIMENSION (lda, n).</p> <p>The m-by-n matrix A.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array a.</p> <p>$lda \geq \max(1, m)$.</p>

Output Parameters

a On exit, *A* is overwritten by P^*A if *side* = 'R', or by A^*P if *side* = 'L'.

?lasrt

Sorts numbers in increasing or decreasing order.

Syntax

```
call slasrt( id, n, d, info )
```

```
call dlasrt( id, n, d, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lasrt sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of `stack` limits *n* to about 2^{32} .

Input Parameters

id CHARACTER*1.
= 'I': sort *d* in increasing order;
= 'D': sort *d* in decreasing order.

n INTEGER. The length of the array *d*.

d REAL for slasrt
DOUBLE PRECISION for dlasrt.
On entry, the array to be sorted.

Output Parameters

d On exit, *d* has been sorted into increasing order
($d(1) \leq \dots \leq d(n)$) or into decreasing order
($d(1) \geq \dots \geq d(n)$), depending on *id*.

info INTEGER.
= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call slassq( n, x, incx, scale, sumsq )
call dlassq( n, x, incx, scale, sumsq )
call classq( n, x, incx, scale, sumsq )
call zlassq( n, x, incx, scale, sumsq )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The real routines `slassq/dlassq` return the values *scl* and *smSQ* such that

$$scl^2 * smSQ = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = x(1 + (i - 1) * incx)$.

The value of *sumsq* is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, abs(x(i))).$$

Values *scale* and *sumsq* must be supplied in *scale* and *sumsq*, and *scl* and *smSQ* are overwritten on *scale* and *sumsq*, respectively.

The complex routines `classq/zlassq` return the values *scl* and *ssq* such that

$$scl^2 * ssq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = abs(x(1 + (i - 1) * incx))$.

The value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy 1.0

$$\leq ssq \leq sumsq + 2n$$

scale is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, abs(real(x(i))), abs(aimag(x(i)))).$$

Values *scale* and *sumsq* must be supplied in *scale* and *sumsq*, and *scl* and *ssq* are overwritten on *scale* and *sumsq*, respectively.

All routines `?lassq` make only one pass through the vector *x*.

Input Parameters

<i>n</i>	INTEGER. The number of elements to be used from the vector <i>x</i> .
<i>x</i>	REAL for <code>slassq</code> DOUBLE PRECISION for <code>dlassq</code> COMPLEX for <code>classq</code> COMPLEX*16 for <code>zlassq</code> . The vector for which a scaled sum of squares is computed: $x(i) = x(1+(i-1)*incx), 1 \leq i \leq n$.
<i>incx</i>	INTEGER. The increment between successive values of the vector <i>x</i> . <i>incx</i> > 0.
<i>scale</i>	REAL for <code>slassq/classq</code> DOUBLE PRECISION for <code>dlassq/zlassq</code> . On entry, the value <i>scale</i> in the equation above.
<i>sumsq</i>	REAL for <code>slassq/classq</code> DOUBLE PRECISION for <code>dlassq/zlassq</code> . On entry, the value <i>sumsq</i> in the equation above.

Output Parameters

<i>scale</i>	On exit, <i>scale</i> is overwritten with <i>scl</i> , the scaling factor for the sum of squares.
<i>sumsq</i>	For real flavors: On exit, <i>sumsq</i> is overwritten with the value <i>smsq</i> in the equation above. For complex flavors: On exit, <i>sumsq</i> is overwritten with the value <i>ssq</i> in the equation above.

?lasv2

Computes the singular value decomposition of a 2-by-2 triangular matrix.

Syntax

```
call slasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
call dlasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lasv2 computes the singular value decomposition of a 2-by-2 triangular matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, `abs(ssmax)` is the larger singular value, `abs(ssmin)` is the smaller singular value, and `(csl,snl)` and `(csr,snr)` are the left and right singular vectors for `abs(ssmax)`, giving the decomposition

$$\begin{bmatrix} csl & snl \\ -snl & csl \end{bmatrix} \begin{bmatrix} f & g \\ 0 & h \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix} = \begin{bmatrix} ssmax & 0 \\ 0 & ssmin \end{bmatrix}$$

Input Parameters

f, g, h REAL for slasv2
 DOUBLE PRECISION for dlasv2.
 The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix, respectively.

Output Parameters

ssmin, ssmax REAL for slasv2

DOUBLE PRECISION for dlasv2.
 $\text{abs}(ssmin)$ and $\text{abs}(ssmax)$ is the smaller and the larger
singular value, respectively.

snl, cs1 REAL for slasv2
DOUBLE PRECISION for dlasv2.
The vector (*cs1, snl*) is a unit left singular vector for the
singular value $\text{abs}(ssmax)$.

snr, csr REAL for slasv2
DOUBLE PRECISION for dlasv2.
The vector (*csr, snr*) is a unit right singular vector for the
singular value $\text{abs}(ssmax)$.

Application Notes

Any input parameter may be aliased with any output parameter.

Barring over/underflow and assuming a guard digit in subtraction, all output quantities are correct to within a few units in the last place (ulps).

In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call slaswp( n, a, lda, k1, k2, ipiv, incx )
call dlaswp( n, a, lda, k1, k2, ipiv, incx )
call claswp( n, a, lda, k1, k2, ipiv, incx )
call zlaswp( n, a, lda, k1, k2, ipiv, incx )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine performs a series of row interchanges on the matrix *A*. One row interchange is initiated for each of rows *k1* through *k2* of *A*.

Input Parameters

<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> .
<i>a</i>	REAL for <code>slaswp</code> DOUBLE PRECISION for <code>dlaswp</code> COMPLEX for <code>claswp</code> COMPLEX*16 for <code>zlaswp</code> . Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the matrix of column dimension <i>n</i> to which the row interchanges will be applied.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> .
<i>k1</i>	INTEGER. The first element of <i>ipiv</i> for which a row interchange will be done.
<i>k2</i>	INTEGER. The last element of <i>ipiv</i> for which a row interchange will be done.
<i>ipiv</i>	INTEGER. Array, DIMENSION (<i>k2</i> * <i>incx</i>). The vector of pivot indices. Only the elements in positions <i>k1</i> through <i>k2</i> of <i>ipiv</i> are accessed. <i>ipiv</i> (<i>k</i>) = <i>l</i> implies rows <i>k</i> and <i>l</i> are to be interchanged.
<i>incx</i>	INTEGER. The increment between successive values of <i>ipiv</i> . If <i>ipiv</i> is negative, the pivots are applied in reverse order.

Output Parameters

<i>a</i>	On exit, the permuted matrix.
----------	-------------------------------

slasy2

Solves the Sylvester matrix equation where the matrices are of order 1 or 2.

Syntax

```
call slasy2( ltranl, ltranr, isgn, n1, n2, tl, ldtl, tr, ldtr, b, ldb, scale,
x, ldx, xnorm, info )
```

```
call dlasy2( ltranl, ltranr, isgn, n1, n2, tl, ldtl, tr, ldtr, b, ldb, scale,
x, ldx, xnorm, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine solves for the $n1$ -by- $n2$ matrix X , $1 \leq n1, n2 \leq 2$, in

$$\text{op}(TL) * X + \text{isgn} * X * \text{op}(TR) = \text{scale} * B,$$

where

TL is $n1$ -by- $n1$,

TR is $n2$ -by- $n2$,

B is $n1$ -by- $n2$,

and $\text{isgn} = 1$ or -1 . $\text{op}(T) = T$ or T^T , where T^T denotes the transpose of T .

Input Parameters

<i>ltranl</i>	LOGICAL. On entry, <i>ltranl</i> specifies the $\text{op}(TL)$: = <code>.FALSE.</code> , $\text{op}(TL) = TL$, = <code>.TRUE.</code> , $\text{op}(TL) = (TL)^T$.
<i>ltranr</i>	LOGICAL. On entry, <i>ltranr</i> specifies the $\text{op}(TR)$: = <code>.FALSE.</code> , $\text{op}(TR) = TR$, = <code>.TRUE.</code> , $\text{op}(TR) = (TR)^T$.
<i>isgn</i>	INTEGER. On entry, <i>isgn</i> specifies the sign of the equation as described before. <i>isgn</i> may only be 1 or -1.

<i>n1</i>	INTEGER. On entry, <i>n1</i> specifies the order of matrix <i>TL</i> . <i>n1</i> may only be 0, 1 or 2.
<i>n2</i>	INTEGER. On entry, <i>n2</i> specifies the order of matrix <i>TR</i> . <i>n2</i> may only be 0, 1 or 2.
<i>t1</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. Array, DIMENSION (<i>ldt1</i> ,2). On entry, <i>t1</i> contains an <i>n1</i> -by- <i>n1</i> matrix <i>TL</i> .
<i>ldt1</i>	INTEGER. The leading dimension of the matrix <i>TL</i> . $ldt1 \geq \max(1, n1)$.
<i>tr</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. Array, DIMENSION (<i>ldtr</i> ,2). On entry, <i>tr</i> contains an <i>n2</i> -by- <i>n2</i> matrix <i>TR</i> .
<i>ldtr</i>	INTEGER. The leading dimension of the matrix <i>TR</i> . $ldtr \geq \max(1, n2)$.
<i>b</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. Array, DIMENSION (<i>ldb</i> ,2). On entry, the <i>n1</i> -by- <i>n2</i> matrix <i>B</i> contains the right-hand side of the equation.
<i>ldb</i>	INTEGER. The leading dimension of the matrix <i>B</i> . $ldb \geq \max(1, n1)$.
<i>ldx</i>	INTEGER. The leading dimension of the output matrix <i>X</i> . $ldx \geq \max(1, n1)$.

Output Parameters

<i>scale</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. On exit, <i>scale</i> contains the scale factor. <i>scale</i> is chosen less than or equal to 1 to prevent the solution overflowing.
<i>x</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2.

Array, DIMENSION ($ldx, 2$). On exit, x contains the $n1$ -by- $n2$ solution.

$xnorm$ REAL for `slasy2`
DOUBLE PRECISION for `dlasy2`.
On exit, $xnorm$ is the infinity-norm of the solution.

$info$ INTEGER. On exit, $info$ is set to 0: successful exit. 1: TL and TR have too close eigenvalues, so TL or TR is perturbed to get a nonsingular equation.

NOTE. For higher speed, this routine does not check the inputs for errors.

?lasyf

Computes a partial factorization of a real/complex symmetric matrix, using the diagonal pivoting method.

Syntax

```
call slasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call dlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call clasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lasyf` computes a partial factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{12}' \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}' & U_{12}' \end{bmatrix} \text{ if } uplo = 'U', \text{ or}$$

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}' & L_{21}' \\ 0 & I \end{bmatrix} \text{ if } uplo = 'L'$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

This is an auxiliary routine called by `?sytrf`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

$uplo$	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular
n	INTEGER. The order of the matrix A . $n \geq 0$.
nb	INTEGER. The maximum number of columns of the matrix A that should be factored. nb should be at least 2 to allow for 2-by-2 pivot blocks.
a	REAL for slasyf DOUBLE PRECISION for dlasyf COMPLEX for clasyf COMPLEX*16 for zlasyf. Array, DIMENSION (lda, n). If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.
w	REAL for slasyf DOUBLE PRECISION for dlasyf

COMPLEX for `clasyf`
 COMPLEX*16 for `zlasyf`.
 Workspace array, DIMENSION (ldw, nb).

ldw INTEGER. The leading dimension of the array w . $ldw \geq \max(1, n)$.

Output Parameters

kb INTEGER. The number of columns of A that were actually factored kb is either $nb-1$ or nb , or n if $n \leq nb$.

a On exit, a contains details of the partial factorization.

$ipiv$ INTEGER. Array, DIMENSION (n). Details of the interchanges and the block structure of D .

If $uplo = 'U'$, only the last kb elements of $ipiv$ are set;
 if $uplo = 'L'$, only the first kb elements are set.

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

$info$ INTEGER.
 = 0: successful exit
 > 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?lahef

Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.

Syntax

```
call clahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lahef` computes a partial factorization of a complex Hermitian matrix A , using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{12}' \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}' & U_{12}' \end{bmatrix} \text{ if } uplo = 'U', \text{ or}$$

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{12}' & L_{21}' \\ 0 & I \end{bmatrix} \text{ if } uplo = 'L'$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

Note that U' denotes the conjugate transpose of U .

This is an auxiliary routine called by `?hetrf`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

$uplo$ CHARACTER*1.

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

= 'U': upper triangular

= 'L': lower triangular

n	INTEGER. The order of the matrix A . $n \geq 0$.
nb	INTEGER. The maximum number of columns of the matrix A that should be factored. nb should be at least 2 to allow for 2-by-2 pivot blocks.
a	COMPLEX for <code>clahef</code> COMPLEX*16 for <code>zlahef</code> . Array, DIMENSION (lda , n). On entry, the Hermitian matrix A . If $uplo = 'U'$, the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.
w	COMPLEX for <code>clahef</code> COMPLEX*16 for <code>zlahef</code> . Workspace array, DIMENSION (ldw , nb).
ldw	INTEGER. The leading dimension of the array w . $ldw \geq \max(1, nb)$.

Output Parameters

kb	INTEGER. The number of columns of A that were actually factored kb is either $nb-1$ or nb , or n if $n \leq nb$.
a	On exit, A contains details of the partial factorization.
$ipiv$	INTEGER. Array, DIMENSION (n). Details of the interchanges and the block structure of D . If $uplo = 'U'$, only the last kb elements of $ipiv$ are set;

if $uplo = 'L'$, only the first kb elements are set.
 If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ are interchanged and $D(k, k)$ is a 1-by-1 diagonal block.
 If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ are interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.
 If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ are interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.
 = 0: successful exit
 > 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?latbs

Solves a triangular banded system of equations.

Syntax

```
call slatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
```

```
call dlatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
```

```
call clatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
```

```
call zlatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine solves one of the triangular systems

$A*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine `?tbsv` is called. If the matrix A is singular ($A(j, j)=0$ for some j), then s is set to 0 and a non-trivial solution to $A^*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': upper triangular = 'L': lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A^*x = s*b$ (no transpose) = 'T': solve $A^T*x = s*b$ (transpose) = 'C': solve $A^H*x = s*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular = 'N': non-unit triangular = 'U': unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> is set. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms is computed and stored in <i>cnorm</i> .
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>kd</i>	INTEGER. The number of subdiagonals or superdiagonals in the triangular matrix A . $kb \geq 0$.
<i>ab</i>	REAL for <i>slatbs</i> DOUBLE PRECISION for <i>dlatbs</i> COMPLEX for <i>clatbs</i> COMPLEX*16 for <i>zlatbs</i> . Array, DIMENSION (<i>ldab</i> , <i>n</i>).

The upper or lower triangular band matrix A , stored in the first $kb+1$ rows of the array. The j -th column of A is stored in the j -th column of the array ab as follows:

if $uplo = 'U'$, $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$;

if $uplo = 'L'$, $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

ldab

INTEGER. The leading dimension of the array ab . $ldab \geq kb+1$.

x

REAL for slatbs

DOUBLE PRECISION for dlatbs

COMPLEX for clatbs

COMPLEX*16 for zlatbs.

Array, DIMENSION (n).

On entry, the right hand side b of the triangular system.

cnorm

REAL for slatbs/clatbs

DOUBLE PRECISION for dlatbs/zlatbs.

Array, DIMENSION (n).

If $NORMIN = 'Y'$, $cnorm$ is an input argument and $cnorm(j)$ contains the norm of the off-diagonal part of the j -th column of A .

If $trans = 'N'$, $cnorm(j)$ must be greater than or equal to the infinity-norm, and if $trans = 'T'$ or $'C'$, $cnorm(j)$ must be greater than or equal to the 1-norm.

Output Parameters

scale

REAL for slatbs/clatbs

DOUBLE PRECISION for dlatbs/zlatbs.

The scaling factor s for the triangular system as described above. If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $Ax = 0$.

cnorm

If $normin = 'N'$, $cnorm$ is an output argument and

$cnorm(j)$ returns the 1-norm of the off-diagonal part of the j -th column of A .

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*k*, the *k*-th argument had an illegal value

?latdf

Uses the LU factorization of the n -by- n matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.

Syntax

```
call slatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call dlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call clatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call zlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?latdf uses the LU factorization of the n -by- n matrix Z computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate by solving $Z^*x = b$ for x , and choosing the right-hand side b such that the norm of x is as large as possible. On entry $rhs = b$ holds the contribution from earlier solved sub-systems, and on return $rhs = x$.

The factorization of Z returned by ?getc2 has the form $Z = P^*L^*U^*Q$, where P and Q are permutation matrices. L is lower triangular with unit diagonal elements and U is upper triangular.

Input Parameters

ijob INTEGER.
 ijob = 2: First compute an approximative null-vector e of Z using ?gecon, e is normalized, and solve for $Z^*x = \pm e - f$ with the sign giving the greater value of $2\text{-norm}(x)$. This option is about 5 times as expensive as default.
 ijob \neq 2 (default): Local look ahead strategy where all entries of the right-hand side b is chosen as either +1 or -1

<i>n</i>	INTEGER. The number of columns of the matrix <i>Z</i> .
<i>z</i>	REAL for slatdf/clatdf DOUBLE PRECISION for dlatdf/zlatdf. Array, DIMENSION (<i>ldz</i> , <i>n</i>) On entry, the <i>LU</i> part of the factorization of the <i>n</i> -by- <i>n</i> matrix <i>Z</i> computed by ?getc2: $Z = P*L*U*Q$.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>Z</i> . $lda \geq \max(1, n)$.
<i>rhs</i>	REAL for slatdf/clatdf DOUBLE PRECISION for dlatdf/zlatdf. Array, DIMENSION (<i>n</i>). On entry, <i>rhs</i> contains contributions from other subsystems.
<i>rdsum</i>	REAL for slatdf/clatdf DOUBLE PRECISION for dlatdf/zlatdf. On entry, the sum of squares of computed contributions to the Dif-estimate under computation by ?tgsyL, where the scaling factor <i>rdscal</i> has been factored out. If <i>trans</i> = 'T', <i>rdsum</i> is not touched. Note that <i>rdsum</i> only makes sense when ?tgsy2 is called by ?tgsyL.
<i>rdscal</i>	REAL for slatdf/clatdf DOUBLE PRECISION for dlatdf/zlatdf. On entry, scaling factor used to prevent overflow in <i>rdsum</i> . If <i>trans</i> = 'T', <i>rdscal</i> is not touched. Note that <i>rdscal</i> only makes sense when ?tgsy2 is called by ?tgsyL.
<i>ipiv</i>	INTEGER. Array, DIMENSION (<i>n</i>). The pivot indices; for $1 \leq i \leq n$, row <i>i</i> of the matrix has been interchanged with row <i>ipiv</i> (<i>i</i>).
<i>jpiv</i>	INTEGER. Array, DIMENSION (<i>n</i>). The pivot indices; for $1 \leq j \leq n$, column <i>j</i> of the matrix has been interchanged with column <i>jpiv</i> (<i>j</i>).

Output Parameters

<i>rhs</i>	On exit, <i>rhs</i> contains the solution of the subsystem with entries according to the value of <i>ijob</i> .
<i>rdsum</i>	On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If <i>trans</i> = 'T', <i>rdsum</i> is not touched.
<i>rdscal</i>	On exit, <i>rdscal</i> is updated with respect to the current contributions in <i>rdsum</i> . If <i>trans</i> = 'T', <i>rdscal</i> is not touched.

?latps

Solves a triangular system of equations with the matrix held in packed storage.

Syntax

```
call slatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call dlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call clatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call zlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?latps solves one of the triangular systems

$A*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem does not cause overflow, the Level 2 BLAS routine ?tpsv is called. If the matrix A is singular ($A(j, j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A*x = 0$ is returned.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular. = 'U': upper triangular = 'L': uower triangular</p>
<i>trans</i>	<p>CHARACTER*1. Specifies the operation applied to <i>A</i>. = 'N': solve $A * x = s * b$ (no transpose) = 'T': solve $A^T * x = s * b$ (transpose) = 'C': solve $A^H * x = s * b$ (conjugate transpose)</p>
<i>diag</i>	<p>CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular. = 'N': non-unit triangular = 'U': unit triangular</p>
<i>normin</i>	<p>CHARACTER*1. Specifies whether <i>cnorm</i> is set. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.</p>
<i>ap</i>	<p>REAL for slatps DOUBLE PRECISION for dlatps COMPLEX for clatps COMPLEX*16 for zlatps. Array, DIMENSION $(n(n+1)/2)$. The upper or lower triangular matrix <i>A</i>, packed columnwise in a linear array. The <i>j</i>-th column of <i>A</i> is stored in the array <i>ap</i> as follows: if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$; if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.</p>
<i>x</i>	<p>REAL for slatps DOUBLE PRECISION for dlatps COMPLEX for clatps COMPLEX*16 for zlatps.</p>

Array, DIMENSION (n)
 On entry, the right hand side b of the triangular system.

cnorm REAL for slatps/clatps
 DOUBLE PRECISION for dlatps/zlatps.
 Array, DIMENSION (n).
 If *normin* = 'Y', *cnorm* is an input argument and *cnorm*(j) contains the norm of the off-diagonal part of the j -th column of A .
 If *trans* = 'N', *cnorm*(j) must be greater than or equal to the infinity-norm, and if *trans* = 'T' or 'C', *cnorm*(j) must be greater than or equal to the 1-norm.

Output Parameters

x On exit, x is overwritten by the solution vector x .

scale REAL for slatps/clatps
 DOUBLE PRECISION for dlatps/zlatps.
 The scaling factor s for the triangular system as described above.
 If *scale* = 0, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $A*x = 0$.

cnorm If *normin* = 'N', *cnorm* is an output argument and *cnorm*(j) returns the 1-norm of the off-diagonal part of the j -th column of A .

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-k$, the k -th argument had an illegal value

?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call slatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call dlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call clatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call zlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?latrd` reduces nb rows and columns of a real symmetric or complex Hermitian matrix A to symmetric/Hermitian tridiagonal form by an orthogonal/unitary similarity transformation $Q^T A Q$ for real flavors, $Q^H A Q$ for complex flavors, and returns the matrices V and W which are needed to apply the transformation to the unreduced part of A .

If `uplo = 'U'`, `?latrd` reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if `uplo = 'L'`, `?latrd` reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by `?sytrd`/`?hetrd`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored: = 'U': upper triangular = 'L': lower triangular
<code>n</code>	INTEGER. The order of the matrix A .
<code>nb</code>	INTEGER. The number of rows and columns to be reduced.

a REAL for slatrd
 DOUBLE PRECISION for dlatrd
 COMPLEX for clatrd
 COMPLEX*16 for zlatrd.
 Array, DIMENSION (*lda*, *n*).
 On entry, the symmetric/Hermitian matrix *A*
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of
a contains the upper triangular part of the matrix *A*, and
 the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of
a contains the lower triangular part of the matrix *A*, and the
 strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*. *lda* ≥
 (1, *n*).

ldw INTEGER.
 The leading dimension of the output array *w*. *ldw* ≥
 max(1, *n*).

Output Parameters

a On exit, if *uplo* = 'U', the last *nb* columns have been
 reduced to tridiagonal form, with the diagonal elements
 overwriting the diagonal elements of *a*; the elements above
 the diagonal with the array *tau*, represent the
 orthogonal/unitary matrix *Q* as a product of elementary
 reflectors;
 if *uplo* = 'L', the first *nb* columns have been reduced to
 tridiagonal form, with the diagonal elements overwriting the
 diagonal elements of *a*; the elements below the diagonal
 with the array *tau*, represent the orthogonal/unitary matrix
Q as a product of elementary reflectors.

e REAL for slatrd/clatrd
 DOUBLE PRECISION for dlatrd/zlatrd.
 If *uplo* = 'U', *e*(*n*-*nb*:*n*-1) contains the superdiagonal
 elements of the last *nb* columns of the reduced matrix;
 if *uplo* = 'L', *e*(1:*nb*) contains the subdiagonal elements
 of the first *nb* columns of the reduced matrix.

tau REAL for slatrd
DOUBLE PRECISION for dlatrd
COMPLEX for clatrd
COMPLEX*16 for zlatrd.
Array, DIMENSION (*lda*, *n*).
The scalar factors of the elementary reflectors, stored in *tau*(*n-nb:n-1*) if *uplo* = 'U', and in *tau*(1:*nb*) if *uplo* = 'L'.

w REAL for slatrd
DOUBLE PRECISION for dlatrd
COMPLEX for clatrd
COMPLEX*16 for zlatrd.
Array, DIMENSION (*lda*, *n*).
The *n*-by-*nb* matrix *w* required to update the unreduced part of *A*.

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each *H*(*i*) has the form

$$H(i) = I - tau * v * v'$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(*i:n*) = 0 and *v*(*i-1*) = 1; *v*(1: *i-1*) is stored on exit in *a*(1: *i-1*, *i*), and *tau* in *tau*(*i-1*).

If *uplo* = 'L', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each *H*(*i*) has the form $H(i) = I - tau * v * v'$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(1: *i*) = 0 and *v*(*i+1*) = 1; *v*(*i+1:n*) is stored on exit in *a*(*i+1:n*, *i*), and *tau* in *tau*(*i*).

The elements of the vectors *v* together form the *n*-by-*nb* matrix *V* which is needed, with *w*, to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank-2k update of the form:

$$A := A - V W' - W V'.$$

The contents of *a* on exit are illustrated by the following examples with *n* = 5 and *nb* = 2:

$$\begin{array}{cc}
 \text{if } \text{uplo} = 'U': & \text{if } \text{uplo} = 'L' \\
 \begin{bmatrix} a & a & a & v_4 & v_4 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{bmatrix} & \begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{bmatrix}
 \end{array}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

```
call slatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call dlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call clatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call zlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine solves one of the triangular systems

$A^*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be

less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine `?trsv` is called. If the matrix A is singular ($A(j, j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A*x = 0$ is returned.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular</p>
<i>trans</i>	<p>CHARACTER*1. Specifies the operation applied to A. = 'N': solve $A*x = s*b$ (no transpose) = 'T': solve $A^T*x = s*b$ (transpose) = 'C': solve $A^{H}*x = s*b$ (conjugate transpose)</p>
<i>diag</i>	<p>CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': non-unit triangular = 'U': unit triangular</p>
<i>normin</i>	<p>CHARACTER*1. Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$</p>
<i>a</i>	<p>REAL for slatrs DOUBLE PRECISION for dlatrs COMPLEX for clatrs COMPLEX*16 for zlatrs. Array, DIMENSION (<i>lda</i>, <i>n</i>). Contains the triangular matrix A. If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If <i>uplo</i> = 'L', the leading n-by-n lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced.</p>

If *diag* = 'U', the diagonal elements of *A* are also not referenced and are assumed to be 1.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

x REAL for slatrs
DOUBLE PRECISION for dlatrs
COMPLEX for clatrs
COMPLEX*16 for zlatrs.
Array, DIMENSION (*n*).
On entry, the right hand side *b* of the triangular system.

cnorm REAL for slatrs/clatrs
DOUBLE PRECISION for dlatrs/zlatrs.
Array, DIMENSION (*n*).
If *normin* = 'Y', *cnorm* is an input argument and *cnorm* (*j*) contains the norm of the off-diagonal part of the *j*-th column of *A*.
If *trans* = 'N', *cnorm* (*j*) must be greater than or equal to the infinity-norm, and if *trans* = 'T' or 'C', *cnorm* (*j*) must be greater than or equal to the 1-norm.

Output Parameters

x On exit, *x* is overwritten by the solution vector *x*.

scale REAL for slatrs/clatrs
DOUBLE PRECISION for dlatrs/zlatrs.
Array, DIMENSION (*lda*, *n*). The scaling factor *s* for the triangular system as described above.
If *scale* = 0, the matrix *A* is singular or badly scaled, and the vector *x* is an exact or approximate solution to $A*x = 0$.

cnorm If *normin* = 'N', *cnorm* is an output argument and *cnorm* (*j*) returns the 1-norm of the off-diagonal part of the *j*-th column of *A*.

info INTEGER.
= 0: successful exit
< 0: if *info* = -*k*, the *k*-th argument had an illegal value

Application Notes

A rough bound on x is computed; if that is less than overflow, `?trsv` is called, otherwise, specific code is used which checks for possible overflow or divide-by-zero at every operation.

A columnwise scheme is used for solving $Ax = b$. The basic algorithm if A is lower triangular is

```
x[1:n] := b[1:n]
for j = 1, ..., n
  x(j) := x(j) / A(j,j)
  x[j+1:n] := x[j+1:n] - x(j)*a[j+1:n,j]
end
```

Define bounds on the components of x after j iterations of the loop:

```
M(j) = bound on x[1:j]
G(j) = bound on x[j+1:n]
```

Initially, let $M(0) = 0$ and $G(0) = \max\{x(i), i=1, \dots, n\}$.

Then for iteration $j+1$ we have

```
M(j+1) ≤ G(j) / | a(j+1,j+1) |
G(j+1) ≤ G(j) + M(j+1)*| a[j+2:n,j+1] |
≤ G(j) (1 + cnorm(j+1) / | a(j+1,j+1) |,
```

where $cnorm(j+1)$ is greater than or equal to the infinity-norm of column $j+1$ of a , not counting the diagonal. Hence

$$G(j) \leq G(0) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

and

$$|x(j)| \leq (G(0)/|A(j,j)|) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

Since $|x(j)| \leq M(j)$, we use the Level 2 BLAS routine `?trsv` if the reciprocal of the largest $M(j)$, $j=1, \dots, n$, is larger than $\max(\text{underflow}, 1/\text{overflow})$.

The bound on $x(j)$ is also used to determine when a step in the columnwise method can be performed without fear of overflow. If the computed bound is greater than a large constant, x is scaled to prevent overflow, but if the bound overflows, x is set to 0, $x(j)$ to 1, and scale to 0, and a non-trivial solution to $Ax = 0$ is found.

Similarly, a row-wise scheme is used to solve $A^T x = b$ or $A^H x = b$. The basic algorithm for A upper triangular is

```
for j = 1, ..., n
  x(j) := ( b(j) - A[1:j-1, j]' x[1:j-1] ) / A(j, j)
end
```

We simultaneously compute two bounds

$G(j)$ = bound on $(b(i) - A[1:i-1, i]' x[1:i-1])$, $1 \leq i \leq j$

$M(j)$ = bound on $x(i)$, $1 \leq i \leq j$

The initial values are $G(0) = 0$, $M(0) = \max\{ b(i), i=1, \dots, n \}$, and we add the constraint $G(j) \geq G(j-1)$ and $M(j) \geq M(j-1)$ for $j \geq 1$.

Then the bound on $x(j)$ is

$M(j) \leq M(j-1) * (1 + \text{cnorm}(j)) / |A(j, j)|$

$$\leq M(0) \prod_{1 \leq i \leq j} (1 + \text{cnorm}(i) / |A(i, i)|)$$

and we can safely call `?trsv` if $1/M(n)$ and $1/G(n)$ are both greater than $\max(\text{underflow}, 1/\text{overflow})$.

?latrz

Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.

Syntax

```
call slatz( m, n, l, a, lda, tau, work )
call dlatrz( m, n, l, a, lda, tau, work )
call clatz( m, n, l, a, lda, tau, work )
call zlatrz( m, n, l, a, lda, tau, work )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?latrz factors the m -by- $(m+1)$ real/complex upper trapezoidal matrix

$[A1 \ A2] = [A(1:m, 1:m) \ A(1:m, n-l+1:n)]$

as $(\begin{smallmatrix} R & 0 \end{smallmatrix})^* Z$, by means of orthogonal/unitary transformations. Z is an $(m+1)$ -by- $(m+1)$ orthogonal/unitary matrix and R and $A1$ are m -by- m upper triangular matrices.

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
l	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder vectors. $n-m \geq l \geq 0$.
a	REAL for slatz DOUBLE PRECISION for dlatrz COMPLEX for clatz COMPLEX*16 for zlatrz. Array, DIMENSION (lda, n). On entry, the leading m -by- n upper trapezoidal part of the array a must contain the matrix to be factorized.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, m)$.

work REAL for *slatz*
 DOUBLE PRECISION for *dlatz*
 COMPLEX for *clatz*
 COMPLEX*16 for *zlatrz*.
 Workspace array, DIMENSION (*m*).

Output Parameters

a On exit, the leading *m*-by-*m* upper triangular part of *a* contains the upper triangular matrix *R*, and elements *n-l+1* to *n* of the first *m* rows of *a*, with the array *tau*, represent the orthogonal/unitary matrix *Z* as a product of *m* elementary reflectors.

tau REAL for *slatz*
 DOUBLE PRECISION for *dlatz*
 COMPLEX for *clatz*
 COMPLEX*16 for *zlatrz*.
 Array, DIMENSION (*m*).
 The scalar factors of the elementary reflectors.

Application Notes

The factorization is obtained by Householder's method. The *k*-th transformation matrix, $z(k)$, which is used to introduce zeros into the (*m* - *k* + 1)-th row of *A*, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix}$$

where

$$T(k) = I - \tau u u^* u(k)^* T(k)^t, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an l -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of A_2 .

The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of A_2 , such that the elements of $z(k)$ are in $a(k, l+1), \dots, a(k, n)$.

The elements of r are returned in the upper triangular part of A_1 .

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

?lauu2

*Computes the product $U * U^T (U * U^H)$ or $L^T * L (L^H * L)$, where U and L are upper or lower triangular matrices (unblocked algorithm).*

Syntax

```
call slauu2( uplo, n, a, lda, info )
call dlauu2( uplo, n, a, lda, info )
call clauu2( uplo, n, a, lda, info )
call zlauu2( uplo, n, a, lda, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lauu2 computes the product $U * U^T$ or $L^T * L$ for real flavors, and $L^H * L$ or $L^H * L$ for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array a .

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in A .

If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in A .

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the triangular factor stored in the array <i>a</i> is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	INTEGER. The order of the triangular factor <i>U</i> or <i>L</i> . $n \geq 0$.
<i>a</i>	REAL for slauu2 DOUBLE PRECISION for dlauu2 COMPLEX for clauu2 COMPLEX*16 for zlauu2. Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the triangular factor <i>U</i> or <i>L</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', then the upper triangle of <i>a</i> is overwritten with the upper triangle of the product $U^*U^T(U^*U^H)$; if <i>uplo</i> = 'L', then the lower triangle of <i>a</i> is overwritten with the lower triangle of the product $L^T*L(L^H*L)$.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>k</i> , the <i>k</i> -th argument had an illegal value

?lauum

*Computes the product $U^*U^T(U^*U^H)$ or $L^T*L(L^H*L)$, where U and L are upper or lower triangular matrices (blocked algorithm).*

Syntax

```
call slauum( uplo, n, a, lda, info )
call dlauum( uplo, n, a, lda, info )
call clauum( uplo, n, a, lda, info )
call zlauum( uplo, n, a, lda, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lauum computes the product U^*U^T or L^T*L for real flavors, and L^H*L or L^H*L for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array a .

If `uplo` = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor U in A .

If `uplo` = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor L in A .

This is the blocked form of the algorithm, calling [BLAS Level 3 Routines](#).

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the triangular factor stored in the array a is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular
<code>n</code>	INTEGER. The order of the triangular factor U or L . $n \geq 0$.
<code>a</code>	REAL for slauum DOUBLE PRECISION for dlauum COMPLEX for clauum

COMPLEX*16 for `zlauum`.

Array, DIMENSION (`lda`, `n`).

On entry, the triangular factor U or L .

`lda`

INTEGER. The leading dimension of the array `a`. $lda \geq \max(1, n)$.

Output Parameters

`a`

On exit,

if `uplo` = 'U', then the upper triangle of `a` is overwritten with the upper triangle of the product $U^*U^T(U^*U^H)$;

if `uplo` = 'L', then the lower triangle of `a` is overwritten with the lower triangle of the product $L^T*L(L^H*L)$.

`info`

INTEGER.

= 0: successful exit

< 0: if `info` = $-k$, the k -th argument had an illegal value

?lazq3

Checks for deflation, computes a shift and calls `dqds`.

Syntax

```
call slazq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee,
  ttype, dmin1, dmin2, dn, dn1, dn2, tau )
```

```
call dlazq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee,
  ttype, dmin1, dmin2, dn, dn1, dn2, tau )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?lazq3` checks for deflation, computes a shift (`tau`) and calls `dqds`. In case of failure, it changes shifts, and tries again until output is positive.

This routine is a thread safe version of `?lasq3` routine, which passes `ttype`, `dmin1`, `dmin2`, `dn`, `dn1`, `dn2`, and `tau` through the argument list in place of declaring them in a `SAVE` statement.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for slasq3 DOUBLE PRECISION for dlasq3. Array, DIMENSION (4*n). <i>z</i> holds the <i>qd</i> array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>desig</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Lower order part of <i>sigma</i> .
<i>qmax</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Maximum value of <i>q</i> .
<i>ieee</i>	LOGICAL. Flag for IEEE or non-IEEE arithmetic (passed to the routine).
<i>ttype</i>	INTEGER. Shift type.
<i>dmin1</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) . Should be 0 on entry at the first iteration and should not be modified further.
<i>dmin2</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1) . Should be 0 on entry at the first iteration and should not be modified further.
<i>dn</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Contains <i>d</i> (<i>n</i>) . Should be 0 on entry at the first iteration and should not be modified further.
<i>dn1</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3.

	Contains $d(n-1)$. Should be 0 on entry at the first iteration and should not be modified further.
<i>dn2</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Contains $d(n-2)$. Should be 0 on entry at the first iteration and should not be modified further.
<i>tau</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Shift value

Output Parameters

<i>dmin</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Minimum value of d .
<i>sigma</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Sum of shifts used in current segment.
<i>desig</i>	Lower order part of <i>sigma</i> .
<i>nfail</i>	INTEGER. Number of times shift was too big.
<i>iter</i>	INTEGER. Number of iterations.
<i>ndiv</i>	INTEGER. Number of divisions.
<i>ttype</i>	Shift type.
<i>dmin1</i>	Minimum value of d , excluding $d(n_0)$.
<i>dmin2</i>	Minimum value of d , excluding $d(n_0)$ and $d(n_0-1)$.
<i>dn</i>	$d(n)$.
<i>dn1</i>	$d(n-1)$.
<i>dn2</i>	$d(n-2)$.
<i>tau</i>	Shift value.

?lazq4

Computes an approximation to the smallest eigenvalue using values of d from the previous transform.

Syntax

```
call slazq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau,
           ttype, g )
```

```
call dlazq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau,
           ttype, g )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes an approximation τ to the smallest eigenvalue using values of d from the previous transform.

This routine is a thread safe version of ?lasq4 routine, which passes g through the argument list in place of declaring g in a `SAVE` statement.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Array, DIMENSION (4*n). <i>z</i> holds the qd array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>n0in</i>	INTEGER. The value of <i>n0</i> at start of eigtest.
<i>dmin</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Minimum value of d .

<i>dmin1</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Minimum value of d , excluding $d(n0)$.
<i>dmin2</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Minimum value of d , excluding $d(n0)$ and $d(n0-1)$.
<i>dn</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Contains $d(n)$.
<i>dn1</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Contains $d(n-1)$.
<i>dn2</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Contains $d(n-2)$.
<i>g</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Shift coefficient.

Output Parameters

<i>tau</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Shift value.
<i>ttype</i>	INTEGER. Shift type.
<i>g</i>	Shift coefficient.

?org2l/?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by ?geqlf (unblocked algorithm).

Syntax

```
call sorg2l( m, n, k, a, lda, tau, work, info )
call dorg2l( m, n, k, a, lda, tau, work, info )
call cung2l( m, n, k, a, lda, tau, work, info )
call zung2l( m, n, k, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?org2l/?ung2l generates an m -by- n real/complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m :

$Q = H(k) * \dots * H(2) * H(1)$ as returned by ?geqlf.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $m \geq n \geq 0$.
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	REAL for sorg2l DOUBLE PRECISION for dorg2l COMPLEX for cung2l COMPLEX*16 for zung2l. Array, DIMENSION (lda, n).

On entry, the $(n - k + i)$ -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqlf in the last k columns of its array argument A .

lda INTEGER. The first dimension of the array a . $lda \geq \max(1, m)$.

tau REAL for sorg2l
DOUBLE PRECISION for dorg2l
COMPLEX for cung2l
COMPLEX*16 for zung2l.
Array, DIMENSION (k).
 $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqlf.

work REAL for sorg2l
DOUBLE PRECISION for dorg2l
COMPLEX for cung2l
COMPLEX*16 for zung2l.
Workspace array, DIMENSION (n).

Output Parameters

a On exit, the m -by- n matrix Q .

info INTEGER.
= 0: successful exit
< 0: if $info = -i$, the i -th argument has an illegal value

?org2r/?ung2r

Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by ?geqrf (unblocked algorithm).

Syntax

```
call sorg2r( m, n, k, a, lda, tau, work, info )
call dorg2r( m, n, k, a, lda, tau, work, info )
call cung2r( m, n, k, a, lda, tau, work, info )
call zung2r( m, n, k, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?org2r/?ung2r` generates an m -by- n real/complex matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `?geqrf`.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $m \geq n \geq 0$.
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	REAL for <code>sorg2r</code> DOUBLE PRECISION for <code>dorg2r</code> COMPLEX for <code>cung2r</code> COMPLEX*16 for <code>zung2r</code> . Array, DIMENSION (lda, n).

On entry, the i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqrf in the first k columns of its array argument a .

lda INTEGER. The first DIMENSION of the array a . $lda \geq \max(1, m)$.

tau REAL for sorg2r
DOUBLE PRECISION for dorg2r
COMPLEX for cung2r
COMPLEX*16 for zung2r.
Array, DIMENSION (k).
 $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqrf.

work REAL for sorg2r
DOUBLE PRECISION for dorg2r
COMPLEX for cung2r
COMPLEX*16 for zung2r.
Workspace array, DIMENSION (n).

Output Parameters

a On exit, the m -by- n matrix Q .

info INTEGER.
= 0: successful exit
< 0: if $info = -i$, the i -th argument has an illegal value

?orgl2/?ungl2

Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by ?gelqf (unblocked algorithm).

Syntax

```
call sorgl2( m, n, k, a, lda, tau, work, info )
call dorgl2( m, n, k, a, lda, tau, work, info )
call cungl2( m, n, k, a, lda, tau, work, info )
call zungl2( m, n, k, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?orgl2/?ungl2 generates a m -by- n real/complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = H(k) * \dots * H(2) * H(1)$ for real flavors, or $Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ for complex flavors as returned by ?gelqf.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $n \geq m$.
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for sorgl2 DOUBLE PRECISION for dorgl2 COMPLEX for cungl2 COMPLEX*16 for zungl2. Array, DIMENSION (lda, n). On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gelqf in the first k rows of its array argument a .

lda INTEGER. The first dimension of the array *a*. $lda \geq \max(1, m)$.

tau REAL for `sorgl2`
 DOUBLE PRECISION for `dorgl2`
 COMPLEX for `cungl2`
 COMPLEX*16 for `zungl2`.
 Array, DIMENSION (*k*).
tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by `?gelqf`.

work REAL for `sorgl2`
 DOUBLE PRECISION for `dorgl2`
 COMPLEX for `cungl2`
 COMPLEX*16 for `zungl2`.
 Workspace array, DIMENSION (*m*).

Output Parameters

a On exit, the *m*-by-*n* matrix *Q*.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument has an illegal value.

?org2/?ungr2

Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by ?gerqf (unblocked algorithm).

Syntax

```
call sorg2( m, n, k, a, lda, tau, work, info )
call dorg2( m, n, k, a, lda, tau, work, info )
call cungr2( m, n, k, a, lda, tau, work, info )
call zungr2( m, n, k, a, lda, tau, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?orgr2/?ungr2` generates an m -by- n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1) * H(2) * \dots * H(k)$ for real flavors, or $Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ for complex flavors as returned by `?gerqf`.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $n \geq m$
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for <code>sorgr2</code> DOUBLE PRECISION for <code>dorgr2</code> COMPLEX for <code>cungr2</code> COMPLEX*16 for <code>zungr2</code> . Array, DIMENSION (lda, n). On entry, the $(m - k + i)$ -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>?gerqf</code> in the last k rows of its array argument a .
lda	INTEGER. The first dimension of the array a . $lda \geq \max(1, m)$.
τ	REAL for <code>sorgr2</code> DOUBLE PRECISION for <code>dorgr2</code> COMPLEX for <code>cungr2</code> COMPLEX*16 for <code>zungr2</code> . Array, DIMENSION (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>?gerqf</code> .
$work$	REAL for <code>sorgr2</code> DOUBLE PRECISION for <code>dorgr2</code> COMPLEX for <code>cungr2</code>

COMPLEX*16 for `zungr2`.
 Workspace array, DIMENSION (m).

Output Parameters

a On exit, the m -by- n matrix Q .
info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-i$, the i -th argument has an illegal value

?orm2l/?unm2l

Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).

Syntax

```
call sorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?orm2l/?unm2l overwrites the general real/complex m -by- n matrix C with

Q^*C if *side* = 'L' and *trans* = 'N', or

$Q^T C / Q^H C$ if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

C^*Q if *side* = 'R' and *trans* = 'N', or

C^*Q^T / C^*Q^H if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by ?geqlf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	INTEGER. The number of rows of the matrix C . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix C . $n \geq 0$.
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	REAL for sorm2l DOUBLE PRECISION for dorm2l COMPLEX for cunm2l COMPLEX*16 for zunm2l. Array, DIMENSION (lda, k). The i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqlf in the last k columns of its array argument a . The array a is modified by the routine but restored on exit.
<i>lda</i>	INTEGER. The leading dimension of the array a . If $side = 'L'$, $lda \geq \max(1, m)$ if $side = 'R'$, $lda \geq \max(1, n)$.
<i>tau</i>	REAL for sorm2l DOUBLE PRECISION for dorm2l COMPLEX for cunm2l COMPLEX*16 for zunm2l.

Array, DIMENSION (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqlf.

c REAL for sorm2l
 DOUBLE PRECISION for dorm2l
 COMPLEX for cunm2l
 COMPLEX*16 for zunm2l.
 Array, DIMENSION (ldc, n).
 On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array C . $ldc \geq \max(1, m)$.

work REAL for sorm2l
 DOUBLE PRECISION for dorm2l
 COMPLEX for cunm2l
 COMPLEX*16 for zunm2l.
 Workspace array, DIMENSION:
 (n) if $side = 'L'$,
 (m) if $side = 'R'$.

Output Parameters

c On exit, c is overwritten by Q^*C or $Q^T * C / Q^H * C$, or C^*Q , or C^*Q^T / C^*Q^H .

info INTEGER.
 = 0: successful exit
 < 0: if $info = -i$, the i -th argument had an illegal value

?orm2r/?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).

Syntax

```
call sorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?orm2r/?unm2r overwrites the general real/complex m -by- n matrix C with

Q^*C if $side = 'L'$ and $trans = 'N'$, or

$Q^T * C / Q^H * C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$C * Q$ if $side = 'R'$ and $trans = 'N'$, or

$C * Q^T / C * Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ as returned by ?geqrf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1.

= 'N': apply Q (no transpose)
 = 'T': apply Q^T (transpose, for real flavors)
 = 'C': apply Q^H (conjugate transpose, for complex flavors)

m INTEGER. The number of rows of the matrix C . $m \geq 0$.

n INTEGER. The number of columns of the matrix C . $n \geq 0$.

k INTEGER. The number of elementary reflectors whose product defines the matrix Q .
 If $side = 'L'$, $m \geq k \geq 0$;
 if $side = 'R'$, $n \geq k \geq 0$.

a REAL for sorm2r
 DOUBLE PRECISION for dorm2r
 COMPLEX for cunm2r
 COMPLEX*16 for zunm2r.
 Array, DIMENSION (lda, k).
 The i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqrf in the first k columns of its array argument a .
 The array a is modified by the routine but restored on exit.

lda INTEGER. The leading dimension of the array a .
 If $side = 'L'$, $lda \geq \max(1, m)$;
 if $side = 'R'$, $lda \geq \max(1, n)$.

tau REAL for sorm2r
 DOUBLE PRECISION for dorm2r
 COMPLEX for cunm2r
 COMPLEX*16 for zunm2r.
 Array, DIMENSION (k).
tau(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqrf.

c REAL for sorm2r
 DOUBLE PRECISION for dorm2r
 COMPLEX for cunm2r
 COMPLEX*16 for zunm2r.
 Array, DIMENSION (ldc, n).
 On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array *c*. $ldc \geq \max(1, m)$.

work REAL for sorm2r
 DOUBLE PRECISION for dorm2r
 COMPLEX for cunm2r
 COMPLEX*16 for zunm2r.
 Workspace array, DIMENSION
 (*n*) if *side* = 'L',
 (*m*) if *side* = 'R'.

Output Parameters

c On exit, *c* is overwritten by Q^*C or $Q^T * C / Q^H * C$, or $C * Q$, or $C * Q^T / C * Q^H$.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value

?orml2/?unml2

Multiplies a general matrix by the orthogonal/unitary matrix from a LQ factorization determined by ?gelqf (unblocked algorithm).

Syntax

```
call sorml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?orml2/?unml2 overwrites the general real/complex *m*-by-*n* matrix *C* with Q^*C if *side* = 'L' and *trans* = 'N', or

$Q^T * C / Q^H * C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$C * Q$ if $side = 'R'$ and $trans = 'N'$, or

$C * Q^T / C * Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ for real flavors, or $Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ for complex flavors as returned by `?gelqf`.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	INTEGER. The number of rows of the matrix C . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix C . $n \geq 0$.
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	REAL for <code>sorml2</code> DOUBLE PRECISION for <code>dorml2</code> COMPLEX for <code>cunml2</code> COMPLEX*16 for <code>zunml2</code> . Array, DIMENSION (<i>lda</i> , <i>m</i>) if $side = 'L'$, (<i>lda</i> , <i>n</i>) if $side = 'R'$

The i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gelqf in the first k rows of its array argument a . The array a is modified by the routine but restored on exit.

<i>lda</i>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, k)$.
<i>tau</i>	REAL for sorml2 DOUBLE PRECISION for dorml2 COMPLEX for cunml2 COMPLEX*16 for zunml2. Array, DIMENSION (k). $tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?gelqf.

call cunmr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunmr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?ormr2/?unmr2 overwrites the general real/complex m -by- n matrix C with

Q^*C if $side = 'L'$ and $trans = 'N'$, or

$Q^T C / Q^H C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

C^*Q if $side = 'R'$ and $trans = 'N'$, or

C^*Q^T / C^*Q^H if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ for real flavors, or $Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ as returned by ?gerqf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side CHARACTER*1.
 = 'L': apply Q or Q^T / Q^H from the left
 = 'R': apply Q or Q^T / Q^H from the right

trans CHARACTER*1.
= 'N': apply Q (no transpose)
= 'T': apply Q^T (transpose, for real flavors)
= 'C': apply Q^H (conjugate transpose, for complex flavors)

m INTEGER. The number of rows of the matrix C . $m \geq 0$.

n INTEGER. The number of columns of the matrix C . $n \geq 0$.

k INTEGER. The number of elementary reflectors whose product defines the matrix Q .
If *side* = 'L', $m \geq k \geq 0$;
if *side* = 'R', $n \geq k \geq 0$.

a REAL for sormr2
DOUBLE PRECISION for dormr2
COMPLEX for cunmr2
COMPLEX*16 for zunmr2.
Array, DIMENSION
(*lda*, *m*) if *side* = 'L',
(*lda*, *n*) if *side* = 'R'
The *i*-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gerqf in the last *k* rows of its array argument *a*. The array *a* is modified by the routine but restored on exit.

lda INTEGER.
The leading dimension of the array *a*. $lda \geq \max(1, k)$.

tau REAL for sormr2
DOUBLE PRECISION for dormr2
COMPLEX for cunmr2
COMPLEX*16 for zunmr2.
Array, DIMENSION (*k*).
tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?gerqf.

c REAL for sormr2
DOUBLE PRECISION for dormr2
COMPLEX for cunmr2
COMPLEX*16 for zunmr2.
Array, DIMENSION (*ldc*, *n*).

On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.

work REAL for sormr2
 DOUBLE PRECISION for dormr2
 COMPLEX for cunmr2
 COMPLEX*16 for zunmr2.
 Workspace array, DIMENSION
 (n) if *side* = 'L',
 (m) if *side* = 'R'

Output Parameters

c On exit, c is overwritten by Q^*C or Q^T*C / Q^H*C , or $C*Q$, or $C*Q^T / C*Q^H$.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-i$, the i -th argument had an illegal value

?ormr3/?unmr3

Multiplies a general matrix by the orthogonal/unitary matrix from a RZ factorization determined by ?tzzrf (unblocked algorithm).

Syntax

```
call sormr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call dormr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call cunmr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call zunmr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine ?ormr3/?unmr3 overwrites the general real/complex m -by- n matrix C with

$Q^T C$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T C / Q^H C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$C Q$ if $side = 'R'$ and $trans = 'N'$, or

$C Q^T / C Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ as returned by `?tzrzf`.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	INTEGER. The number of rows of the matrix C . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix C . $n \geq 0$.
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$.
<i>l</i>	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If $side = 'L'$, $m \geq l \geq 0$, if $side = 'R'$, $n \geq l \geq 0$.
<i>a</i>	REAL for <code>sormr3</code> DOUBLE PRECISION for <code>dormr3</code> COMPLEX for <code>cunmr3</code>

	COMPLEX*16 for zunmr3. Array, DIMENSION (lda, m) if side = 'L', (lda, n) if side = 'R' The i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?tzrzf in the last k rows of its array argument a . The array a is modified by the routine but restored on exit.
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(1, k)$.
tau	REAL for sormr3 DOUBLE PRECISION for dormr3 COMPLEX for cunmr3 COMPLEX*16 for zunmr3. Array, DIMENSION (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?tzrzf.
c	REAL for sormr3 DOUBLE PRECISION for dormr3 COMPLEX for cunmr3 COMPLEX*16 for zunmr3. Array, DIMENSION (ldc, n). On entry, the m -by- n matrix C .
ldc	INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.
work	REAL for sormr3 DOUBLE PRECISION for dormr3 COMPLEX for cunmr3 COMPLEX*16 for zunmr3. Workspace array, DIMENSION (n) if side = 'L', (m) if side = 'R'.

Output Parameters

c	On exit, c is overwritten by Q^*C or $Q^T * C$ / $Q^{H*}C$, or C^*Q , or C^*Q^T / C^*Q^H .
-----	-------------------------------------------------------------------------------------------------------

INTEGER.
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value

?pbt2

Computes the Cholesky factorization of a symmetric/ Hermitian positive-definite band matrix (unblocked algorithm).

Syntax

```
call spbtf2( uplo, n, kd, ab, ldab, info )
call dpbtf2( uplo, n, kd, ab, ldab, info )
call cpbtf2( uplo, n, kd, ab, ldab, info )
call zpbtf2( uplo, n, kd, ab, ldab, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite band matrix A .

The factorization has the form

$A = U^T \star U$ for real flavors, $A = U^H \star U$ for complex flavors if `uplo = 'U'`, or

$$A = L^* L^T \text{ for real flavors, } A = L^* L^H \text{ for complex flavors if } uplo = 'L',$$

where U is an upper triangular matrix, and L is lower triangular. This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix <i>A</i> is stored: = 'U': upper triangular = 'L': lower triangular
-------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

n INTEGER. The order of the matrix A . $n \geq 0$.

<i>kd</i>	<p>INTEGER. The number of super-diagonals of the matrix <i>A</i> if <i>uplo</i> = 'U' , or the number of sub-diagonals if <i>uplo</i> = 'L'.</p> <p>$kd \geq 0$.</p>
<i>ab</i>	<p>REAL for spbtf2 DOUBLE PRECISION for dpbtf2 COMPLEX for cpbtf2 COMPLEX*16 for zpbtf2. Array, DIMENSION (<i>ldab</i>, <i>n</i>). On entry, the upper or lower triangle of the symmetric/ Hermitian band matrix <i>A</i>, stored in the first <i>kd</i>+1 rows of the array. The <i>j</i>-th column of <i>A</i> is stored in the <i>j</i>-th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(kd+1+i-j, j) = A(i, j \text{ for } \max(1, j-kd) \leq i \leq j$; if <i>uplo</i> = 'L', $ab(1+i-j, j) = A(i, j \text{ for } j \leq i \leq \min(n, j+kd)$.</p>
<i>ldab</i>	<p>INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq kd+1$.</p>

Output Parameters

<i>ab</i>	<p>On exit, If <i>info</i> = 0, the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A=U^T*U$ ($A=U^H*U$), or $A= L*L^T$ ($A = L*L^H$) of the band matrix <i>A</i>, in the same storage format as <i>A</i>.</p>
<i>info</i>	<p>INTEGER. = 0: successful exit < 0: if <i>info</i> = -<i>k</i>, the <i>k</i>-th argument had an illegal value > 0: if <i>info</i> = <i>k</i>, the leading minor of order <i>k</i> is not positive definite, and the factorization could not be completed.</p>

?potf2

Computes the Cholesky factorization of a symmetric/Hermitian positive-definite matrix (unblocked algorithm).

Syntax

```
call spotf2( uplo, n, a, lda, info )
call dpotf2( uplo, n, a, lda, info )
call cpotf2( uplo, n, a, lda, info )
call zpotf2( uplo, n, a, lda, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?potf2 computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite matrix A . The factorization has the form

$A = U^T * U$ for real flavors, $A = U^H * U$ for complex flavors if `uplo = 'U'`, or

$A = L * L^T$ for real flavors, $A = L * L^H$ for complex flavors if `uplo = 'L'`,

where U is an upper triangular matrix, and L is lower triangular.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#)

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored. = 'U': upper triangular = 'L': lower triangular
<code>n</code>	INTEGER. The order of the matrix A . $n \geq 0$.
<code>a</code>	REAL for spotf2 DOUBLE PRECISION or dpotf2 COMPLEX for cpotf2 COMPLEX*16 for zpotf2.

Array, DIMENSION (lda, n).

On entry, the symmetric/Hermitian matrix A .

If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER. The leading dimension of the array a .

$lda \geq \max(1, n)$.

Output Parameters

a On exit, If $info = 0$, the factor U or L from the Cholesky factorization $A=U^T*U$ ($A=U^H*U$), or $A= L*L^T$ ($A = L*L^H$).

$info$ INTEGER.

= 0: successful exit

< 0: if $info = -k$, the k -th argument had an illegal value

> 0: if $info = k$, the leading minor of order k is not positive definite, and the factorization could not be completed.

?ptts2

*Solves a tridiagonal system of the form $A*X=B$ using the $L*D*L^H/L*D*L^H$ factorization computed by ?pttrf.*

Syntax

```
call sptts2( n, nrhs, d, e, b, ldb )
call dptts2( n, nrhs, d, e, b, ldb )
call cptts2( iuplo, n, nrhs, d, e, b, ldb )
call zptts2( iuplo, n, nrhs, d, e, b, ldb )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?ptts2` solves a tridiagonal system of the form

$$A * X = B$$

Real flavors `sptts2/dptts2` use the $L^*D^*L^T$ factorization of A computed by `spttrf/dpttrf`, and complex flavors `cptts2/zptts2` use the U^H*D*U or $L^*D^*L^H$ factorization of A computed by `cpttrf/zpttrf`.

D is a diagonal matrix specified in the vector d , U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector e , and X and B are n -by- $nrhs$ matrices.

Input Parameters

<i>iuplo</i>	<p>INTEGER. Used with complex flavors only.</p> <p>Specifies the form of the factorization, and whether the vector e is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L.</p> <p>= 1: $A = U^H * D * U$, e is the superdiagonal of U;</p> <p>= 0: $A = L * D * L^H$, e is the subdiagonal of L</p>
<i>n</i>	<p>INTEGER. The order of the tridiagonal matrix A. $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right hand sides, that is, the number of columns of the matrix B. $nrhs \geq 0$.</p>
<i>d</i>	<p>REAL for <code>sptts2/cptts2</code></p> <p>DOUBLE PRECISION for <code>dptts2/zptts2</code>.</p> <p>Array, DIMENSION (n).</p> <p>The n diagonal elements of the diagonal matrix D from the factorization of A.</p>
<i>e</i>	<p>REAL for <code>sptts2</code></p> <p>DOUBLE PRECISION for <code>dptts2</code></p> <p>COMPLEX for <code>cptts2</code></p> <p>COMPLEX*16 for <code>zptts2</code>.</p> <p>Array, DIMENSION ($n-1$).</p> <p>Contains the ($n-1$) subdiagonal elements of the unit bidiagonal factor L from the $L^*D^*L^T$ (for real flavors) or $L^*D^*L^H$ (for complex flavors when <code>iuplo</code> = 0) factorization of A.</p> <p>For complex flavors when <code>iuplo</code> = 1, e contains the ($n-1$) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U^H * D * U$.</p>

B REAL for sptts2/cptts2
 DOUBLE PRECISION for dptts2/zptts2.
 Array, DIMENSION (*ldb*, *nrhs*).
 On entry, the right hand side vectors *B* for the system of linear equations.

ldb INTEGER. The leading dimension of the array *B*. $ldb \geq \max(1, n)$.

Output Parameters

b On exit, the solution vectors, *x*.

?rscl

Multiplies a vector by the reciprocal of a real scalar.

Syntax

```
call srscl( n, sa, sx, incx )
call drscl( n, sa, sx, incx )
call csrscl( n, sa, sx, incx )
call zdrscl( n, sa, sx, incx )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?rscl` multiplies an n -element real/complex vector x by the real scalar $1/a$. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Input Parameters

n INTEGER. The number of components of the vector x .

sa REAL for srscl/csrscl
 DOUBLE PRECISION for drscl/zdrscl.

The scalar a which is used to divide each component of the vector x . sa must be ≥ 0 , or the subroutine will divide by zero.

<i>sx</i>	REAL for <i>srscl</i> DOUBLE PRECISION for <i>drsc1</i> COMPLEX for <i>csrscl</i> COMPLEX*16 for <i>zdrsc1</i> . Array, DIMENSION $(1+(n-1) * incx)$. The n -element vector x .
<i>incx</i>	INTEGER. The increment between successive values of the vector sx . If $incx > 0$, $sx(1)=x(1)$, and $sx(1+(i-1)*incx)=x(i)$, $1 < i \leq n$.

Output Parameters

<i>sx</i>	On exit, the result x/a .
-----------	-----------------------------

?sygs2/?hegs2

Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).

Syntax

```
call ssygs2( itype, uplo, n, a, lda, b, ldb, info )
call dsygs2( itype, uplo, n, a, lda, b, ldb, info )
call chs2( itype, uplo, n, a, lda, b, ldb, info )
call zhegs2( itype, uplo, n, a, lda, b, ldb, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?sygs2/?hegs2` reduces a real symmetric-definite or a complex Hermitian-definite generalized eigenproblem to standard form.

If $itype = 1$, the problem is

$$A*x = \lambda*B*x$$

and A is overwritten by $\text{inv}(U')*A*\text{inv}(U)$, or $\text{inv}(L)*A*\text{inv}(L')$.

If $itype = 2$ or 3 , the problem is

$$A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x,$$

and A is overwritten by $U*A*U'$ or $L'*A*L$. Here U' (L') is the transpose (conjugate transpose) of U (L).

B must be previously factorized as $U'*U$ or $L*L'$ by ?potrf.

Input Parameters

itype INTEGER.
 = 1: compute $\text{inv}(U')*A*\text{inv}(U)$, or $\text{inv}(L)*A*\text{inv}(L')$;
 = 2 or 3: compute $U*A*U'$, or $L'*A*L$.

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored, and how B has been factorized.
 = 'U': upper triangular
 = 'L': lower triangular

n INTEGER. The order of the matrices A and B . $n \geq 0$.

a REAL for ssygs2
 DOUBLE PRECISION for dsygs2
 COMPLEX for chesgs2
 COMPLEX*16 for zhesgs2.
 Array, DIMENSION (lda , n).
 On entry, the symmetric/Hermitian matrix A .
 If *uplo* = 'U', the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.
 If *uplo* = 'L', the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER.
 The leading dimension of the array a . $lda \geq \max(1, n)$.

b REAL for ssygs2
DOUBLE PRECISION for dsygs2
COMPLEX for chegs2
COMPLEX*16 for zhegs2.
Array, DIMENSION (*ldb*, *n*).
The triangular factor from the Cholesky factorization of *B*
as returned by ?potrf.

ldb INTEGER. The leading dimension of the array *b*. $ldb \geq \max(1, n)$.

Output Parameters

a On exit, If *info* = 0, the transformed matrix, stored in the
same format as *A*.

info INTEGER.
= 0: successful exit.
< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?sytd2/?hetd2

*Reduces a symmetric/Hermitian matrix to real
symmetric tridiagonal form by an
orthogonal/unitary similarity
transformation(unblocked algorithm).*

Syntax

```
call ssytd2( uplo, n, a, lda, d, e, tau, info )
call dsytd2( uplo, n, a, lda, d, e, tau, info )
call chetd2( uplo, n, a, lda, d, e, tau, info )
call zhetd2( uplo, n, a, lda, d, e, tau, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine `?sytd2/?hetd2` reduces a real symmetric/complex Hermitian matrix A to real symmetric tridiagonal form T by an orthogonal/unitary similarity transformation: $Q^T A Q = T$ ($Q^H A Q = T$).

Input Parameters

uplo CHARACTER*1.
Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored:
= 'U': upper triangular
= 'L': lower triangular

n INTEGER. The order of the matrix A . $n \geq 0$.

a REAL for `ssytd2`
DOUBLE PRECISION for `dsytd2`
COMPLEX for `chetd2`
COMPLEX*16 for `zhetd2`.
Array, DIMENSION (*lda*, *n*).
On entry, the symmetric/Hermitian matrix A .
If *uplo* = 'U', the leading n -by- n upper triangular part of *a* contains the upper triangular part of the matrix A , and the strictly lower triangular part of *a* is not referenced.
If *uplo* = 'L', the leading n -by- n lower triangular part of *a* contains the lower triangular part of the matrix A , and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, if *uplo* = 'U', the diagonal and first superdiagonal of *a* are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors;

if *uplo* = 'L', the diagonal and first subdiagonal of *a* are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors.

d

REAL for ssytd2/chetd2
DOUBLE PRECISION for dsytd2/zhetd2.

Array, DIMENSION (*n*).

The diagonal elements of the tridiagonal matrix *T*:

$d(i) = a(i, i)$.

e

REAL for ssytd2/chetd2
DOUBLE PRECISION for dsytd2/zhetd2.

Array, DIMENSION (*n*-1).

The off-diagonal elements of the tridiagonal matrix *T*:

$e(i) = a(i, i+1)$ if *uplo* = 'U',

$e(i) = a(i+1, i)$ if *uplo* = 'L'.

tau

REAL for ssytd2
DOUBLE PRECISION for dsytd2
COMPLEX for chetd2
COMPLEX*16 for zhetd2.

Array, DIMENSION (*n*).

The first *n*-1 elements contain scalar factors of the elementary reflectors. *tau*(*n*) is used as workspace.

info

INTEGER.

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?sytf2

Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call ssytf2( uplo, n, a, lda, ipiv, info )
call dsytf2( uplo, n, a, lda, ipiv, info )
call csytf2( uplo, n, a, lda, ipiv, info )
call zsytf2( uplo, n, a, lda, ipiv, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?sytf2 computes the factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D^* U^T (A = U^* D^* U^H), \text{ or } A = L^* D^* L^T (A = L^* D^* L^H),$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored = 'U': upper triangular = 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>a</i>	REAL for ssytf2 DOUBLE PRECISION for dsytf2 COMPLEX for csytf2 COMPLEX*16 for zsytf2. Array, DIMENSION (<i>lda</i> , <i>n</i>).

On entry, the symmetric matrix A .

If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda

INTEGER.

The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

a

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L .

ipiv

INTEGER.

Array, DIMENSION (n).

Details of the interchanges and the block structure of D

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ are interchanged and $D(k,k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ are interchanged and $D(k,k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

< 0: if $info = -k$, the k -th argument has an illegal value

> 0: if $info = k$, $D(k,k)$ is exactly zero. The factorization are completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

zhetf2

Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call chetf2( uplo, n, a, lda, ipiv, info )
call zhetf2( uplo, n, a, lda, ipiv, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D^* U' \text{ or } A = L^* D^* L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the conjugate transpose of U , and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular
<code>n</code>	INTEGER. The order of the matrix A . $n \geq 0$.
<code>A</code>	COMPLEX for <code>chetf2</code> COMPLEX*16 for <code>zhetf2</code> . Array, DIMENSION (<code>lda</code> , <code>n</code>). On entry, the Hermitian matrix A . If <code>uplo</code> = 'U', the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced.

If `uplo = 'L'`, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

`lda`

INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

`a`

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L .

`ipiv`

INTEGER. Array, DIMENSION (n).

Details of the interchanges and the block structure of D

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

`info`

INTEGER.

= 0: successful exit

< 0: if $info = -k$, the k -th argument had an illegal value

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?tgex2

Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.

Syntax

```
call stgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2,
work, lwork, info )

call dtgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2,
work, lwork, info )

call ctgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
call ztgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The real routines `stgex2/dtgex2` swap adjacent diagonal blocks (A_{11} , B_{11}) and (A_{22} , B_{22}) of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair (A , B) by an orthogonal equivalence transformation. (A , B) must be in generalized real Schur canonical form (as returned by `sgges/dgges`), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex routines `ctgex2/ztgex2` swap adjacent diagonal 1-by-1 blocks (A_{11} , B_{11}) and (A_{22} , B_{22}) in an upper triangular matrix pair (A , B) by an unitary equivalence transformation.

(A , B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

All routines optionally update the matrices Q and Z of generalized Schur vectors:

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})' = Q(\text{out}) * A(\text{out}) * Z(\text{out})'$$

$Q(\text{in}) * B(\text{in}) * Z(\text{in})' = Q(\text{out}) * B(\text{out}) * Z(\text{out})'$, where Z' is the transpose (conjugate transpose) of Z .

Input Parameters

`wantq` LOGICAL.
 If `wantq = .TRUE.` : update the left transformation matrix Q ;

<i>wantz</i>	<p>If <i>wantq</i> = .FALSE. : do not update <i>Q</i>.</p> <p>LOGICAL.</p> <p>If <i>wantz</i> = .TRUE. : update the right transformation matrix <i>Z</i>;</p> <p>If <i>wantz</i> = .FALSE. : do not update <i>Z</i>.</p>
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> . $n \geq 0$.
<i>a, b</i>	<p>REAL for stgex2 DOUBLE PRECISION for dtgex2</p> <p>COMPLEX for ctgex2</p> <p>COMPLEX*16 for ztgex2.</p> <p>Arrays, DIMENSION (<i>lda</i>, <i>n</i>) and (<i>ldb</i>, <i>n</i>), respectively.</p> <p>On entry, the matrices <i>A</i> and <i>B</i> in the pair (<i>A</i>, <i>B</i>).</p>
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> . $ldb \geq \max(1, n)$.
<i>q, z</i>	<p>REAL for stgex2 DOUBLE PRECISION for dtgex2</p> <p>COMPLEX for ctgex2</p> <p>COMPLEX*16 for ztgex2.</p> <p>Arrays, DIMENSION (<i>ldq</i>, <i>n</i>) and (<i>ldz</i>, <i>n</i>), respectively.</p> <p>On entry, if <i>wantq</i> = .TRUE., <i>q</i> contains the orthogonal/unitary matrix <i>Q</i>, and if <i>wantz</i> = .TRUE., <i>z</i> contains the orthogonal/unitary matrix <i>Z</i>.</p>
<i>ldq</i>	<p>INTEGER. The leading dimension of the array <i>q</i>. $ldq \geq 1$.</p> <p>If <i>wantq</i> = .TRUE., $ldq \geq n$.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the array <i>z</i>. $ldz \geq 1$.</p> <p>If <i>wantz</i> = .TRUE., $ldz \geq n$.</p>
<i>j1</i>	<p>INTEGER.</p> <p>The index to the first block (<i>A11</i>, <i>B11</i>). $1 \leq j1 \leq n$.</p>
<i>n1</i>	INTEGER. Used with real flavors only. The order of the first block (<i>A11</i> , <i>B11</i>). $n1 = 0, 1$ or 2 .
<i>n2</i>	INTEGER. Used with real flavors only. The order of the second block (<i>A22</i> , <i>B22</i>). $n2 = 0, 1$ or 2 .

work REAL for stgex2
DOUBLE PRECISION for dtgex2.
Workspace array, DIMENSION (max(1, *lwork*)). Used with
real flavors only.

lwork INTEGER. The dimension of the array *work*.
 $lwork \geq \max(n * (n2 + n1), 2 * (n2 + n1)^2)$

Output Parameters

a On exit, the updated matrix *A*.

B On exit, the updated matrix *B*.

Q On exit, the updated matrix *Q*.
Not referenced if *wantq* = .FALSE..

z On exit, the updated matrix *Z*.
Not referenced if *wantz* = .FALSE..

info INTEGER.
=0: Successful exit For stgex2/dtgex2: If *info* = 1, the
transformed matrix (*A*, *B*) would be too far from generalized
Schur form; the blocks are not swapped and (*A*, *B*) and (*Q*,
Z) are unchanged. The problem of swapping is too
ill-conditioned. If *info* = -16: *lwork* is too small.
Appropriate value for *lwork* is returned in *work*(1).
For ctgex2/ztgex2:
If *info* = 1, the transformed matrix pair (*A*, *B*) would be
too far from generalized Schur form; the problem is
ill-conditioned.

?tgssy2

Solves the generalized Sylvester equation (unblocked algorithm).

Syntax

```
call stgssy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
ldf, scale, rdsum, rdscal, iwork, pq, info )

call dtgssy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
ldf, scale, rdsum, rdscal, iwork, pq, info )

call ctgssy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
ldf, scale, rdsum, rdscal, iwork, pq, info )

call ztgssy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
ldf, scale, rdsum, rdscal, iwork, pq, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?tgssy2 solves the generalized Sylvester equation:

$$A^*R - L^*B = scale^*C \quad (1)$$

$$D^*R - L^*E = scale^*F$$

using Level 1 and 2 BLAS, where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively. For `stgssy2/dtgssy2`, pairs (A, D) and (B, E) must be in generalized Schur canonical form, that is, A, B are upper quasi triangular and D, E are upper triangular. For `ctgssy2/ztgssy2`, matrices A, B, D and E are upper triangular (that is, (A, D) and (B, E) in generalized Schur form).

The solution (R, L) overwrites (C, F) .

$0 \leq scale \leq 1$ is an output scaling factor chosen to avoid overflow.

In matrix notation, solving equation (1) corresponds to solve

$$Z^*x = scale^*b$$

where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix} \quad (2)$$

Here I_k is the identity matrix of size k and x' is the transpose (conjugate transpose) of x . $\text{kron}(X, Y)$ denotes the Kronecker product between the matrices X and Y .

If $trans = 'T'$, solve the transposed (conjugate transposed) system

$$Z' * y = scale * b$$

for y , which is equivalent to solve for R and L in

$$A' * R + D' * L = scale * C \quad (3)$$

$$R * B' + L * E' = scale * (-F)$$

This case is used to compute an estimate of $\text{Dif}[(A, D), (B, E)] = \text{sigma_min}(Z)$ using reverse communication with [?lacon](#).

`?tgssyl2` also (for $ijob \geq 1$) contributes to the computation in `?tgssyl` of an upper bound on the separation between two matrix pairs. Then the input (A, D) , (B, E) are sub-pencils of the matrix pair (two matrix pairs) in `?tgssyl`. See [?tgssyl](#) for details.

Input Parameters

trans CHARACTER*1.
If *trans* = 'N', solve the generalized Sylvester equation (1);
If *trans* = 'T': solve the 'transposed' system (3).

ijob INTEGER. Specifies what kind of functionality is to be performed.
If *ijob* = 0: solve (1) only.
If *ijob* = 1: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (look ahead strategy is used);
If *ijob* = 2: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (`?gecon` on sub-systems is used).
Not referenced if *trans* = 'T'.

<i>m</i>	INTEGER. On entry, <i>m</i> specifies the order of <i>A</i> and <i>D</i> , and the row dimension of <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> .
<i>n</i>	INTEGER. On entry, <i>n</i> specifies the order of <i>B</i> and <i>E</i> , and the column dimension of <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> .
<i>a</i> , <i>b</i>	REAL for stgsy2 DOUBLE PRECISION for dtgsy2 COMPLEX for ctgsy2 COMPLEX*16 for ztgsy2. Arrays, DIMENSION (<i>lda</i> , <i>m</i>) and (<i>ldb</i> , <i>n</i>), respectively. On entry, <i>a</i> contains an upper (quasi) triangular matrix <i>A</i> , and <i>b</i> contains an upper (quasi) triangular matrix <i>B</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> . $ldb \geq \max(1, n)$.
<i>c</i> , <i>f</i>	REAL for stgsy2 DOUBLE PRECISION for dtgsy2 COMPLEX for ctgsy2 COMPLEX*16 for ztgsy2. Arrays, DIMENSION (<i>ldc</i> , <i>n</i>) and (<i>ldf</i> , <i>n</i>), respectively. On entry, <i>c</i> contains the right-hand-side of the first matrix equation in (1), and <i>f</i> contains the right-hand-side of the second matrix equation in (1).
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . $ldc \geq \max(1, m)$.
<i>d</i> , <i>e</i>	REAL for stgsy2 DOUBLE PRECISION for dtgsy2 COMPLEX for ctgsy2 COMPLEX*16 for ztgsy2. Arrays, DIMENSION (<i>ldd</i> , <i>m</i>) and (<i>lde</i> , <i>n</i>), respectively. On entry, <i>d</i> contains an upper triangular matrix <i>D</i> , and <i>e</i> contains an upper triangular matrix <i>E</i> .
<i>ldd</i>	INTEGER. The leading dimension of the array <i>d</i> . $ldd \geq \max(1, m)$.

<i>lde</i>	INTEGER. The leading dimension of the array <i>e</i> . $lde \geq \max(1, n)$.
<i>ldf</i>	INTEGER. The leading dimension of the array <i>f</i> . $ldf \geq \max(1, m)$.
<i>rdsum</i>	REAL for <i>stgsy2/ctgsy2</i> DOUBLE PRECISION for <i>dtgsy2/ztgsy2</i> . On entry, the sum of squares of computed contributions to the Dif-estimate under computation by ?tgsyL, where the scaling factor <i>rdscal</i> has been factored out.
<i>rdscal</i>	REAL for <i>stgsy2/ctgsy2</i> DOUBLE PRECISION for <i>dtgsy2/ztgsy2</i> . On entry, scaling factor used to prevent overflow in <i>rdsum</i> .
<i>iwork</i>	INTEGER. Used with real flavors only. Workspace array, DIMENSION ($m+n+2$).

Output Parameters

<i>c</i>	On exit, if <i>ijob</i> = 0, <i>c</i> is overwritten by the solution <i>R</i> .
<i>f</i>	On exit, if <i>ijob</i> = 0, <i>f</i> is overwritten by the solution <i>L</i> .
<i>scale</i>	REAL for <i>stgsy2/ctgsy2</i> DOUBLE PRECISION for <i>dtgsy2/ztgsy2</i> . On exit, $0 \leq scale \leq 1$. If $0 < scale < 1$, the solutions <i>R</i> and <i>L</i> (<i>C</i> and <i>F</i> on entry) hold the solutions to a slightly perturbed system, but the input matrices <i>A</i> , <i>B</i> , <i>D</i> and <i>E</i> are not changed. If <i>scale</i> = 0, <i>R</i> and <i>L</i> hold the solutions to the homogeneous system with <i>C</i> = <i>F</i> = 0. Normally <i>scale</i> = 1.
<i>rdsum</i>	On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If <i>trans</i> = 'T', <i>rdsum</i> is not touched. Note that <i>rdsum</i> only makes sense when ?tgsy2 is called by ?tgsyL.
<i>rdscal</i>	On exit, <i>rdscal</i> is updated with respect to the current contributions in <i>rdsum</i> . If <i>trans</i> = 'T', <i>rdscal</i> is not touched.

Note that *rdscal* only makes sense when *?tgsyl* is called by *?tgsyl*.

pq

INTEGER. Used with real flavors only.

On exit, the number of subsystems (of size 2-by-2, 4-by-4 and 8-by-8) solved by the routine *stgsy2/dtgsy2*.

info

INTEGER. On exit, if *info* is set to

= 0: Successful exit

< 0: If *info* = -*i*, the *i*-th argument has an illegal value.

> 0: The matrix pairs (*A*, *D*) and (*B*, *E*) have common or very close eigenvalues.

?trti2

Computes the inverse of a triangular matrix (unblocked algorithm).

Syntax

```
call strti2( uplo, diag, n, a, lda, info )
call dtrti2( uplo, diag, n, a, lda, info )
call ctrti2( uplo, diag, n, a, lda, info )
call ztrti2( uplo, diag, n, a, lda, info )
```

Description

This routine is declared in *mkl_lapack.fi* for FORTRAN 77 interface and in *mkl_lapack.h* for C interface.

The routine *?trti2* computes the inverse of a real/complex upper or lower triangular matrix.

This is the *Level 2 BLAS* version of the algorithm.

Input Parameters

uplo

CHARACTER*1.

Specifies whether the matrix *A* is upper or lower triangular.

= 'U': upper triangular

= 'L': lower triangular

diag

CHARACTER*1.

Specifies whether or not the matrix *A* is unit triangular.

= 'N': non-unit triangular
 = 'N': non-unit triangular

n INTEGER. The order of the matrix *A*. $n \geq 0$.
a REAL for `strti2`
 DOUBLE PRECISION for `dtrti2`
 COMPLEX for `ctrti2`
 COMPLEX*16 for `ztrti2`.
 Array, DIMENSION (*lda*, *n*).
 On entry, the triangular matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of
 the array *a* contains the upper triangular matrix, and the
 strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of
 the array *a* contains the lower triangular matrix, and the
 strictly upper triangular part of *a* is not referenced.
 If *diag* = 'U', the diagonal elements of *a* are also not
 referenced and are assumed to be 1.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, the (triangular) inverse of the original matrix, in
 the same storage format.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*k*, the *k*-th argument had an illegal value

clag2z

Converts a complex single precision matrix to a complex double precision matrix.

Syntax

call `clag2z(m, n, sa, ldsa, a, lda, info)`

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine converts a complex single precision matrix *SA* to a complex double precision matrix *A*.

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $ldsa \geq \max(1, m)$.
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsa</i> , <i>n</i>). On exit, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

dlag2s

Converts a double precision matrix to a single precision matrix.

Syntax

```
call dlag2s( m, n, a, lda, sa, ldsa, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine converts a double precision matrix *SA* to a single precision matrix *A*.

RMAX is the overflow for the single precision arithmetic. `dlag2s` checks that all the entries of *A* are between $-RMAX$ and $RMAX$. If not, the conversion is aborted and a flag is raised.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.
<i>ldsA</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $ldsA \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsA</i> , <i>n</i>). On exit, if <i>info</i> = 0, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>k</i> , the (<i>i</i> , <i>j</i>) entry of the matrix <i>A</i> has overflowed when moving from double precision to single precision. <i>k</i> is given by $k = (i-1)*lda+j$.

slag2d

Converts a single precision matrix to a double precision matrix.

Syntax

```
call slag2d( m, n, sa, ldsa, a, lda, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine converts a single precision matrix *sa* to a double precision matrix *a*.

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $ldsa \geq \max(1, m)$.
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsa</i> , <i>n</i>). On exit, if <i>info</i> = 0, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

zlag2c

Converts a complex double precision matrix to a complex single precision matrix.

Syntax

```
call zlag2c( m, n, a, lda, sa, ldsa, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine converts a double precision complex matrix *SA* to a single precision complex matrix *A*.

RMAX is the overflow for the single precision arithmetic. `zlag2c` checks that all the entries of *A* are between $-RMAX$ and $RMAX$. If not, the conversion is aborted and a flag is raised.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.
<i>lds</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $lds \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>lds</i> , <i>n</i>). On exit, if <i>info</i> = 0, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = k$, the (i, j) entry of the matrix A has overflowed when moving from double precision to single precision. k is given by $k = (i-1)*lda+j$.

Utility Functions and Routines

This section describes LAPACK utility functions and routines. Summary information about these routines is given in the following table:

Table 5-2 LAPACK Utility Routines

Routine Name	Data Types	Description
<code>ilaver</code>		Returns the version of the Lapack library.
<code>ilaenv</code>		Environmental enquiry function which returns values for tuning algorithmic performance.
<code>iparmq</code>		Environmental enquiry function which returns values for tuning algorithmic performance.
<code>ieeeck</code>		Checks if the infinity and NaN arithmetic is safe. Called by <code>ilaenv</code> .
<code>lsame</code>		Tests two characters for equality regardless of case.
<code>lsamen</code>		Tests two character strings for equality regardless of case.
<code>?labad</code>	s, d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
<code>?lamch</code>	s, d	Determines machine parameters for floating-point arithmetic.
<code>?lamc1</code>	s, d	Called from <code>?lamc2</code> . Determines machine parameters given by β , t , rnd , $ieee1$.
<code>?lamc2</code>	s, d	Used by <code>?lamch</code> . Determines machine parameters specified in its arguments list.
<code>?lamc3</code>	s, d	Called from <code>?lamc1</code> - <code>?lamc5</code> . Intended to force a and b to be stored prior to doing the addition of a and b .

Routine Name	Data Types	Description
<code>?lamc4</code>	<code>s, d</code>	This is a service routine for <code>?lamc2</code> .
<code>?lamc5</code>	<code>s, d</code>	Called from <code>?lamc2</code> . Attempts to compute the largest machine floating-point number, without overflow.
<code>second/dsecnd</code>		Return user time for a process.
<code>xerbla</code>		Error handling routine called by LAPACK routines.

ilaver

Returns the version of the Lapack library.

Syntax

```
call ilaver( vers_major, vers_minor, vers_patch )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine returns the version of the LAPACK library.

Output Parameters

<code>vers_major</code>	INTEGER. Returns the major version of the LAPACK library.
<code>vers_minor</code>	INTEGER. Returns the minor version from the major version of the LAPACK library.
<code>vers_patch</code>	INTEGER. Returns the patch version from the minor version of the LAPACK library.

ilaenv

Environmental enquiry function that returns values for tuning algorithmic performance.

Syntax

```
value = ilaenv( ispec, name, opts, n1, n2, n3, n4 )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The enquiry function `ilaenv` is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See *ispec* below for a description of the parameters.

This version provides a set of parameters that should give good, but not optimal, performance on many of the currently available computers. Users are encouraged to modify this subroutine to set the tuning parameters for their particular machine using the option and problem size information in the arguments.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

Input Parameters

<i>ispec</i>	<p>INTEGER.</p> <p>Specifies the parameter to be returned as the value of <code>ilaenv</code>:</p> <ul style="list-style-type: none"> = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance. = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used. = 3: the crossover point (in a block routine, for n less than this value, an unblocked routine should be used) = 4: the number of shifts, used in the nonsymmetric eigenvalue routines (deprecated) = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k-by-m, where k is given by <code>ilaenv(2, ...)</code> and m by <code>ilaenv(5, ...)</code>
--------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	= 6: the crossover point for the SVD (when reducing an m -by- n matrix to bidiagonal form, if $\max(m, n) / \min(m, n)$ exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form.) = 7: the number of processors = 8: the crossover point for the multishift QR and QZ methods for nonsymmetric eigenvalue problems (deprecated). = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by <code>?gelsd</code> and <code>?gesdd</code>) =10: ieee NaN arithmetic can be trusted not to trap =11: infinity arithmetic can be trusted not to trap $12 \leq ispec \leq 16$: <code>?hseqr</code> or one of its subroutines, see <code>iparmq</code> for detailed explanation.
<i>name</i>	CHARACTER*(*). The name of the calling subroutine, in either upper case or lower case.
<i>opts</i>	CHARACTER*(*). The character options to the subroutine <i>name</i> , concatenated into a single character string. For example, <i>uplo</i> = 'U', <i>trans</i> = 'T', and <i>diag</i> = 'N' for a triangular routine would be specified as <i>opts</i> = 'UTN'.
<i>n1, n2, n3, n4</i>	INTEGER. Problem dimensions for the subroutine <i>name</i> ; these may not all be required.

Output Parameters

<i>value</i>	INTEGER. If <i>value</i> ≥ 0 : the value of the parameter specified by <i>ispec</i> ; If <i>value</i> = $-k < 0$: the k -th argument had an illegal value.
--------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.

2. The problem dimensions $n1$, $n2$, $n3$, $n4$ are specified in the order that they appear in the argument list for *name*. $n1$ is used first, $n2$ second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by *ilaenv* is checked for validity in the calling subroutine. For example, *ilaenv* is used to retrieve the optimal blocksize for *strtri* as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1> )
if( nb.le.1 ) nb = max( 1, n )
```

Below is an example of *ilaenv* usage in C language:

```
#include <stdio.h>
#include "mkl.h"
int main(void)
{
    int size = 1000;
    int ispec = 1;
    int dummy = -1;
    int blockSize1 = ilaenv(&ispec, "dsytrd", "U", &size, &dummy, &dummy, &dummy);
    int blockSize2 = ilaenv(&ispec, "dormtr", "LUN", &size, &size, &dummy, &dummy);
    printf("DSYTRD blocksize = %d\n", blockSize1);
    printf("DORMTR blocksize = %d\n", blockSize2);
    return 0;
}
```

- [iparmq](#)

iparmq

Environmental enquiry function which returns values for tuning algorithmic performance.

Syntax

```
value = iparmq( ispec, name, opts, n, ilo, ihi, lwork )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function sets problem and machine dependent parameters useful for `?hseqr` and its subroutines. It is called whenever `ilaenv` is called with $12 \leq ispec \leq 16$.

Input Parameters

ispec INTEGER.
Specifies the parameter to be returned as the value of `iparmq`:

- = 12: (*inmin*) Matrices of order *nmin* or less are sent directly to `?lahqr`, the implicit double shift QR algorithm. *nmin* must be at least 11.
- = 13: (*inwin*) Size of the deflation window. This is best set greater than or equal to the number of simultaneous shifts *ns*. Larger matrices benefit from larger deflation windows.
- = 14: (*inibl*) Determines when to stop nibbling and invest in an (expensive) multi-shift QR sweep. If the aggressive early deflation subroutine finds *ld* converged eigenvalues from an order *nw* deflation window and $ld > (nw * nibble) / 100$, then the next QR sweep is skipped and early deflation is applied immediately to the remaining active diagonal block. Setting `iparmq(ispec=14)=0` causes `TTQRE` to skip a multi-shift QR sweep whenever early deflation finds a converged eigenvalue. Setting `iparmq(ispec=14)` greater than or equal to 100 prevents `TTQRE` from skipping a multi-shift QR sweep.
- = 15: (*nshifts*) The number of simultaneous shifts in a multi-shift QR iteration.

= 16: (*iacc22*) *iparmq* is set to 0, 1 or 2 with the following meanings.

0: During the multi-shift QR sweep, *?laqr5* does not accumulate reflections and does not use matrix-matrix multiply to update the far-from-diagonal matrix entries.

1: During the multi-shift QR sweep, *?laqr5* and/or *?laqr3* accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.

2: During the multi-shift QR sweep, *?laqr5* accumulates reflections and takes advantage of 2-by-2 block structure during matrix-matrix multiplies.

(If *?trrm* is slower than *?gemm*, then *iparmq(ispec=16)=1* may be more efficient than *iparmq(ispec=16)=2* despite the greater level of arithmetic work implied by the latter choice.)

<i>name</i>	CHARACTER*(*) . The name of the calling subroutine.
<i>opts</i>	CHARACTER*(*) . This is a concatenation of the string arguments to TTQRE.
<i>n</i>	INTEGER. <i>n</i> is the order of the Hessenberg matrix <i>H</i> .
<i>ilo, ihi</i>	INTEGER. It is assumed that <i>H</i> is already upper triangular in rows and columns 1: <i>ilo</i> -1 and <i>ihi</i> +1: <i>n</i> .
<i>lwork</i>	INTEGER. The amount of workspace available.

Output Parameters

<i>value</i>	INTEGER. If <i>value</i> ≥ 0: the value of the parameter specified by <i>iparmq</i> ; If <i>value</i> = -k < 0: the k-th argument had an illegal value.
--------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------

Application Notes

The following conventions have been used when calling *ilaenv* from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.

2. The problem dimensions $n1$, $n2$, $n3$, $n4$ are specified in the order that they appear in the argument list for *name*. $n1$ is used first, $n2$ second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by *ilaenv* is checked for validity in the calling subroutine. For example, *ilaenv* is used to retrieve the optimal blocksize for *strtri* as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1 )
if( nb.le.1 ) nb = max( 1, n )
```

ieeeck

*Checks if the infinity and NaN arithmetic is safe.
Called by* *ilaenv*.

Syntax

```
ival = ieeck( ispec, zero, one )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function *ieeeck* is called from *ilaenv* to verify that infinity and possibly NaN arithmetic is safe, that is, will not trap.

Input Parameters

<i>ispec</i>	<p>INTEGER.</p> <p>Specifies whether to test just for infinity arithmetic or both for infinity and NaN arithmetic:</p> <p>If <i>ispec</i> = 0: Verify infinity arithmetic only.</p> <p>If <i>ispec</i> = 1: Verify infinity and NaN arithmetic.</p>
<i>zero</i>	<p>REAL. Must contain the value 0.0</p> <p>This is passed to prevent the compiler from optimizing away this code.</p>
<i>one</i>	<p>REAL. Must contain the value 1.0</p> <p>This is passed to prevent the compiler from optimizing away this code.</p>

Output Parameters

ival INTEGER.
 If *ival* = 0: Arithmetic failed to produce the correct answers.
 If *ival* = 1: Arithmetic produced the correct answers.

lsamen

Tests two character strings for equality regardless of case.

Syntax

val = lsamen(*n*, *ca*, *cb*)

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

This logical function tests if the first *n* letters of the string *ca* are the same as the first *n* letters of *cb*, regardless of case. The function `lsamen` returns `.TRUE.` if *ca* and *cb* are equivalent except for case and `.FALSE.` otherwise. `lsamen` also returns `.FALSE.` if `len(ca)` or `len(cb)` is less than *n*.

Input Parameters

n INTEGER. The number of characters in *ca* and *cb* to be compared.
ca, cb CHARACTER*(*). Specify two character strings of length at least *n* to be compared. Only the first *n* characters of each string will be accessed.

Output Parameters

val LOGICAL. Result of the comparison.

?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call slabad( small, large )
```

```
call dlabad( small, large )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine takes as input the values computed by `slamch/dlamch` for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `?lamch`. This subroutine is needed because `?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

Input Parameters

<i>small</i>	REAL for slabad DOUBLE PRECISION for dlabad. The underflow threshold as computed by <code>?lamch</code> .
<i>large</i>	REAL for slabad DOUBLE PRECISION for dlabad. The overflow threshold as computed by <code>?lamch</code> .

Output Parameters

<i>small</i>	On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>small</i> , otherwise unchanged.
<i>large</i>	On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>large</i> , otherwise unchanged.

?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
val = slamch( cmach )
```

```
val = dlamch( cmach )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The function `?lamch` determines single precision and double precision machine parameters.

Input Parameters

cmach CHARACTER*1. Specifies the value to be returned by `?lamch`:

- = 'E' or 'e', *val* = *eps*
- = 'S' or 's', *val* = *sfmin*
- = 'B' or 'b', *val* = *base*
- = 'P' or 'p', *val* = *eps*base*
- = 'n' or 'n', *val* = *t*
- = 'R' or 'r', *val* = *rnd*
- = 'm' or 'm', *val* = *emin*
- = 'U' or 'u', *val* = *rmin*
- = 'L' or 'l', *val* = *emax*
- = 'O' or 'o', *val* = *rmax*

where

- eps* = relative machine precision;
- sfmin* = safe minimum, such that $1/sfmin$ does not overflow;
- base* = base of the machine;
- prec* = *eps*base*;
- t* = number of (base) digits in the mantissa;
- rnd* = 1.0 when rounding occurs in addition, 0.0 otherwise;
- emin* = minimum exponent before (gradual) underflow;
- rmin* = $underflow_threshold - base^{*(emin-1)}$;

$emax$ = largest exponent before overflow;
 $rmax = overflow_threshold - (base**emax)*(1-eps)$.

Output Parameters

val REAL for slamch
 DOUBLE PRECISION for dlamch
 Value returned by the function.

?lamc1

Called from ?lamc2. Determines machine parameters given by β , t , rnd , $ieee1$.

Syntax

call slamc1(β , t , rnd , $ieee1$)
 call dlamc1(β , t , rnd , $ieee1$)

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lamc1 determines machine parameters given by β , t , rnd , $ieee1$.

Output Parameters

β INTEGER. The base of the machine.
 t INTEGER. The number of (β) digits in the mantissa.
 rnd LOGICAL.
 Specifies whether proper rounding ($rnd = .TRUE.$) or chopping ($rnd = .FALSE.$) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.
 $ieee1$ LOGICAL.
 Specifies whether rounding appears to be done in the *ieee* 'round to nearest' style.

?lamc2

Used by ?lamch. Determines machine parameters specified in its arguments list.

Syntax

```
call slamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
```

```
call dlamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine ?lamc2 determines machine parameters specified in its arguments list.

Output Parameters

<i>beta</i>	INTEGER. The base of the machine.
<i>t</i>	INTEGER. The number of (<i>beta</i>) digits in the mantissa.
<i>rnd</i>	LOGICAL. Specifies whether proper rounding (<i>rnd</i> = .TRUE.) or chopping (<i>rnd</i> = .FALSE.) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.
<i>eps</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest positive number such that $fl(1.0 - eps) < 1.0$, where <i>fl</i> denotes the computed value.
<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow occurs.
<i>rmin</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest normalized number for the machine, given by $base^{emin-1}$, where <i>base</i> is the floating point value of <i>beta</i> .
<i>emax</i>	INTEGER. The maximum exponent before overflow occurs.

rmax REAL for slamc2
 DOUBLE PRECISION for dlamc2
 The largest positive number for the machine, given by $base^{emax(1 - eps)}$, where *base* is the floating point value of *beta*.

?lamc3

*Called from ?lamc1-?lamc5. Intended to force *a* and *b* to be stored prior to doing the addition of *a* and *b*.*

Syntax

```
val = slamc3( a, b )
val = dlamc3( a, b )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine is intended to force *A* and *B* to be stored prior to doing the addition of *A* and *B*, for use in situations where optimizers might hold one of these in a register.

Input Parameters

a, b REAL for slamc3
 DOUBLE PRECISION for dlamc3
 The values *a* and *b*.

Output Parameters

val REAL for slamc3
 DOUBLE PRECISION for dlamc3
 The result of adding values *a* and *b*.

?lamc4

This is a service routine for ?lamc2.

Syntax

```
call slamc4( emin, start, base )
call dlamc4( emin, start, base )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

This is a service routine for [?lamc2](#).

Input Parameters

<i>start</i>	REAL for <code>slamc4</code> DOUBLE PRECISION for <code>dlamc4</code> The starting point for determining <i>emin</i> .
<i>base</i>	INTEGER. The base of the machine.

Output Parameters

<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow, computed by setting <i>a</i> = <i>start</i> and dividing by <i>base</i> until the previous <i>a</i> can not be recovered.
-------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

?lamc5

Called from ?lamc2. Attempts to compute the largest machine floating-point number, without overflow.

Syntax

```
call slamc5( beta, p, emin, ieee, emax, rmax)
call dlamc5( beta, p, emin, ieee, emax, rmax)
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine `?lamc5` attempts to compute r_{max} , the largest machine floating-point number, without overflow. It assumes that $e_{max} + \text{abs}(e_{min})$ sum approximately to a power of 2. It will fail on machines where this assumption does not hold, for example, the Cyber 205 ($e_{min} = -28625$, $e_{max} = 28718$). It will also fail if the value supplied for e_{min} is too large (that is, too close to zero), probably with overflow.

Input Parameters

<i>beta</i>	INTEGER. The base of floating-point arithmetic.
<i>p</i>	INTEGER. The number of base <i>beta</i> digits in the mantissa of a floating-point value.
<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow.
<i>ieee</i>	LOGICAL. A logical flag specifying whether or not the arithmetic system is thought to comply with the IEEE standard.

Output Parameters

<i>emax</i>	INTEGER. The largest exponent before overflow.
<i>rmax</i>	REAL for <code>slamc5</code> DOUBLE PRECISION for <code>dlamc5</code> The largest machine floating-point number.

second/dsecnd

Return user time for a process.

Syntax

`val = second()`

`val = dsecnd()`

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The functions `second/dsecnd` return the user time for a process in seconds. These versions get the time from the system function `etime`. The difference is that `dsecnd` returns the result with double precision.

Output Parameters

<code>val</code>	REAL for <code>second</code> DOUBLE PRECISION for <code>dsecnd</code> User time for a process.
------------------	------------------------------------------------------------------------------------------------------

Progress Routine

The *Progress Routine* is a callback `mkl_progress` function intended to track progress of a lengthy computation and/or interrupt the computation. This function is regularly called from a set of LAPACK routines that support the progress feature. By default, the progress routine does nothing, but the user application can redefine it to perform some operations during the LAPACK routine computation, for instance, to print a progress indicator.

mkl_progress

Provides progress information.

Syntax

```
stopflag = mkl_progress( thread, step, stage )
```

Description

This function is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The progress routine `mkl_progress` is regularly called from some LAPACK routines during the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. A non-zero return value may be supplied by the redefined function to break the computation.

Input Parameters

<i>thread</i>	INTEGER*4. The number of the thread the progress routine is called from. 0 is passed for sequential code.
<i>step</i>	INTEGER*4. The linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
<i>stage</i>	CHARACTER*(*). The name of the LAPACK routine, which the progress routine is called from.

Output Parameters

<i>stopflag</i>	INTEGER. The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.
-----------------	---------------------------------------------------------------------------------------------------------------------------------

Application Notes

Note that `mkl_progress` is a Fortran routine, that is, to redefine the progress routine from C, the name should be spelled differently, parameters should be passed by reference, and an extra parameter meaning the length of the stage string should be considered. The stage string is not terminated with the `NULL` character. The C interface of the progress routine is the following:

```
int mkl_progress( int* thread, int* step, char* stage, int len ); // Linux, Mac
int MKL_PROGRESS( int* thread, int* step, char* stage, int len ); // Windows
```

Below are the examples of printing a progress information on the standard output in Fortran and C languages:

Examples

Fortran:

```
integer function mkl_progress( thread, step, stage )
integer*4 thread, step
character*(*) stage
print*, 'Thread:', thread, ', stage:', stage, ', step:', step
mkl_progress = 0
return
end
```

C:

```
#include <string.h>
#define BUFLen 16
int mkl_progress_( int* ithr, int* step, char* stage, int len ){
    char buf[BUFLen];
    if( len >= BUFLen ) len = BUFLen-1;
    strncpy( buf, stage, len );
    buf[len] = '\0';
    printf( 'In thread %i, at stage %s, steps passed %i\n', *ithr,
buf, *step );
    return 0;
}
```

ScaLAPACK Routines

This chapter describes the Intel® Math Kernel Library implementation of routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Intel MKL ScaLAPACK routines are written in FORTRAN 77 with exception of a few utility routines written in C to exploit the IEEE arithmetic. All routines are available in all precision types: single precision, double precision, complex and double complex precision. C declarations of ScaLAPACK routines can be found in the `mk1_scalapack.h` header file.

NOTE. ScaLAPACK routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Sections in this chapter include descriptions of ScaLAPACK [computational routines](#) that perform distinct computational tasks, as well as [driver routines](#) for solving standard types of problems in one call.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel MKL version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements, see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on ScaLAPACK routines and related information, see [\[SLUG\]](#).

Overview

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. An example of an array descriptor structure is given in [Table 6-1](#).

Table 6-1 Content of the array descriptor for dense matrices

Array Element #	Name	Definition
1	<i>dtype</i>	Descriptor type (=1 for dense matrices)
2	<i>ctxt</i>	BLACS context handle for the process grid
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>lld</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by $LOC_r()$ and $LOC_c()$, respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix A , which is contained in the global subarray $sub(A)$, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of $sub(A)$
<i>n</i>	The number of columns of $sub(A)$
<i>a</i>	A pointer to the local array containing the entire global array A
<i>ia</i>	The row index of $sub(A)$ in the global array
<i>ja</i>	The column index of $sub(A)$ in the global array
<i>desca</i>	The array descriptor for the global array

Routine Naming Conventions

For each routine introduced in this chapter, you can use the ScaLAPACK name. The naming convention for ScaLAPACK routines is similar to that used for LAPACK routines (see [Routine Naming Conventions in Chapter 4](#)). A general rule is that each routine name in ScaLAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter `p`.

ScaLAPACK names have the structure `p?yyzzz` or `p?yyzz`, which is described below.

The initial letter `p` is a distinctive prefix of ScaLAPACK routines and is present in each such routine.

The second symbol `?` indicates the data type:

s	real, single precision
d	real, double precision
c	complex, single precision
z	complex, double precision

The second and third letters *yy* indicate the matrix type as:

ge	general
gb	general band
gg	a pair of general matrices (for a generalized problem)
dt	general tridiagonal (diagonally dominant-like)
db	general band (diagonally dominant-like)
po	symmetric or Hermitian positive-definite
pb	symmetric or Hermitian positive-definite band
pt	symmetric or Hermitian positive-definite tridiagonal
sy	symmetric
st	symmetric tridiagonal (real)
he	Hermitian
or	orthogonal
tr	triangular (or quasi-triangular)
tz	trapezoidal
un	unitary

For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

sv	a <i>simple</i> driver for solving a linear system
svx	an <i>expert</i> driver for solving a linear system
ls	a driver for solving a linear least squares problem
ev	a simple driver for solving a symmetric eigenvalue problem
evx	an expert driver for solving a symmetric eigenvalue problem
svd	a driver for computing a singular value decomposition
gvx	an expert driver for solving a generalized symmetric definite eigenvalue problem

Simple driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

Computational Routines

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- [Solving Systems of Linear Equations](#)
- [Orthogonal Factorizations and LLS Problems](#)
- [Symmetric Eigenproblems](#)
- [Nonsymmetric Eigenproblems](#)
- [Singular Value Decomposition](#)
- [Generalized Symmetric-Definite Eigenproblems](#)

See also the respective [driver routines](#).

Linear Equations

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded
- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the *LU* factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See [Table 6-2](#) for full list of available routines.

To solve a particular problem, you can either call two or more computational routines or call a corresponding [driver routine](#) that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf` (*LU* factorization) and then `p?getrs` (computing the solution). Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

[Table 6-2](#) lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

Table 6-2 Computational Routines for Systems of Linear Equations

Matrix type, storage scheme	Factorize matrix	Equilibrate matrix	Solve system	Condition number	Estimate error	Invert matrix
general (partial pivoting)	<code>p?getrf</code>	<code>p?geequ</code>	<code>p?getrs</code>	<code>p?gecon</code>	<code>p?gerfs</code>	<code>p?getri</code>
general band (partial pivoting)	<code>p?gbtrf</code>		<code>p?gbtrs</code>			
general band (no pivoting)	<code>p?dbtrf</code>		<code>p?dbtrs</code>			
general tridiagonal (no pivoting)	<code>p?dttrf</code>		<code>p?dttrs</code>			
symmetric/Hermitian positive-definite	<code>p?potrf</code>	<code>p?poequ</code>	<code>p?potrs</code>	<code>p?pocon</code>	<code>p?porfs</code>	<code>p?potri</code>
symmetric/Hermitian positive-definite, band	<code>p?pbtrf</code>		<code>p?pbtrs</code>			
symmetric/Hermitian positive-definite, tridiagonal	<code>p?pttrf</code>		<code>p?pttrs</code>			
triangular			<code>p?trtrs</code>	<code>p?trcon</code>	<code>p?trrfs</code>	<code>p?trtri</code>

In this table `?` stands for `s` (single precision real), `d` (double precision real), `c` (single precision complex), or `z` (double precision complex).

Routines for Matrix Factorization

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

p?getrf

Computes the LU factorization of a general m -by- n distributed matrix.

Syntax

```
call psgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pdgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pcgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pzgetrf(m, n, a, ia, ja, desca, ipiv, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine forms the LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ as

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). L and U are stored in $\text{sub}(A)$.

The routine uses partial pivoting, with row interchanges.

Input Parameters

m	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; $m \geq 0$.
n	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; $n \geq 0$.
a	(local) REAL for psgetrf DOUBLE PRECISION for pdgetrf COMPLEX for pcgetrf DOUBLE COMPLEX for pzgetrf.

	<p>Pointer into the local memory to an array of local dimension $(lld_a, LOCc(ja+n-1))$. Contains the local pieces of the distributed matrix sub(A) to be factored.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A.</p>

Output Parameters

<i>a</i>	<p>Overwritten by local pieces of the factors L and U from the factorization $A = P*L*U$. The unit diagonal elements of L are not stored.</p>
<i>ipiv</i>	<p>(local) INTEGER array. The dimension of <i>ipiv</i> is $(LOCr(m_a) + mb_a)$. This array contains the pivoting information: local row i was interchanged with global row $ipiv(i)$. This array is tied to the distributed matrix A.</p>
<i>info</i>	<p>(global) INTEGER. If <i>info</i>=0, the execution is successful. <i>info</i> < 0: if the i-th argument is an array and the j-th entry had an illegal value, then $info = -(i*100+j)$; if the i-th argument is a scalar and had an illegal value, then $info = -i$. If $info = i, u_{ii}$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.</p>

p?gbtrf

Computes the LU factorization of a general n -by- n banded distributed matrix.

Syntax

```
call psgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pdgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pcgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pzgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine computes the LU factorization of a general n -by- n real/complex banded distributed matrix $A(1:n, ja:ja+n-1)$ using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK routine [?gbtrf](#). Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

$$A(1:n, ja:ja+n-1) = P * L * U * Q$$

where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
<i>bwl</i>	(global) INTEGER. The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).

<i>a</i>	<p>(local)</p> <p>REAL for psgbtrf DOUBLE PRECISION for pdgbtrf COMPLEX for pcgbtrf DOUBLE COMPLEX for pzgbtrf.</p> <p>Pointer into the local memory to an array of local dimension (<i>lld_a</i>, <i>LOC_c</i>(<i>ja</i>+<i>n</i>-1) where</p> $lld_a \geq 2*bw1 + 2*bwu + 1.$ <p>Contains the local pieces of the <i>n</i>-by-<i>n</i> distributed banded matrix <i>A</i>(1:<i>n</i>, <i>ja</i>:<i>ja</i>+<i>n</i>-1) to be factored.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p> <p>If <i>desca</i>(<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i>(<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.</p>
<i>laf</i>	<p>(local) INTEGER. The dimension of the array <i>af</i>.</p> <p>Must be <i>laf</i> ≥</p> $(NB+bwu) * (bw1+bwu) + 6 * (bw1+bwu) * (bw1+2*bwu).$ <p>If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).</p>
<i>work</i>	<p>(local) Same type as <i>a</i>. Workspace array of dimension <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER. The size of the <i>work</i> array (<i>lwork</i> ≥ 1) . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i>(1) and an error code is returned.</p>

Output Parameters

<i>a</i>	<p>On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.</p>
<i>ipiv</i>	<p>(local) INTEGER array.</p>

	<p>The dimension of <i>ipiv</i> must be $\geq \text{desca}(\text{NB})$.</p> <p>Contains pivot indices for local factorizations. Note that you <i>should not alter</i> the contents of this array between factorization and solve.</p>
<i>af</i>	<p>(local)</p> <p>REAL for psgbtrf DOUBLE PRECISION for pdgbtrf COMPLEX for pcgbtrf DOUBLE COMPLEX for pzgbtrf.</p> <p>Array, dimension (<i>laf</i>).</p> <p>Auxiliary Fillin space. Fillin is created during the factorization routine p?gbtrf and this is stored in <i>af</i>.</p> <p>Note that if a linear system is to be solved using p?gbtrs after the factorization routine, <i>af</i> must not be altered after the factorization.</p>
<i>work</i> (1)	<p>On exit, <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance.</p>
<i>info</i>	<p>(global) INTEGER.</p> <p>If <i>info</i>=0, the execution is successful.</p> <p><i>info</i> < 0:</p> <p>If the <i>i</i>th argument is an array and the <i>j</i>th entry had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.</p> <p><i>info</i> > 0:</p> <p>If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not nonsingular, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i>-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.</p>

p?dbtrf

Computes the LU factorization of a n -by- n diagonally dominant-like banded distributed matrix.

Syntax

```
call psdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pddbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pcdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pzdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the LU factorization of a n -by- n real/complex diagonally dominant-like banded distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

Input Parameters

n	(global) INTEGER. The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
bwl	(global) INTEGER. The number of sub-diagonals within the band of A $(0 \leq bwl \leq n-1)$.
bwu	(global) INTEGER. The number of super-diagonals within the band of A $(0 \leq bwu \leq n-1)$.
a	(local) REAL for psdbtrf DOUBLE PRECISION for pddbtrf COMPLEX for pcdbtrf DOUBLE COMPLEX for pzdbtrf. Pointer into the local memory to an array of local dimension $(lld_a, LOCC(ja+n-1))$.

	Contains the local pieces of the n -by- n distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>a</i> or a submatrix of <i>a</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>a</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + (\max(bwl, bwu))^2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be $lwork \geq (\max(bwl, bwu))^2$. If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned.

Output Parameters

<i>a</i>	On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>af</i>	(local) REAL for psdbtrf DOUBLE PRECISION for pddbtrf COMPLEX for pcdbtrf DOUBLE COMPLEX for pzdbtrf. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?dbtrf and this is stored in <i>af</i> .

Note that if a linear system is to be solved using `p?dbtrs` after the factorization routine, `af` must not be altered after the factorization.

`work(1)` On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info` (global) INTEGER.
 If `info=0`, the execution is successful.
`info < 0`:
 If the `i`th argument is an array and the `j`-th entry had an illegal value, then `info = -(i*100+j)`; if the `i`-th argument is a scalar and had an illegal value, then `info = -i`. `info > 0`:
 If `info = k ≤ NPROCS`, the submatrix stored on processor `info` and factored locally was not diagonally dominant-like, and the factorization was not completed. If `info = k > NPROCS`, the submatrix stored on processor `info-NPROCS` representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.

Syntax

```
call pspotrf(uplo, n, a, ia, ja, desca, info)
call pdpotrf(uplo, n, a, ia, ja, desca, info)
call pcpotrf(uplo, n, a, ia, ja, desca, info)
call pzpotrf(uplo, n, a, ia, ja, desca, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed n -by- n matrix $A(ia:ia+n-1, ja:ja+n-1)$, denoted below as $\text{sub}(A)$.

The factorization has the form

$\text{sub}(A) = U^H * U$ if $\text{uplo} = 'U'$, or

$\text{sub}(A) = L * L^H$ if $\text{uplo} = 'L'$

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored. Must be 'U' or 'L'. If $\text{uplo} = 'U'$, the array <i>a</i> stores the upper triangular part of the matrix $\text{sub}(A)$ that is factored as $U^H * U$. If $\text{uplo} = 'L'$, the array <i>a</i> stores the lower triangular part of the matrix $\text{sub}(A)$ that is factored as $L * L^H$.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pspotrff DOUBLE PRECISION for pdpotrf COMPLEX for pcpotrff DOUBLE COMPLEX for pzpotrff. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$ to be factored. Depending on <i>uplo</i> , the array <i>a</i> contains either the upper or the lower triangular part of the matrix $\text{sub}(A)$ (see <i>uplo</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful; <i>info</i> < 0: if the <i>i</i> -th argument is an array, and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> = <i>k</i> > 0, the leading minor of order <i>k</i> , <i>A</i> (<i>ia:ia+k-1</i> , <i>ja:ja+k-1</i>), is not positive-definite, and the factorization could not be completed.

p?pbtrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite banded distributed matrix.

Syntax

```
call pspbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pdpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pcpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pzpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes the Cholesky factorization of an *n*-by-*n* real symmetric or complex Hermitian positive-definite banded distributed matrix *A*(1:*n*, *ja:ja+n-1*).

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$A(1:n, ja:ja+n-1) = P * U^H * P^T$, if *uplo*='U', or

$A(1:n, ja:ja+n-1) = P * L * L^H * P^T$, if *uplo*='L',

where P is a permutation matrix and U and L are banded upper and lower triangular matrices, respectively.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;</p> <p>If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.</p>
<i>n</i>	<p>(global) INTEGER. The order of the distributed submatrix $A(1:n, ja:ja+n-1)$.</p> <p>($n \geq 0$).</p>
<i>bw</i>	<p>(global) INTEGER.</p> <p>The number of superdiagonals of the distributed matrix if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L'.</p> <p>($bw \geq 0$).</p>
<i>a</i>	<p>(local)</p> <p>REAL for pspbtrf</p> <p>DOUBLE PRECISION for pdpbtrf</p> <p>COMPLEX for pcpbtrf</p> <p>DOUBLE COMPLEX for pzpbtrf.</p> <p>Pointer into the local memory to an array of dimension ($lld_a, LOCC(ja+n-1)$).</p> <p>On entry, this array contains the local pieces of the upper or lower triangle of the symmetric/Hermitian band distributed matrix $A(1:n, ja:ja+n-1)$ to be factored.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A.</p> <p>If $desca(dtype_)$ = 501, then $dlen_ \geq 7$;</p> <p>else if $desca(dtype_)$ = 1, then $dlen_ \geq 9$.</p>
<i>laf</i>	<p>(local) INTEGER. The dimension of the array <i>af</i>.</p> <p>Must be $laf \geq (NB+2*bw)*bw$.</p>

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work (local) Same type as *a*. Workspace array of dimension *lwork*.

lwork (local or global) INTEGER. The size of the *work* array, must be $lwork \geq bw^2$.

Output Parameters

a On exit, if *info*=0, contains the permuted triangular factor *U* or *L* from the Cholesky factorization of the band matrix $A(1:n, ja:ja+n-1)$, as specified by *uplo*.

af (local)
 REAL for pspbtrf
 DOUBLE PRECISION for pdpbtrf
 COMPLEX for pcpbtrf
 DOUBLE COMPLEX for pzpbtrf.
 Array, dimension (*laf*). Auxiliary Fillin space. Fillin is created during the factorization routine *p?pbtrf* and this is stored in *af*. Note that if a linear system is to be solved using *p?pbtrs* after the factorization routine, *af* must not be altered.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 If *info*=0, the execution is successful.
info < 0:
 If the *i*th argument is an array and the *j*th entry had an illegal value, then $info = -(i*100+j)$; if the *i*th argument is a scalar and had an illegal value, then $info = -i$.
info > 0:
 If $info = k \leq NPROCS$, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If $info = k > NPROCS$, the submatrix stored on processor $info - NPROCS$ representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?pttrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite tridiagonal distributed matrix.

Syntax

```
call pspttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pdpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pcpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pzpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes the Cholesky factorization of an n -by- n real symmetric or complex hermitian positive-definite tridiagonal distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P * L * D * L^H * P^T, \text{ or}$$

$$A(1:n, ja:ja+n-1) = P * U^H * D * U * P^T,$$

where P is a permutation matrix, and U and L are tridiagonal upper and lower triangular matrices, respectively.

Input Parameters

n (global) INTEGER. The order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).

<i>d, e</i>	<p>(local)</p> <p>REAL for pspttrf DOUBLE PRECISION for pdpttrf COMPLEX for pcpttrf DOUBLE COMPLEX for pzpttrf.</p> <p>Pointers into the local memory to arrays of dimension $(desca(nb_))$ each.</p> <p>On entry, the array <i>d</i> contains the local part of the global vector storing the main diagonal of the distributed matrix <i>A</i>.</p> <p>On entry, the array <i>e</i> contains the local part of the global vector storing the upper diagonal of the distributed matrix <i>A</i>.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i>.</p> <p>If $desca(dtype_) = 501$, then $dlen_ \geq 7$; else if $desca(dtype_) = 1$, then $dlen_ \geq 9$.</p>
<i>laf</i>	<p>(local) INTEGER. The dimension of the array <i>af</i>.</p> <p>Must be $laf \geq NB+2$.</p> <p>If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).</p>
<i>work</i>	<p>(local) Same type as <i>d</i> and <i>e</i>. Workspace array of dimension <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER. The size of the <i>work</i> array, must be at least</p> <p>$lwork \geq 8 * NPCOL$.</p>

Output Parameters

<i>d, e</i>	On exit, overwritten by the details of the factorization.
<i>af</i>	<p>(local)</p> <p>REAL for pspttrf DOUBLE PRECISION for pdpttrf</p>

COMPLEX for pcpttrf
DOUBLE COMPLEX for pzpttrf.
Array, dimension (*laf*).
Auxiliary Fillin space. Fillin is created during the factorization routine p?pttrf and this is stored in *af*.
Note that if a linear system is to be solved using p?pttrs after the factorization routine, *af* must not be altered.

work(1)
On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info
(global) INTEGER.
If *info*=0, the execution is successful.
info < 0:
If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
info > 0:
If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dttrf

Computes the LU factorization of a diagonally dominant-like tridiagonal distributed matrix.

Syntax

```
call psdttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pddttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pcdttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pzdtttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes the LU factorization of an n -by- n real/complex diagonally dominant-like tridiagonal distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting for stability.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P * L * U * P^T,$$

where P is a permutation matrix, and L and U are banded lower and upper triangular matrices, respectively.

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).
dl, d, du	<p>(local)</p> <p>REAL for <code>pspttrf</code> DOUBLE PRECISION for <code>pdpttrf</code> COMPLEX for <code>pcpttrf</code> DOUBLE COMPLEX for <code>pzpttrf</code>.</p> <p>Pointers to the local arrays of dimension $(desca(nb_))$ each.</p> <p>On entry, the array dl contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, $dl(1)$ is not referenced, and dl must be aligned with d.</p> <p>On entry, the array d contains the local part of the global vector storing the diagonal elements of the matrix.</p> <p>On entry, the array du contains the local part of the global vector storing the super-diagonal elements of the matrix. $du(n)$ is not referenced, and du must be aligned with d.</p>
ja	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be <i>laf</i> ≥ 2*(NB+2) . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>d</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be at least <i>lwork</i> ≥ 8*NPCOL.

Output Parameters

<i>dl, d, du</i>	On exit, overwritten by the information containing the factors of the matrix.
<i>af</i>	(local) REAL for psdtttrf DOUBLE PRECISION for pddtttrf COMPLEX for pcdtttrf DOUBLE COMPLEX for pzdttrf. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?dttrf and this is stored in <i>af</i> . Note that if a linear system is to be solved using p?dttrs after the factorization routine, <i>af</i> must not be altered.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

info > 0:

If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not diagonally dominant-like, and the factorization was not completed. If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

Routines for Solving Systems of Linear Equations

This section describes the ScaLAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

p?getrs

Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by p?getrf.

Syntax

```
call psgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine solves a system of distributed linear equations with a general n -by- n distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the LU factorization computed by `p?getrf`.

The system has one of the following forms specified by *trans*:

$\text{sub}(A) * X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T * X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H * X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1)$.

Before calling this routine, you must call `p?getrf` to compute the *LU* factorization of $\text{sub}(A)$.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for <i>X</i> . If <i>trans</i> = 'T', then $\text{sub}(A)^T * X = \text{sub}(B)$ is solved for <i>X</i> . If <i>trans</i> = 'C', then $\text{sub}(A)^H * X = \text{sub}(B)$ is solved for <i>X</i> .
<i>n</i>	(global) INTEGER. The number of linear equations; the order of the submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(global) REAL for psgetrs DOUBLE PRECISION for pdgetrs COMPLEX for pcgetrs DOUBLE COMPLEX for pzgetrs. Pointers into the local memory to arrays of local dimension $a(lld_a, LOCc(ja+n-1))$ and $b(lld_b, LOCc(jb+nrhs-1))$, respectively. On entry, the array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P * L * U$; the unit diagonal elements of <i>L</i> are not stored. On entry, the array <i>b</i> contains the right hand sides $\text{sub}(B)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>ipiv</i>	(local) INTEGER array.

The dimension of *ipiv* is $(LOCr(m_a) + mb_a)$. This array contains the pivoting information: local row *i* of the matrix was interchanged with the global row *ipiv*(*i*).

This array is tied to the distributed matrix *A*.

ib, jb

(global) INTEGER. The row and column indices in the global array *B* indicating the first row and the first column of the submatrix *sub*(*B*), respectively.

descb

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *B*.

Output Parameters

b

On exit, overwritten by the solution distributed matrix *x*.

info

INTEGER. If *info*=0, the execution is successful. *info* < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

p?gbtrs

Solves a system of distributed linear equations with a general band matrix, using the LU factorization computed by p?gbtrf.

Syntax

```
call psgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
lwf, work, lwork, info)
```

```
call pdgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
lwf, work, lwork, info)
```

```
call pcgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
lwf, work, lwork, info)
```

```
call pzgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
lwf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine solves a system of distributed linear equations with a general band distributed matrix $\text{sub}(A) = A(1:n, ja:ja+n-1)$ using the *LU* factorization computed by `p?gbtrf`.

The system has one of the following forms specified by *trans*:

$\text{sub}(A) * X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T * X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H * X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)$.

Before calling this routine, you must call `p?gbtrf` to compute the *LU* factorization of $\text{sub}(A)$.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for <i>X</i> . If <i>trans</i> = 'T', then $\text{sub}(A)^T * X = \text{sub}(B)$ is solved for <i>X</i> . If <i>trans</i> = 'C', then $\text{sub}(A)^H * X = \text{sub}(B)$ is solved for <i>X</i> .
<i>n</i>	(global) INTEGER. The number of linear equations; the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. The number of sub-diagonals within the band of <i>A</i> ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of super-diagonals within the band of <i>A</i> ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(global) REAL for <code>psgbtrs</code> DOUBLE PRECISION for <code>pdgbtrs</code> COMPLEX for <code>pcgbtrs</code>

	DOUBLE COMPLEX for pzgbtrs. Pointers into the local memory to arrays of local dimension $a(lld_a, LOC_c(ja+n-1))$ and $b(lld_b, LOC_c(nrhs))$, respectively. The array a contains details of the LU factorization of the distributed band matrix A . On entry, the array b contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
ja	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$desca$	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A . If $desca(dtype_)$ = 501, then $dlen_ \geq 7$; else if $desca(dtype_)$ = 1, then $dlen_ \geq 9$.
ib	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$descb$	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A . If $desca(dtype_)$ = 501, then $dlen_ \geq 7$; else if $desca(dtype_)$ = 1, then $dlen_ \geq 9$.
laf	(local) INTEGER. The dimension of the array af . Must be $laf \geq NB*(bwl+bwu)+6*(bwl+bwu)*(bwl+2*bwu)$. If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af(1)$.
$work$	(local) Same type as a . Workspace array of dimension $lwork$.
$lwork$	(local or global) INTEGER. The size of the $work$ array, must be at least $lwork \geq nrhs*(NB+2*bwl+4*bwu)$.

Output Parameters

$ipiv$	(local) INTEGER array. The dimension of $ipiv$ must be $\geq desca(NB)$.
--------	------------------------------------------------------------------------------

	Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve.
<i>b</i>	On exit, overwritten by the local pieces of the solution distributed matrix <i>x</i> .
<i>af</i>	(local) REAL for psgbtrs DOUBLE PRECISION for pdgbtrs COMPLEX for pcgbtrs DOUBLE COMPLEX for pzgbtrs. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?gbtrf and this is stored in <i>af</i> . Note that if a linear system is to be solved using p?gbtrs after the factorization routine, <i>af</i> must not be altered after the factorization.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?potrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian distributed positive-definite matrix.

Syntax

```
call pspotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pcpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pzpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine `p?potrs` solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1)$.

This routine uses Cholesky factorization

$$\text{sub}(A) = U^H * U, \text{ or } \text{sub}(A) = L * L^H$$

computed by `p?potrf`.

Input Parameters

uplo (global) CHARACTER*1. Must be 'U' or 'L'.
If *uplo* = 'U', upper triangle of $\text{sub}(A)$ is stored;
If *uplo* = 'L', lower triangle of $\text{sub}(A)$ is stored.

n (global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

nrhs (global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($\text{nrhs} \geq 0$).

a, b (local)
REAL for `pspotrs`
DOUBLE PRECISION for `pdpotrs`
COMPLEX for `pcpotrs`
DOUBLE COMPLEX for `pzpotrs`.
Pointers into the local memory to arrays of local dimension $a(\text{lld_a}, \text{LOCc}(\text{ja}+n-1))$ and $b(\text{lld_b}, \text{LOCc}(\text{jb}+\text{nrhs}-1))$, respectively.
The array *a* contains the factors L or U from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$, as computed by `p?potrf`.
On entry, the array *b* contains the local pieces of the right hand sides $\text{sub}(B)$.

<i>ia, ja</i>	(global) <code>INTEGER</code> . The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) <code>INTEGER</code> array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) <code>INTEGER</code> . The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix <code>sub(B)</code> , respectively.
<i>descb</i>	(global and local) <code>INTEGER</code> array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	Overwritten by the local pieces of the solution matrix <i>x</i> .
<i>info</i>	<code>INTEGER</code> . If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>) ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?pbtrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian positive-definite band matrix.

Syntax

```
call pspbtrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
             lwork, info)

call pdpbtrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
             lwork, info)

call pcpbtrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
             lwork, info)

call pzpbtrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
             lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine `p?pbtrs` solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed band matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses Cholesky factorization

$$\text{sub}(A) = P * U^H * U * P^T, \text{ or } \text{sub}(A) = P * L * L^H * P^T$$

computed by `p?pbtrf`.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $\text{sub}(A)$ is stored; If <i>uplo</i> = 'L', lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>bw</i>	(global) INTEGER. The number of superdiagonals of the distributed matrix if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L' ($bw \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for <code>pspbtrs</code> DOUBLE PRECISION for <code>pdpbtrs</code> COMPLEX for <code>pcpbtrs</code> DOUBLE COMPLEX for <code>pzpbtrs</code> . Pointers into the local memory to arrays of local dimension $a(lld_a, LOCc(ja+n-1))$ and $b(lld_b, LOCc(nrhs-1))$, respectively.

	<p>The array <i>a</i> contains the permuted triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = P^*U^H*U*P^T$, or $\text{sub}(A) = P^*L^*L^H*P^T$ of the band matrix <i>A</i>, as returned by <code>p?pbtrf</code>.</p> <p>On entry, the array <i>b</i> contains the local pieces of the <i>n</i>-by-<i>nrhs</i> right hand side distributed matrix $\text{sub}(B)$.</p>
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> indicating the first row of the submatrix $\text{sub}(B)$.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb</i> (<i>dtype_</i>) = 502, then <i>dlen_</i> ≥ 7; else if <i>descb</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) Arrays, same type as <i>a</i> . The array <i>af</i> is of dimension (<i>laf</i>). It contains auxiliary Fillin space. Fillin is created during the factorization routine <code>p?dbtrf</code> and this is stored in <i>af</i> . The array <i>work</i> is a workspace array of dimension <i>lwork</i> .
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be <i>laf</i> ≥ <i>nrhs</i> * <i>bw</i> . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> , must be at least <i>lwork</i> ≥ <i>bw</i> ² .

Output Parameters

<i>b</i>	On exit, if <i>info</i> =0, this array contains the local pieces of the <i>n</i> -by- <i>nrhs</i> solution distributed matrix <i>X</i> .
----------	------------------------------------------------------------------------------------------------------------------------------------------

`work(1)` On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info` INTEGER. If `info=0`, the execution is successful.
`info < 0`:
 If the i -th argument is an array and the j -th entry had an illegal value, then `info` = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then `info` = $-i$.

p?pttrs

Solves a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal distributed matrix using the factorization computed by p?pttrf.

Syntax

```
call pspttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork,
info)

call pdpttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork,
info)

call pcpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pzpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine `p?pttrs` solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the factorization

$\text{sub}(A) = P^*L^*D^*L^H*P^T$, or $\text{sub}(A) = P^*U^H*D^*U^*P^T$

computed by `p?pttrf`.

Input Parameters

<i>uplo</i>	(global, used in complex flavors only) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of sub(<i>A</i>) is stored; If <i>uplo</i> = 'L', lower triangle of sub(<i>A</i>) is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix sub(<i>A</i>) ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix sub(<i>B</i>) ($nrhs \geq 0$).
<i>d, e</i>	(local) REAL for pspttrs DOUBLE PRECISION for pdpttrs COMPLEX for pcpttrs DOUBLE COMPLEX for pzpttrs. Pointers into the local memory to arrays of dimension (<i>desca</i> (<i>nb_</i>)) each. These arrays contain details of the factorization as returned by <code>p?pttrf</code>
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501 or 502, then $dlen_ \geq 7$; else if <i>desca</i> (<i>dtype_</i>) = 1, then $dlen_ \geq 9$.
<i>b</i>	(local) Same type as <i>d, e</i> . Pointer into the local memory to an array of local dimension <i>b</i> (<i>lld_b</i> , <i>LOCc</i> (<i>nrhs</i>)). On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix sub(<i>B</i>).

<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb</i> (<i>dtype_</i>) = 502, then <i>dlen_</i> ≥ 7; else if <i>descb</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) REAL for <i>pspttrs</i> DOUBLE PRECISION for <i>pdpttrs</i> COMPLEX for <i>pcpttrs</i> DOUBLE COMPLEX for <i>pzpttrs</i> . Arrays of dimension (<i>laf</i>) and (<i>lwork</i>), respectively. The array <i>af</i> contains auxiliary Fillin space. Fillin is created during the factorization routine <i>p?pttrf</i> and this is stored in <i>af</i> . The array <i>work</i> is a workspace array.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be <i>laf</i> ≥ NB+2. If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> , must be at least $lwork \geq (10 + 2 * \min(100, nrhs)) * NPCOL + 4 * nrhs$.

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>x</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?dttrs

Solves a system of linear equations with a diagonally dominant-like tridiagonal distributed matrix using the factorization computed by p?dttrf.

Syntax

```
call psdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pddttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pcdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine `p?dttrs` solves for X one of the systems of equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where $\text{sub}(A) = (1:n, ja:ja+n-1)$; is a diagonally dominant-like tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by `p?dttrf`.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If *trans* = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X .
If *trans* = 'T', then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X .

	<p>If $trans = 'C'$, then $(sub(A))^H * X = sub(B)$ is solved for X.</p>
n	<p>(global) INTEGER. The order of the distributed submatrix $sub(A)$ ($n \geq 0$).</p>
$nrhs$	<p>(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $sub(B)$ ($nrhs \geq 0$).</p>
dl, d, du	<p>(local) REAL for psdttrs DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs DOUBLE COMPLEX for pzdttrs. Pointers to the local arrays of dimension $(desca(nb_))$ each. On entry, these arrays contain details of the factorization. Globally, $dl(1)$ and $du(n)$ are not referenced; dl and du must be aligned with d.</p>
ja	<p>(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).</p>
$desca$	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A. If $desca(dtype_) = 501$ or 502, then $dlen_ \geq 7$; else if $desca(dtype_) = 1$, then $dlen_ \geq 9$.</p>
b	<p>(local) Same type as d. Pointer into the local memory to an array of local dimension $b(ll_d_b, LOCC(nrhs))$. On entry, the array b contains the local pieces of the n-by-$nrhs$ right hand side distributed matrix $sub(B)$.</p>
ib	<p>(global) INTEGER. The row index in the global array B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).</p>
$descb$	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix B. If $descb(dtype_) = 502$, then $dlen_ \geq 7$;</p>

af, work else if *descb(dtype_) = 1*, then *dlen_ ≥ 9*.
 (local) REAL for *psdttrs*
 DOUBLE PRECISION for *pddttrs*
 COMPLEX for *pcdttrs*
 DOUBLE COMPLEX for *pzdttrs*.
 Arrays of dimension (*laf*) and (*lwork*), respectively.
 The array *af* contains auxiliary Fillin space. Fillin is created
 during the factorization routine *p?dttrf* and this is stored
 in *af*. If a linear system is to be solved using *p?dttrs* after
 the factorization routine, *af* must not be altered.
 The array *work* is a workspace array.

laf (local) INTEGER. The dimension of the array *af*.
 Must be *laf ≥*
 $NB * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$.
 If *laf* is not large enough, an error code will be returned
 and the minimum acceptable size will be returned in *af*(1).

lwork (local or global) INTEGER. The size of the array *work*, must
 be at least $lwork ≥ 10 * NPCOL + 4 * nrhs$.

Output Parameters

b On exit, this array contains the local pieces of the solution
 distributed matrix *x*.

work(1) On exit, *work*(1) contains the minimum value of *lwork*
 required for optimum performance.

info INTEGER. If *info*=0, the execution is successful. *info* <
 0:
 if the *i*th argument is an array and the *j*-th entry had an
 illegal value, then *info* = $-(i * 100 + j)$; if the *i*-th
 argument is a scalar and had an illegal value, then *info* =
 $-i$.

p?dbtrs

Solves a system of linear equations with a diagonally dominant-like banded distributed matrix using the factorization computed by p?dbtrf.

Syntax

```
call psdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pddbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pcdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine `p?dbtrs` solves for X one of the systems of equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like banded distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by `p?dbtrf`.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
 Indicates the form of the equations:
 If *trans* = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X .
 If *trans* = 'T', then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X .

	<p>If $trans = 'C'$, then $(sub(A))^H * X = sub(B)$ is solved for X.</p>
n	<p>(global) INTEGER. The order of the distributed submatrix $sub(A)$ ($n \geq 0$).</p>
bwl	<p>(global) INTEGER. The number of subdiagonals within the band of A</p> <p>($0 \leq bwl \leq n-1$).</p>
bwu	<p>(global) INTEGER. The number of superdiagonals within the band of A</p> <p>($0 \leq bwu \leq n-1$).</p>
$nrhs$	<p>(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $sub(B)$</p> <p>($nrhs \geq 0$).</p>
a, b	<p>(local)</p> <p>REAL for psdbtrs DOUBLE PRECISION for pddbtrs COMPLEX for pcdbtrs DOUBLE COMPLEX for pzdbtrs.</p> <p>Pointers into the local memory to arrays of local dimension $a(lld_a, LOCC(ja+n-1))$ and $b(lld_b, LOCC(nrhs))$, respectively.</p> <p>On entry, the array a contains details of the LU factorization of the band matrix A, as computed by $p?dbtrf$.</p> <p>On entry, the array b contains the local pieces of the right hand side distributed matrix $sub(B)$.</p>
ja	<p>(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).</p>
$desca$	<p>(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A.</p> <p>If $desca(dtype_) = 501$, then $dlen_ \geq 7$; else if $desca(dtype_) = 1$, then $dlen_ \geq 9$.</p>

<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb(dtype_)</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>descb(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) REAL for psdbtrs DOUBLE PRECISION for pddbtrs COMPLEX for pcdbtrs DOUBLE COMPLEX for pzdbtrs. Arrays of dimension (<i>laf</i>) and (<i>lwork</i>), respectively The array <i>af</i> contains auxiliary Fillin space. Fillin is created during the factorization routine p?dbtrf and this is stored in <i>af</i> . The array <i>work</i> is a workspace array.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> , must be at least $lwork \geq (\max(bwl, bwu))^2$.

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0:

if the i th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?trtrs

Solves a system of linear equations with a triangular distributed matrix.

Syntax

```
call pstrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)

call pdtrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)

call pctrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)

call pztrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine solves for X one of the following systems of linear equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is a triangular distributed matrix of order n , and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

A check is made to verify that $\text{sub}(A)$ is nonsingular.

Input Parameters

uplo (global) CHARACTER*1. Must be 'U' or 'L'.
Indicates whether $\text{sub}(A)$ is upper or lower triangular:

If $uplo = 'U'$, then $sub(A)$ is upper triangular.
 If $uplo = 'L'$, then $sub(A)$ is lower triangular.

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
 Indicates the form of the equations:
 If $trans = 'N'$, then $sub(A) * X = sub(B)$ is solved for X .
 If $trans = 'T'$, then $sub(A)^T * X = sub(B)$ is solved for X .
 If $trans = 'C'$, then $sub(A)^H * X = sub(B)$ is solved for X .

diag (global) CHARACTER*1. Must be 'N' or 'U'.
 If $diag = 'N'$, then $sub(A)$ is not a unit triangular matrix.
 If $diag = 'U'$, then $sub(A)$ is unit triangular.

n (global) INTEGER. The order of the distributed submatrix $sub(A)$ ($n \geq 0$).

nrhs (global) INTEGER. The number of right-hand sides; i.e., the number of columns of the distributed matrix $sub(B)$ ($nrhs \geq 0$).

a, b (local)
 REAL for pstrtrs
 DOUBLE PRECISION for pdtrtrs
 COMPLEX for pctrtrs
 DOUBLE COMPLEX for pztrtrs.
 Pointers into the local memory to arrays of local dimension $a(ll_d_a, LOCC(ja+n-1))$ and $b(ll_d_b, LOCC(jb+nrhs-1))$, respectively.
 The array a contains the local pieces of the distributed triangular matrix $sub(A)$.
 If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular matrix, and the strictly lower triangular part of $sub(A)$ is not referenced.
 If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $sub(A)$ is not referenced.
 If $diag = 'U'$, the diagonal elements of $sub(A)$ are also not referenced and are assumed to be 1.

	On entry, the array <i>b</i> contains the local pieces of the right hand side distributed matrix $\text{sub}(B)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	On exit, if <i>info</i> =0, $\text{sub}(B)$ is overwritten by the solution matrix <i>X</i> .
<i>info</i>	<p>INTEGER. If <i>info</i>=0, the execution is successful.</p> <p><i>info</i> < 0:</p> <p>if the <i>i</i>th argument is an array and the <i>j</i>th entry had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>;</p> <p><i>info</i> > 0:</p> <p>if <i>info</i> = <i>i</i>, the <i>i</i>-th diagonal element of $\text{sub}(A)$ is zero, indicating that the submatrix is singular and the solutions <i>x</i> have not been computed.</p>

Routines for Estimating the Condition Number

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

p?gecon

Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.

Syntax

```
call psgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
             liwork, info)

call pdgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
             liwork, info)

call pcgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
             lrwork, info)

call pzgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
             lrwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine estimates the reciprocal of the condition number of a general distributed real/complex matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ in either the 1-norm or infinity-norm, using the *LU* factorization computed by [p?getrf](#).

An estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|\text{sub}(A)\| \times \|(\text{sub}(A))^{-1}\|}$$

Input Parameters

norm (global) CHARACTER*1. Must be '1' or 'O' or 'I'.
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required.
 If *norm* = '1' or 'O', then the 1-norm is used;
 If *norm* = 'I', then the infinity-norm is used.

<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psgecon DOUBLE PRECISION for pdgecon COMPLEX for pcgecon DOUBLE COMPLEX for pzgecon. Pointer into the local memory to an array of dimension $a(lld_a, LOCC(ja+n-1))$. The array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P * L * U$; the unit diagonal elements of <i>L</i> are not stored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	(global) REAL for single precision flavors, DOUBLE PRECISION for double precision flavors. If <i>norm</i> = '1' or 'O', the 1-norm of the original distributed matrix $\text{sub}(A)$; If <i>norm</i> = 'I', the infinity-norm of the original distributed matrix $\text{sub}(A)$.
<i>work</i>	(local) REAL for psgecon DOUBLE PRECISION for pdgecon COMPLEX for pcgecon DOUBLE COMPLEX for pzgecon. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . For real flavors: <i>lwork</i> must be at least

$$lwork \geq 2*LOCr(n+mod(ia-1,mb_a))+$$

$$2*LOCc(n+mod(ja-1,nb_a))+max(2, max(nb_a*max(1,$$

$$ceil(NPROW-1, NPCOL)),$$

$$LOCc(n+mod(ja-1,nb_a))+nb_a*max(1, ceil(NPCOL-1,$$

$$NPROW))).$$

For complex flavors:

lwork must be at least

$$lwork \geq 2*LOCr(n+mod(ia-1,mb_a))+max(2,$$

$$max(nb_a*ceil(NPROW-1, NPCOL),$$

$$LOCc(n+mod(ja-1,nb_a))+ nb_a*ceil(NPCOL-1,$$

$$NPROW))).$$

LOCr and *LOCc* values can be computed using the ScaLAPACK tool function `numroc`; *NPROW* and *NPCOL* can be determined by calling the subroutine `blacs_gridinfo`.

iwork (local) INTEGER. Workspace array, DIMENSION (*liwork*).

Used in real flavors only.

liwork (local or global) INTEGER. The dimension of the array *iwork*; used in real flavors only. Must be at least

$$liwork \geq LOCr(n+mod(ia-1,mb_a)).$$

rwork (local) REAL for `pcgecon`

DOUBLE PRECISION for `pzgecon`

Workspace array, DIMENSION (*lrwork*). Used in complex flavors only.

lrwork (local or global) INTEGER. The dimension of the array *rwork*; used in complex flavors only. Must be at least

$$lrwork \geq 2*LOCc(n+mod(ja-1,nb_a)).$$

Output Parameters

rcond (global) REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The reciprocal of the condition number of the distributed matrix `sub(A)`. See Description.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

<code>iwork(1)</code>	On exit, <code>iwork(1)</code> contains the minimum value of <code>liwork</code> required for optimum performance (for real flavors).
<code>rwork(1)</code>	On exit, <code>rwork(1)</code> contains the minimum value of <code>lrwork</code> required for optimum performance (for complex flavors).
<code>info</code>	(global) INTEGER. If <code>info=0</code> , the execution is successful. <code>info < 0</code> : If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?pocon

Estimates the reciprocal of the condition number (in the 1 - norm) of a symmetric / Hermitian positive-definite distributed matrix.

Syntax

```
call pspocon( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
             liwork, info)

call pdpocon( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
             liwork, info)

call pcpocon( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
             lrwork, info)

call pzpocon( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
             lrwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by `p?potrf`.

An estimate is obtained for $||(\text{sub}(A))^{-1}||$, and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|sub(A)\| \times \|(sub(A))^{-1}\|}$$

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Must be 'U' or 'L'.</p> <p>Specifies whether the factor stored in sub(A) is upper or lower triangular.</p> <p>If <i>uplo</i> = 'U', sub(A) stores the upper triangular factor U of the Cholesky factorization $sub(A) = U^H * U$.</p> <p>If <i>uplo</i> = 'L', sub(A) stores the lower triangular factor L of the Cholesky factorization $sub(A) = L * L^H$.</p>
<i>n</i>	<p>(global) INTEGER. The order of the distributed submatrix sub(A) ($n \geq 0$).</p>
<i>a</i>	<p>(local)</p> <p>REAL for pspocon</p> <p>DOUBLE PRECISION for pdpocon</p> <p>COMPLEX for pcpocon</p> <p>DOUBLE COMPLEX for pzpocon.</p> <p>Pointer into the local memory to an array of dimension $a(lld_a, LOCC(ja+n-1))$.</p> <p>The array <i>a</i> contains the local pieces of the factors L or U from the Cholesky factorization $sub(A) = U^H * U$, or $sub(A) = L * L^H$, as computed by p?potrf.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(A), respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i>.</p>
<i>anorm</i>	<p>(global) REAL for single precision flavors,</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>The 1-norm of the symmetric/Hermitian distributed matrix sub(A).</p>
<i>work</i>	<p>(local)</p>

	<p>REAL for pspocon DOUBLE PRECISION for pdpocon COMPLEX for pcpocon DOUBLE COMPLEX for pzpocon.</p> <p>The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.</p>
<i>lwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>work</i>. For real flavors: <i>lwork</i> must be at least</p> $lwork \geq 2*LOCr(n+mod(ia-1,mb_a))+2*LOCc(n+mod(ja-1,nb_a))+\max(2,\max(nb_a*\text{ceil}(NPROW-1,NPCOL),LOCc(n+mod(ja-1,nb_a))+nb_a*\text{ceil}(NPCOL-1,NPROW))).$ <p>For complex flavors: <i>lwork</i> must be at least</p> $lwork \geq 2*LOCr(n+mod(ia-1,mb_a))+\max(2,\max(nb_a*\max(1,\text{ceil}(NPROW-1,NPCOL)),LOCc(n+mod(ja-1,nb_a))+nb_a*\max(1,\text{ceil}(NPCOL-1,NPROW)))).$
<i>iwork</i>	<p>(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.</p>
<i>liwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>iwork</i>; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ia-1,mb_a))$.</p>
<i>rwork</i>	<p>(local) REAL for pcpocon DOUBLE PRECISION for pzpocon Workspace array, DIMENSION (<i>lrwork</i>). Used in complex flavors only.</p>
<i>lrwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>rwork</i>; used in complex flavors only. Must be at least $lrwork \geq 2*LOCc(n+mod(ja-1,nb_a))$.</p>

Output Parameters

<i>rcond</i>	<p>(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.</p>
--------------	--------------------------------------------------------------------------------------------------------

	The reciprocal of the condition number of the distributed matrix $\text{sub}(A)$.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>iwork(1)</code>	On exit, <code>iwork(1)</code> contains the minimum value of <code>liwork</code> required for optimum performance (for real flavors).
<code>rwork(1)</code>	On exit, <code>rwork(1)</code> contains the minimum value of <code>lrwork</code> required for optimum performance (for complex flavors).
<code>info</code>	(global) INTEGER. If <code>info=0</code> , the execution is successful. <code>info < 0</code> : If the <code>i</code> th argument is an array and the <code>j</code> th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the <code>i</code> th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?trcon

Estimates the reciprocal of the condition number of a triangular distributed matrix in either 1-norm or infinity-norm.

Syntax

```
call pstrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
iwork, liwork, info)

call pdtrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
iwork, liwork, info)

call pctrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
rwork, lrwork, info)

call pztrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
rwork, lrwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine estimates the reciprocal of the condition number of a triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, in either the 1-norm or the infinity-norm.

The norm of $\text{sub}(A)$ is computed and an estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, then the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|\text{sub}(A)\| \times \|(\text{sub}(A))^{-1}\|}$$

Input Parameters

<i>norm</i>	<p>(global) CHARACTER*1. Must be '1' or 'O' or 'I'.</p> <p>Specifies whether the 1-norm condition number or the infinity-norm condition number is required.</p> <p>If <i>norm</i> = '1' or 'O', then the 1-norm is used;</p> <p>If <i>norm</i> = 'I', then the infinity-norm is used.</p>
<i>uplo</i>	<p>(global) CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.</p>
<i>diag</i>	<p>(global) CHARACTER*1. Must be 'N' or 'U'.</p> <p>If <i>diag</i> = 'N', $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', $\text{sub}(A)$ is unit triangular.</p>
<i>n</i>	<p>(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$, ($n \geq 0$).</p>
<i>a</i>	<p>(local)</p> <p>REAL for pstrcon</p> <p>DOUBLE PRECISION for pdtrcon</p> <p>COMPLEX for pctrcon</p> <p>DOUBLE COMPLEX for pztrcon.</p> <p>Pointer into the local memory to an array of dimension $a(lld_a, LOCC(ja+n-1))$.</p> <p>The array <i>a</i> contains the local pieces of the triangular distributed matrix $\text{sub}(A)$.</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced.</p>

	<p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced.</p> <p>If <i>diag</i> = 'U', the diagonal elements of sub(<i>A</i>) are also not referenced and are assumed to be 1.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _—). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	<p>(local)</p> <p>REAL for pstrcon</p> <p>DOUBLE PRECISION for pdtrcon</p> <p>COMPLEX for pctrcon</p> <p>DOUBLE COMPLEX for pztrcon.</p> <p>The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.</p>
<i>lwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>work</i>.</p> <p>For real flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb_a))+$ $LOCc(n+\text{mod}(ja-1,nb_a))+\max(2,$ $\max(nb_a*\max(1,\text{ceil}(NPROW-1,NPCOL)),$ $LOCc(n+\text{mod}(ja-1,nb_a))+nb_a*\max(1,\text{ceil}(NPCOL-1,$ $NPROW))).$ <p>For complex flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb_a))+\max(2,$ $\max(nb_a*\text{ceil}(NPROW-1,NPCOL),$ $LOCc(n+\text{mod}(ja-1,nb_a))+nb_a*\text{ceil}(NPCOL-1,$ $NPROW))).$
<i>iwork</i>	(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least
	$liwork \geq LOCr(n+\text{mod}(ia-1,mb_a)).$
<i>rwork</i>	(local) REAL for pcpccon

lrwork DOUBLE PRECISION for pzpocon
 Workspace array, DIMENSION (*lrwork*). Used in complex flavors only.
 (local or global) INTEGER. The dimension of the array *rwork*; used in complex flavors only. Must be at least
 $lrwork \geq LOCC(n + \text{mod}(ja-1, nb_a))$.

Output Parameters

rcond (global) REAL for single precision flavors.
 DOUBLE PRECISION for double precision flavors.
 The reciprocal of the condition number of the distributed matrix sub(*A*).

work(1) On exit, *work*(1) contains the minimum value of *lrwork* required for optimum performance.

iwork(1) On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance (for real flavors).

rwork(1) On exit, *rwork*(1) contains the minimum value of *lrwork* required for optimum performance (for complex flavors).

info (global) INTEGER. If *info*=0, the execution is successful.
info < 0:
 If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Refining the Solution and Estimating Its Error

This section describes the ScaLAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Solving Systems of Linear Equations](#)).

p?gerfs

Improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

```
call psgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork,
info)
```

```
call pdgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork,
info)
```

```
call pcgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork,
info)
```

```
call pzgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork,
info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine improves the computed solution to one of the systems of linear equations

$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$

$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B),$ or

$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ and provides error bounds and backward error estimates for the solution.

Here $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1)$, and $\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+\text{nrhs}-1)$.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
Specifies the form of the system of equations:

	<p>If $trans = 'N'$, the system has the form $sub(A) * sub(X) = sub(B)$ (No transpose);</p> <p>If $trans = 'T'$, the system has the form $sub(A)^T * sub(X) = sub(B)$ (Transpose);</p> <p>If $trans = 'C'$, the system has the form $sub(A)^H * sub(X) = sub(B)$ (Conjugate transpose).</p>
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $sub(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices $sub(B)$ and $sub(X)$ ($nrhs \geq 0$).
<i>a, af, b, x</i>	<p>(local)</p> <p>REAL for psgerfs</p> <p>DOUBLE PRECISION for pdgerfs</p> <p>COMPLEX for pcgerfs</p> <p>DOUBLE COMPLEX for pzgerfs.</p> <p>Pointers into the local memory to arrays of local dimension $a(lld_a, LOCc(ja+n-1))$, $af(lld_af, LOCc(jaf+n-1))$, $b(lld_b, LOCc(jb+nrhs-1))$, and $x(lld_x, LOCc(jx+nrhs-1))$, respectively.</p> <p>The array <i>a</i> contains the local pieces of the distributed matrix $sub(A)$.</p> <p>The array <i>af</i> contains the local pieces of the distributed factors of the matrix $sub(A) = P * L * U$ as computed by p?getrf.</p> <p>The array <i>b</i> contains the local pieces of the distributed matrix of right hand sides $sub(B)$.</p> <p>On entry, the array <i>x</i> contains the local pieces of the distributed solution matrix $sub(X)$.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global array <i>AF</i> indicating the first row and the first column of the submatrix <i>sub(AF)</i> , respectively.
<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix <i>sub(X)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>ipiv</i>	(local) INTEGER. Array, dimension $LOCr(m_af + mb_af)$. This array contains pivoting information as computed by p?getrf . If <i>ipiv</i> (<i>i</i>)= <i>j</i> , then the local row <i>i</i> was swapped with the global row <i>j</i> . This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <i>psgerfs</i> DOUBLE PRECISION for <i>pdgerfs</i> COMPLEX for <i>pcgerfs</i> DOUBLE COMPLEX for <i>pzgerfs</i> . The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . For real flavors: <i>lwork</i> must be at least $lwork \geq 3*LOCr(n+mod(ia-1,mb_a))$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb_a))$

<i>iwork</i>	(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ib-1,mb_b))$.
<i>rwork</i>	(local) REAL for pcgerfs DOUBLE PRECISION for pzgerfs Workspace array, DIMENSION (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n+mod(ib-1,mb_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCc(jb+nrhs-1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(<i>x</i>). If XTRUE is the true solution corresponding to sub(<i>x</i>), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in $(sub(X) - XTRUE)$ divided by the magnitude of the largest element in sub(<i>x</i>). The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix <i>x</i> . The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(<i>A</i>) or sub(<i>B</i>) that makes sub(<i>x</i>) an exact solution). This array is tied to the distributed matrix <i>x</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).

`rwork(1)` On exit, `rwork(1)` contains the minimum value of `lrwork` required for optimum performance (for complex flavors).

`info` (global) INTEGER. If `info=0`, the execution is successful.
`info < 0`:
 If the *i*th argument is an array and the *j*th entry had an illegal value, then `info = -(i*100+j)`; if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

p?porfs

Improves the computed solution to a system of linear equations with symmetric/Hermitian positive definite distributed matrix and provides error bounds and backward error estimates for the solution.

Syntax

```
call psporf(s, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, b, ib,
           jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)
call pdporfs(s, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, b, ib,
            jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)
call pcporf(s, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, b, ib,
           jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)
call pzporfs(s, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, b, ib,
           jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine `p?porfs` improves the computed solution to the system of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a real symmetric or complex Hermitian positive definite distributed matrix and

$$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1),$$

$$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+\text{nrhs}-1)$$

are right-hand side and solution submatrices, respectively. This routine also provides error bounds and backward error estimates for the solution.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(<i>A</i>) is stored. If <i>uplo</i> = 'U', sub(<i>A</i>) is upper triangular. If <i>uplo</i> = 'L', sub(<i>A</i>) is lower triangular.</p>
<i>n</i>	<p>(global) INTEGER. The order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).</p>
<i>nrhs</i>	<p>(global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices sub(<i>B</i>) and sub(<i>X</i>) ($nrhs \geq 0$).</p>
<i>a, af, b, x</i>	<p>(local) REAL for psporfs DOUBLE PRECISION for pdporfs COMPLEX for pcporfs DOUBLE COMPLEX for pzporfs. Pointers into the local memory to arrays of local dimension <i>a</i>(<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)), <i>af</i>(<i>lld_af</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)), <i>b</i>(<i>lld_b</i>, <i>LOCc</i>(<i>jb</i>+<i>nrhs</i>-1)), and <i>x</i>(<i>lld_x</i>, <i>LOCc</i>(<i>jx</i>+<i>nrhs</i>-1)), respectively. The array <i>a</i> contains the local pieces of the <i>n</i>-by-<i>n</i> symmetric/Hermitian distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced. The array <i>af</i> contains the factors <i>L</i> or <i>U</i> from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$, as computed by p?potrf. On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides sub(<i>B</i>).</p>

	On entry, the array x contains the local pieces of the solution vectors $\text{sub}(x)$.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .
iaf, jaf	(global) INTEGER. The row and column indices in the global array AF indicating the first row and the first column of the submatrix $\text{sub}(AF)$, respectively.
$descaf$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix AF .
ib, jb	(global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
$descb$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix B .
ix, jx	(global) INTEGER. The row and column indices in the global array x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
$descx$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix x .
$work$	(local) REAL for psporfs DOUBLE PRECISION for pdporfs COMPLEX for pcporfs DOUBLE COMPLEX for pzporfs. The array $work$ of dimension $(lwork)$ is a workspace array.
$lwork$	(local) INTEGER. The dimension of the array $work$. For real flavors: $lwork$ must be at least $lwork \geq 3*LOCr(n+\text{mod}(ia-1,mb_a))$ For complex flavors: $lwork$ must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb_a))$

<i>iwork</i>	(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ib-1,mb_b))$.
<i>rwork</i>	(local) REAL for pcporfs DOUBLE PRECISION for pzpors Workspace array, DIMENSION (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n+mod(ib-1,mb_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCc(jb+nrhs-1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(<i>x</i>). If XTRUE is the true solution corresponding to sub(<i>x</i>), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in $(sub(X) - XTRUE)$ divided by the magnitude of the largest element in $sub(X)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix <i>x</i> . The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(<i>A</i>) or sub(<i>B</i>) that makes sub(<i>x</i>) an exact solution). This array is tied to the distributed matrix <i>x</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).

`rwork(1)` On exit, `rwork(1)` contains the minimum value of `lrwork` required for optimum performance (for complex flavors).

`info` (global) INTEGER. If `info=0`, the execution is successful.
`info < 0`:
 If the i -th argument is an array and the j -th entry had an illegal value, then `info = -(i*100+j)`; if the i -th argument is a scalar and had an illegal value, then `info = -i`.

p?trrfs

Provides error bounds and backward error estimates for the solution to a system of linear equations with a distributed triangular coefficient matrix.

Syntax

```
call pstrrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pdtrrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pctrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)

call pztrrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine `p?trrfs` provides error bounds and backward error estimates for the solution to one of the systems of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

$$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B), \text{ or}$$

$$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B),$$

where `sub(A) = A(ia:ia+n-1, ja:ja+n-1)` is a triangular matrix,

$\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1)$, and
 $\text{sub}(X) = X(ix:ix+n-1, jx:jx+nrhs-1)$.

The solution matrix X must be computed by `p?trtrs` or some other means before entering this routine. The routine `p?trrfs` does not do iterative refinement because doing so cannot improve the backward error.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose); If <i>trans</i> = 'T', the system has the form $\text{sub}((A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose); If <i>trans</i> = 'C', the system has the form $\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides, that is, the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$).
<i>a, b, x</i>	(local) REAL for <code>pstrrfs</code> DOUBLE PRECISION for <code>pdtrrfs</code> COMPLEX for <code>pctrfs</code> DOUBLE COMPLEX for <code>pztrrfs</code> . Pointers into the local memory to arrays of local dimension $a(lld_a, LOCC(ja+n-1))$, $b(lld_b, LOCC(jb+nrhs-1))$, and $x(lld_x, LOCC(jx+nrhs-1))$, respectively.

The array *a* contains the local pieces of the original triangular distributed matrix $\text{sub}(A)$.

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

If *diag* = 'U', the diagonal elements of $\text{sub}(A)$ are also not referenced and are assumed to be 1.

On entry, the array *b* contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$.

On entry, the array *x* contains the local pieces of the solution vectors $\text{sub}(X)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _—). The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _—). The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _—). The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	(local) REAL for pstrrfs DOUBLE PRECISION for pdtrrfs COMPLEX for pctrfs DOUBLE COMPLEX for pztrfs. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.

<i>lwork</i>	<p>(local) INTEGER. The dimension of the array <i>work</i>. For real flavors: <i>lwork</i> must be at least $lwork \geq 3*LOCr(n+mod(ia-1,mb_a))$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb_a))$</p>
<i>iwork</i>	<p>(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.</p>
<i>liwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>iwork</i>; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ib-1,mb_b))$.</p>
<i>rwork</i>	<p>(local) REAL for pctrdfs DOUBLE PRECISION for pztrdfs Workspace array, DIMENSION (<i>lrwork</i>). Used in complex flavors only.</p>
<i>lrwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>rwork</i>; used in complex flavors only. Must be at least $lrwork \geq LOCr(n+mod(ib-1,mb_b))$.</p>

Output Parameters

<i>ferr, berr</i>	<p>REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCc(jb+nrhs-1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(<i>x</i>). If XTRUE is the true solution corresponding to sub(<i>x</i>), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in (sub(<i>x</i>) - XTRUE) divided by the magnitude of the largest element in sub(<i>x</i>). The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix <i>x</i>.</p>
-------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to the distributed matrix <i>X</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> (1)	On exit, <i>rwork</i> (1) contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

Routines for Matrix Inversion

This sections describes ScaLAPACK routines that compute the inverse of a matrix based on the previously obtained factorization. Note that it is not recommended to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

p?getri

Computes the inverse of a LU-factored distributed matrix.

Syntax

```
call psgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pdgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pcgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pzgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes the inverse of a general distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the LU factorization computed by `p?getrf`. This method inverts U and then computes the inverse of $\text{sub}(A)$ by solving the system

$$\text{inv}(\text{sub}(A)) * L = \text{inv}(U)$$

for $\text{inv}(\text{sub}(A))$.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for <code>psgetri</code> DOUBLE PRECISION for <code>pdgetri</code> COMPLEX for <code>pcgetri</code> DOUBLE COMPLEX for <code>pzgetri</code> . Pointer into the local memory to an array of local dimension $a(lld_a, LOCC(ja+n-1))$. On entry, the array <i>a</i> contains the local pieces of the L and U obtained by the factorization $\text{sub}(A) = P * L * U$ computed by <code>p?getrf</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <code>psgetri</code> DOUBLE PRECISION for <code>pdgetri</code> COMPLEX for <code>pcgetri</code> DOUBLE COMPLEX for <code>pzgetri</code> . The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> must be at least

$lwork \geq LOCr(n + \text{mod}(ia-1, mb_a)) * nb_a$.

The array *work* is used to keep at most an entire column block of sub(*A*).

iwork

(local) INTEGER. Workspace array used for physically transposing the pivots, DIMENSION (*liwork*).

liwork

(local or global) INTEGER. The dimension of the array *iwork*. The minimal value *liwork* of is determined by the following code:

```
if NPROW == NPCOL then
```

```
    liwork = LOCc(n_a + mod(ja-1, nb_a)) + nb_a
```

```
else
```

```
    liwork = LOCc(n_a + mod(ja-1, nb_a)) +
```

```
max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)), nb_a)
```

```
end if
```

where *lcm* is the least common multiple of process rows and columns (NPROW and NPCOL).

Output Parameters

ipiv

(local) INTEGER.

Array, dimension ($LOCr(m_a) + mb_a$).

This array contains the pivoting information.

If *ipiv*(*i*)=*j*, then the local row *i* was swapped with the global row *j*.

This array is tied to the distributed matrix *A*.

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1)

On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance.

info

(global) INTEGER. If *info*=0, the execution is successful. *info* < 0:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = i$, $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?potri

Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.

Syntax

```
call pspotri(uplo, n, a, ia, ja, desca, info)
call pdpotri(uplo, n, a, ia, ja, desca, info)
call pcpotri(uplo, n, a, ia, ja, desca, info)
call pzpotri(uplo, n, a, ia, ja, desca, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by `p?potrf`.

Input Parameters

uplo (global) CHARACTER*1. Must be 'U' or 'L'.
Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored.
If *uplo* = 'U', upper triangle of $\text{sub}(A)$ is stored. If *uplo* = 'L', lower triangle of $\text{sub}(A)$ is stored.

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pspotri DOUBLE PRECISION for pdpotri COMPLEX for pcpotri DOUBLE COMPLEX for pzpotri. Pointer into the local memory to an array of local dimension $a(\text{lld_a}, \text{LOCc}(ja+n-1))$. On entry, the array <i>a</i> contains the local pieces of the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by p?potrf.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of $\text{sub}(A)$.
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then $\text{info} = -(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then $\text{info} = -i$. <i>info</i> > 0: If $\text{info} = i$, the (<i>i</i> , <i>i</i>) element of the factor <i>U</i> or <i>L</i> is zero, and the inverse could not be computed.

p?trtri

Computes the inverse of a triangular distributed matrix.

Syntax

```
call pstrtri(uplo, diag, n, a, ia, ja, desca, info)
call pdtrtri(uplo, diag, n, a, ia, ja, desca, info)
call pctrtri(uplo, diag, n, a, ia, ja, desca, info)
call pztrtri(uplo, diag, n, a, ia, ja, desca, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the inverse of a real or complex upper or lower triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. Specifies whether or not the distributed matrix $\text{sub}(A)$ is unit triangular. If <i>diag</i> = 'N', then $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pstrtri DOUBLE PRECISION for pdtrtri COMPLEX for pctrtri DOUBLE COMPLEX for pztrtri.

Pointer into the local memory to an array of local dimension
 $a(lld_a, LOCC(ja+n-1))$.

The array a contains the local pieces of the triangular distributed matrix $\text{sub}(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix to be inverted, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desca$

(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .

Output Parameters

a

On exit, overwritten by the (triangular) inverse of the original matrix.

$info$

(global) INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, $A(ia+k-1, ja+k-1)$ is exactly zero. The triangular matrix $\text{sub}(A)$ is singular and its inverse can not be computed.

Routines for Matrix Equilibration

ScaLAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

p?geequ

Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.

Syntax

```
call psgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pdgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pcgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pzgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes row and column scalings intended to equilibrate an m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

$r(i)$ and $c(j)$ are restricted to be between $SMINUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of $\text{sub}(A)$ but works well in practice.

The auxiliary function `p?laqge` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for <code>psgeequ</code>

DOUBLE PRECISION for pdgeequ

COMPLEX for pcgeequ

DOUBLE COMPLEX for pzgeequ .

Pointer into the local memory to an array of local dimension
 $a(lld_a, LOCc(ja+n-1))$.

The array a contains the local pieces of the m -by- n distributed matrix whose equilibration factors are to be computed.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desca$

(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .

Output Parameters

r, c

(local) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

Arrays, dimension $LOCr(m_a)$ and $LOCc(n_a)$, respectively.

If $info = 0$, or $info > ia+m-1$, the array $r(ia:ia+m-1)$ contains the row scale factors for $\text{sub}(A)$. r is aligned with the distributed matrix A , and replicated across every process column. r is tied to the distributed matrix A .

If $info = 0$, the array $c(ja:ja+n-1)$ contains the column scale factors for $\text{sub}(A)$. c is aligned with the distributed matrix A , and replicated down every process row. c is tied to the distributed matrix A .

$rowcnd, colcnd$

(global) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

If $info = 0$ or $info > ia+m-1$, $rowcnd$ contains the ratio of the smallest $r(i)$ to the largest $r(i)$ ($ia \leq i \leq$

$ia+m-1$). If $rowcnd \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by $r(ia:ia+m-1)$.

If $info = 0$, $colcnd$ contains the ratio of the smallest $c(j)$ to the largest $c(j)$ ($ja \leq j \leq ja+n-1$).

If $colcnd \geq 0.1$, it is not worth scaling by $c(ja:ja+n-1)$.

<i>amax</i>	<p>(global) REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. Absolute value of the largest matrix element. If <i>amax</i> is very close to overflow or very close to underflow, the matrix should be scaled.</p>
<i>info</i>	<p>(global) INTEGER. If <i>info</i>=0, the execution is successful. <i>info</i> < 0: If the <i>i</i>th argument is an array and the <i>j</i>th entry had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>. <i>info</i> > 0: If <i>info</i> = <i>i</i> and <i>i</i> ≤ <i>m</i>, the <i>i</i>th row of the distributed matrix sub(<i>A</i>) is exactly zero; <i>i</i> > <i>m</i>, the (<i>i</i>-<i>m</i>)th column of the distributed matrix sub(<i>A</i>) is exactly zero.</p>

p?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.

Syntax

```
call pspoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pdpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pcpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pzpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ and reduce its condition number (with respect to the two-norm). The output arrays sr and sc return the row and column scale factors

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled distributed matrix B with elements $b_{ij} = s(i) * a_{ij} * s(j)$ has ones on the diagonal.

This choice of sr and sc puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function `p?laqsy` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for <code>pspoequ</code> DOUBLE PRECISION for <code>pdpoequ</code> COMPLEX for <code>pcpoequ</code> DOUBLE COMPLEX for <code>pzpoequ</code> . Pointer into the local memory to an array of local dimension $a(\text{lld_a}, \text{LOCc}(\text{ja}+n-1))$. The array a contains the n -by- n symmetric/Hermitian positive definite distributed matrix $\text{sub}(A)$ whose scaling factors are to be computed. Only the diagonal elements of $\text{sub}(A)$ are referenced.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
desca	(global and local) INTEGER array, dimension (dlen_). The array descriptor for the distributed matrix A .

Output Parameters

<i>sr, sc</i>	<p>(local)</p> <p>REAL for single precision flavors; DOUBLE PRECISION for double precision flavors.</p> <p>Arrays, dimension $LOCr(m_a)$ and $LOCc(n_a)$, respectively.</p> <p>If $info = 0$, the array $sr(ia:ia+n-1)$ contains the row scale factors for sub(A). sr is aligned with the distributed matrix A, and replicated across every process column. sr is tied to the distributed matrix A.</p> <p>If $info = 0$, the array $sc(ja:ja+n-1)$ contains the column scale factors for sub(A). sc is aligned with the distributed matrix A, and replicated down every process row. sc is tied to the distributed matrix A.</p>
<i>scond</i>	<p>(global)</p> <p>REAL for single precision flavors; DOUBLE PRECISION for double precision flavors.</p> <p>If $info = 0$, <i>scond</i> contains the ratio of the smallest $sr(i)$ (or $sc(j)$) to the largest $sr(i)$ (or $sc(j)$), with $ia \leq i \leq ia+n-1$ and $ja \leq j \leq ja+n-1$.</p> <p>If $scond \geq 0.1$ and <i>amax</i> is neither too large nor too small, it is not worth scaling by sr (or sc).</p>
<i>amax</i>	<p>(global)</p> <p>REAL for single precision flavors; DOUBLE PRECISION for double precision flavors.</p> <p>Absolute value of the largest matrix element. If <i>amax</i> is very close to overflow or very close to underflow, the matrix should be scaled.</p>
<i>info</i>	<p>(global) INTEGER.</p> <p>If $info=0$, the execution is successful.</p> <p>$info < 0$:</p> <p>If the i-th argument is an array and the j-th entry had an illegal value, then $info = -(i*100+j)$; if the i-th argument is a scalar and had an illegal value, then $info = -i$.</p> <p>$info > 0$:</p> <p>If $info = k$, the k-th diagonal entry of sub(A) is nonpositive.</p>

Orthogonal Factorizations

This section describes the ScaLAPACK routines for the QR (RQ) and LQ (QL) factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included. For the mathematical definition of the factorizations, see the respective LAPACK sections or refer to [SLUG].

Table 6-3 lists ScaLAPACK routines that perform orthogonal factorization of matrices.

p?geqrf

Computes the QR factorization of a general m -by- n matrix.

Syntax

```
call psgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine forms the QR factorization of a general m -by- n distributed matrix `sub(A) = A(ia:ia+m-1, ja:ja+n-1)` as

$$A = Q * R$$

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix <code>sub(A)</code> ; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix <code>sub(A)</code> ; ($n \geq 0$).
<i>a</i>	(local) REAL for <code>psgeqrf</code> DOUBLE PRECISION for <code>pdgeqrf</code> COMPLEX for <code>pcgeqrf</code> DOUBLE COMPLEX for <code>pzgeqrf</code> . Pointer into the local memory to an array of local dimension (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). Contains the local pieces of the distributed matrix <code>sub(A)</code> to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <code>a</code> indicating the first row and the first column of the submatrix <code>A(ia:ia+m-1, ja:ja+n-1)</code> , respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*

work (local).
 REAL for psgeqrf
 DOUBLE PRECISION for pdgeqrf.
 COMPLEX for pcgeqrf.
 DOUBLE COMPLEX for pzgeqrf
 Workspace array of dimension *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least $lwork \geq nb_a * (mp0+nq0+nb_a)$, where
 $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW})$,
 $iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL})$,
 $mp0 = \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW})$,
 $nq0 = \text{numroc}(n+icoff, nb_a, \text{MYCOL}, iacol, \text{NPCOL})$,
 and numroc , indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine `blacs_gridinfo`.
 If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a The elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m,n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau (local)
 REAL for psgeqrf
 DOUBLE PRECISION for pdgeqrf
 COMPLEX for pcgeqrf
 DOUBLE COMPLEX for pzgeqrf.

	Array, DIMENSION $LOCc(ja+\min(m,n)-1)$. Contains the scalar factor τ of elementary reflectors. τ is tied to the distributed matrix A .
$work(1)$	On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0, the execution is successful. < 0, if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(j) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

p?geqpf

Computes the QR factorization of a general m -by- n matrix with pivoting.

Syntax

```
call psgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pdgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pcgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pzgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine forms the QR factorization with column pivoting of a general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ as

$$\text{sub}(A) * P = Q * R$$

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for psgeqpf DOUBLE PRECISION for pdgeqpf COMPLEX for pcgeqpf DOUBLE COMPLEX for pzgeqpf. Pointer into the local memory to an array of local dimension $(\text{lld}_a, \text{LOCc}(\text{ja}+n-1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$, respectively.
desca	(global and local) INTEGER array, dimension $(\text{dlen}_\text{ })$. The array descriptor for the distributed matrix A .
work	(local). REAL for psgeqpf DOUBLE PRECISION for pdgeqpf. COMPLEX for pcgeqpf. DOUBLE COMPLEX for pzgeqpf Workspace array of dimension lwork .
lwork	(local or global) INTEGER, dimension of work , must be at least <i>For real flavors:</i> $\text{lwork} \geq \max(3, \text{mp0} + nq0) + \text{LOCc}(\text{ja}+n-1) + nq0$. <i>For complex flavors:</i> $\text{lwork} \geq \max(3, \text{mp0} + nq0)$.

Here

```
iroff = mod(ia-1, mb_a), icoeff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW
),
nq0 = numroc(n+icoeff, nb_a, MYCOL, iacol, NPCOL),
LOCc(ja+n-1) = numroc(ja+n-1, nb_a,
MYCOL, csrc_a, NPCOL), and numroc, indxg2p are
ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL
can be determined by calling the subroutine blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	The elements on and above the diagonal of sub(<i>A</i>) contain the min(<i>m</i> , <i>n</i>)-by- <i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if <i>m</i> ≥ <i>n</i>); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>ipiv</i>	(local) INTEGER. Array, DIMENSION LOCc(ja+n-1). <i>ipiv</i> (<i>i</i>) = <i>k</i> , the local <i>i</i> -th column of sub(<i>A</i>)* <i>P</i> was the global <i>k</i> -th column of sub(<i>A</i>). <i>ipiv</i> is tied to the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psgeqpf DOUBLE PRECISION for pdgeqpf COMPLEX for pcgeqpf DOUBLE COMPLEX for pzgeqpf. Array, DIMENSION LOCc(ja+min(<i>m</i> , <i>n</i>)-1)). Contains the scalar factor <i>tau</i> of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .

`work(1)` On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info` (global) INTEGER.
 = 0, the execution is successful.
 < 0, if the i -th argument is an array and the j -entry had an illegal value, then `info` = - ($i * 100 + j$), if the i -th argument is a scalar and had an illegal value, then `info` = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n),$$

Each $H(i)$ has the form

$$H = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i-1:ia+m-1, ja+i-1)$.

The matrix P is represented in `jpvt` as follows: if `jpvt(j) = i` then the j -th column of P is the i -th canonical unit vector.

p?orgqr

Generates the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
call psorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by [p?geqrf](#).

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Pointer into the local memory to an array of local dimension $(lld_a, LOCC(ja+n-1))$. The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Array, DIMENSION $LOCC(ja+k-1)$. Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by p?geqrf . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> .

Must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$,
where

```
iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1,
nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol,
NPCOL);
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.
```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	Contains the local pieces of the m -by- n distributed matrix Q .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of $lwork$ required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
call pcungqr( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungqr( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by [p?geqrf](#).

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) COMPLEX for <code>pcungqr</code> DOUBLE COMPLEX for <code>pzungqr</code> Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcungqr DOUBLE COMPLEX for pzungqr Array, DIMENSION <i>LOCc(ja+k-1)</i> . Contains the scalar factor <i>tau(j)</i> of elementary reflectors <i>H(j)</i> as returned by p?geqrf . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for pcungqr DOUBLE COMPLEX for pzungqr Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW)$, $nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla .

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
----------	---------------------------------------------------------------------------------------

`work(1)` On exit `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info` (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -entry had an illegal value, then `info` = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then `info` = $-i$.

p?ormqr

Multiplies a general matrix by the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

call psormqr(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*,
`work`, `lwork`, `info`)

call pdormqr(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*,
`work`, `lwork`, `info`)

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine overwrites the general real m -by- n distributed matrix `sub(C)` = `C(ic:ic+m-1,jc:jc+n-1)` with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^T * sub(C)$	$sub(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$

as returned by `p?geqrf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

`side` (global) CHARACTER

	<p>= 'L' : Q or Q^T is applied from the left.</p> <p>= 'R' : Q or Q^T is applied from the right.</p>
<i>trans</i>	<p>(global) CHARACTER</p> <p>= 'N', no transpose, Q is applied.</p> <p>= 'T', transpose, Q^T is applied.</p>
<i>m</i>	<p>(global) INTEGER. The number of rows in the distributed matrix <code>sub(c)</code> ($m \geq 0$).</p>
<i>n</i>	<p>(global) INTEGER. The number of columns in the distributed matrix <code>sub(c)</code> ($n \geq 0$).</p>
<i>k</i>	<p>(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints:</p> <p>If <i>side</i> = 'L', $m \geq k \geq 0$</p> <p>If <i>side</i> = 'R', $n \geq k \geq 0$.</p>
<i>a</i>	<p>(local)</p> <p>REAL for <code>psormqr</code></p> <p>DOUBLE PRECISION for <code>pdormqr</code>.</p> <p>Pointer into the local memory to an array of dimension (<code>lld_a</code>, <code>LOCc(ja+k-1)</code>). The j-th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.</p> <p>If <i>side</i> = 'L', $lld_a \geq \max(1, LOCr(ia+m-1))$</p> <p>If <i>side</i> = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for <code>psormqr</code></p> <p>DOUBLE PRECISION for <code>pdormqr</code></p> <p>Array, DIMENSION <code>LOCc(ja+k-1)</code>.</p>

	Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by <code>p?geqrf</code> . τ is tied to the distributed matrix A .
c	(local) REAL for <code>psormqr</code> DOUBLE PRECISION for <code>pdormqr</code> Pointer into the local memory to an array of local dimension $(lld_c, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix <code>sub(C)</code> to be factored.
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix c , respectively.
$desc$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix c .
$work$	(local) REAL for <code>psormqr</code> DOUBLE PRECISION for <code>pdormqr</code> . Workspace array of dimension of $lwork$.
$lwork$	(local or global) INTEGER, dimension of $work$, must be at least: if $side = 'L'$, $lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0+mpc0)*nb_a + nb_a*nb_a)$ else if $side = 'R'$, $lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0+\max(npa0+\text{numroc}(\text{numroc}(n+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a)$ end if where $lcmq = lcm/NPCOL \text{ with } lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$

```

npa0= numroc(n+iroffa, mb_a, MYROW, iarow,
NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0= numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0= numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p_xerbla`.

Output Parameters

<i>c</i>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q^T$, or $\text{sub}(C) \cdot Q$.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unmqr

Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
call pcunmqr( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )
```

```
call pzunmqr( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine overwrites the general complex m -by- n distributed matrix `sub (C) = C(ic:ic+m-1, jc:jc+n-1)` with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$ as returned by `p?geqrf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix <code>sub(C)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <code>sub(C)</code> ($n \geq 0$).

<i>k</i>	<p>(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints:</p> <p>If <i>side</i> = 'L', $m \geq k \geq 0$</p> <p>If <i>side</i> = 'R', $n \geq k \geq 0$.</p>
<i>a</i>	<p>(local)</p> <p>COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr.</p> <p>Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>k</i>-1)). The <i>j</i>-th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja + k - 1$, as returned by p?geqrf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.</p> <p>If <i>side</i> = 'L', $lld_a \geq \max(1, LOCr(ia+m-1))$</p> <p>If <i>side</i> = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr</p> <p>Array, DIMENSION <i>LOCc</i>(<i>ja</i>+<i>k</i>-1)).</p> <p>Contains the scalar factor <i>tau</i>(<i>j</i>) of elementary reflectors $H(j)$ as returned by p?geqrf. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local)</p> <p>COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr.</p> <p>Pointer into the local memory to an array of local dimension (<i>lld_c</i>, <i>LOCc</i>(<i>jc</i>+<i>n</i>-1)).</p> <p>Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.</p>

<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a$ else if <i>side</i> = 'R', $lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a$ end if where <i>lcmq</i> = <i>lcm</i> /NPCOL with <i>lcm</i> = <i>ilcm</i> (NPROW, NPCOL), <i>iroffa</i> = mod(<i>ia</i> -1, <i>mb_a</i>), <i>icoffa</i> = mod(<i>ja</i> -1, <i>nb_a</i>), <i>iarow</i> = indxg2p(<i>ia</i> , <i>mb_a</i> , MYROW, <i>rsrc_a</i> , NPROW), <i>npa0</i> = numroc(<i>n</i> + <i>iroffa</i> , <i>mb_a</i> , MYROW, <i>iarow</i> , NPROW), <i>iroffc</i> = mod(<i>ic</i> -1, <i>mb_c</i>), <i>icoffc</i> = mod(<i>jc</i> -1, <i>nb_c</i>), <i>icrow</i> = indxg2p(<i>ic</i> , <i>mb_c</i> , MYROW, <i>rsrc_c</i> , NPROW), <i>iccol</i> = indxg2p(<i>jc</i> , <i>nb_c</i> , MYCOL, <i>csrc_c</i> , NPCOL), <i>mpc0</i> = numroc(<i>m</i> + <i>iroffc</i> , <i>mb_c</i> , MYROW, <i>icrow</i> , NPROW), <i>nqc0</i> = numroc(<i>n</i> + <i>icoffc</i> , <i>nb_c</i> , MYCOL, <i>iccol</i> , NPCOL), <i>ilcm</i> , <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> .

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

c	Overwritten by the product $Q^* \text{sub}(C)$, or $Q^{H*} \text{sub}(C)$, or $\text{sub}(C) * Q^H$, or $\text{sub}(C) * Q$.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?gelqf

Computes the LQ factorization of a general rectangular matrix.

Syntax

```
call psgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine computes the LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ia:ia+n-1) = L * Q$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)). Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A((ia:ia+m-1, ja:ja+n-1))$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $iroff = \text{mod}(ia-1, mb_a),$ $icoff = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb_a, MYROW, iarow, NPROW),$ $nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL)$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	The elements on and below the diagonal of <code>sub(A)</code> contain the m by $\min(m,n)$ lower trapezoidal matrix L (L is lower trapezoidal if $m \leq n$); the elements above the diagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local) REAL for <code>psgelqf</code> DOUBLE PRECISION for <code>pdgelqf</code> COMPLEX for <code>pcgelqf</code> DOUBLE COMPLEX for <code>pzgelqf</code> Array, DIMENSION <code>LOCr(ia+min(m, n)-1)</code> . Contains the scalar factors of elementary reflectors. <code>tau</code> is tied to the distributed matrix <code>A</code> .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info</code> = - ($i*100+j$), if the i -th argument is a scalar and had an illegal value, then <code>info</code> = - i .

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia+k-1)*H(ia+k-2)*\dots*H(ia),$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i-1:ia+i-1, ja+n-1)$, and τ in $\tau(ia+i-1)$.

p?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call psorglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

```
call pdorglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by p?gelqf.

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq m \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) REAL for psorglq

DOUBLE PRECISION for `pdorglq`
 Pointer into the local memory to an array of local dimension
 (`lld_a`, `LOCc (ja+n-1)`). On entry, the i -th row must
 contain the vector which defines the elementary reflector
 $H(i)$, $ia \leq i \leq ia+k-1$, as returned by `p?gelqf` in the k rows
 of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

`ia, ja` (global) INTEGER. The row and column indices in the global
 array `a` indicating the first row and the first column of the
 submatrix $A((ia:ia+m-1, ja:ja+n-1))$, respectively.

`desca` (global and local) INTEGER array, dimension (`dlen_`). The
 array descriptor for the distributed matrix A .

`work` (local)
 REAL for `psorglq`
 DOUBLE PRECISION for `pdorglq`
 Workspace array of dimension of `lwork`.

`lwork` (local or global) INTEGER, dimension of `work`, must be at
 least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where
 $iroffa = \text{mod}(ia-1, mb_a)$,
 $icoffa = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW})$,
 $iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL})$,
 $mpa0 = \text{numroc}(m + iroffa, mb_a, \text{MYROW}, iarow, \text{NPROW})$,
 $nqa0 = \text{numroc}(n + icoffa, nb_a, \text{MYCOL}, iacol, \text{NPCOL})$
`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`,
`MYCOL`, `NPROW` and `NPCOL` can be determined by calling the
 subroutine `blacs_gridinfo`.
 If `lwork = -1`, then `lwork` is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by `p?xerbla`.

Output Parameters

`a` Contains the local pieces of the m -by- n distributed matrix Q
 to be factored.

<i>tau</i>	<p>(local)</p> <p>REAL for psorglq DOUBLE PRECISION for pdorglq Array, DIMENSION <i>LOCr</i>(<i>ia</i>+<i>k</i>-1). Contains the scalar factors <i>tau</i> of elementary reflectors $H(i)$. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>work</i> (1)	<p>On exit, <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance.</p>
<i>info</i>	<p>(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <i>info</i> = -(<i>i</i>* 100+<i>j</i>), if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.</p>

p?unglq

Generates the unitary matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call pcunglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzunglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine generates the whole or part of *m*-by-*n* complex distributed matrix *Q* denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first *m* rows of a product of *k* elementary reflectors of order *n*

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by p?gelqf.

Input Parameters

m (global) INTEGER. The number of rows in the submatrix sub(*Q*) (*m*≥0).

<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq m \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for pcunglq DOUBLE COMPLEX for pzunglq Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)). On entry, the <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunglq DOUBLE COMPLEX for pzunglq Array, DIMENSION <i>LOCr</i> (<i>ia</i> + <i>k</i> -1)). Contains the scalar factors <i>tau</i> of elementary reflectors $H(i)$. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for pcunglq DOUBLE COMPLEX for pzunglq Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}),$ $iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}),$ $mpa0 = \text{numroc}(m+iroffa, mb_a, \text{MYROW}, iarow, \text{NPROW}),$

`nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)`
`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.
 If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info</code> = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ormlq

Multiplies a general matrix by the orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call psormlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work,
             lwork, info)
```

```
call pdormlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work,
             lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by `p?gelqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER
 $= 'L'$: Q or Q^T is applied from the left.
 $= 'R'$: Q or Q^T is applied from the right.

trans (global) CHARACTER
 $= 'N'$, no transpose, Q is applied.
 $= 'T'$, transpose, Q^T is applied.

m (global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).

n (global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:
If $side = 'L'$, $m \geq k \geq 0$
If $side = 'R'$, $n \geq k \geq 0$.

a (local)
REAL for `psormlq`
DOUBLE PRECISION for `pdormlq`.
Pointer into the local memory to an array of dimension
 $(lld_a, LOCC(ja+m-1))$, if $side = 'L'$ and $(lld_a, LOCC(ja+n-1))$, if $side = 'R'$. The i -th row must contain

	<p>the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	<p>(local)</p> <p>REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code> Array, DIMENSION $LOCc(ja+k-1)$. Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by <code>p?gelqf</code>. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local)</p> <p>REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code> Pointer into the local memory to an array of local dimension ($lld_c, LOCc(jc+n-1)$). Contains the local pieces of the distributed matrix $sub(c)$ to be factored.</p>
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	<p>(local)</p> <p>REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code>. Workspace array of dimension of <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER, dimension of the array <i>work</i>; must be at least: If <i>side</i> = 'L',</p>

```

lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0+max mqa0)+
numroc(numroc(m + iroffc, mb_a, 0, 0, NPROW),
mb_a, 0, 0, lcmp), nqc0))* mb_a) + mb_a*mb_a
else if side = 'R',
lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0+nqc0)*mb_a
+ mb_a*mb_a
end if
where
lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),

calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER.

= 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmlq

Multiplies a general matrix by the unitary matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call pcunmlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )

call pzunmlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine overwrites the general complex m -by- n distributed matrix sub (C) = C ($ic:ic+m-1, jc:jc+n-1$) with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by p?gelqf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$ (global) CHARACTER
 = 'L': Q or Q^H is applied from the left.
 = 'R': Q or Q^H is applied from the right.

$trans$ (global) CHARACTER

	='N', no transpose, Q is applied. ='C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix <code>sub(c)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <code>sub(c)</code> ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for <code>pcunmlq</code> DOUBLE COMPLEX for <code>pzunmlq</code> . Pointer into the local memory to an array of dimension <code>(lld_a, LOCc(ja+m-1))</code> , if <i>side</i> = 'L', and <code>(lld_a, LOCc(ja+n-1))</code> , if <i>side</i> = 'R', where $lld_a \geq \max(1, LOCr(ia+k-1))$. The <i>i</i> -th column must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the <i>k</i> rows of its distributed matrix argument <code>A(ia:ia+k-1, ja:*)</code> . <code>A(ia:ia+k-1, ja:*)</code> is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension <code>(dlen_)</code> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcunmlq</code> DOUBLE COMPLEX for <code>pzunmlq</code> Array, DIMENSION <code>LOCc(ia+k-1)</code> . Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by <code>p?gelqf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local)

COMPLEX for pcunmlq
DOUBLE COMPLEX for pzunmlq.
Pointer into the local memory to an array of local dimension
(*lld_c*, *LOCc(jc+n-1)*).
Contains the local pieces of the distributed matrix sub(*c*)
to be factored.

ic, jc (global) INTEGER. The row and column indices in the global
array *c* indicating the first row and the first column of the
submatrix *c*, respectively.

descc (global and local) INTEGER array, dimension (*dlen_*). The
array descriptor for the distributed matrix *c*.

work (local)
COMPLEX for pcunmlq
DOUBLE COMPLEX for pzunmlq.
Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of the array *work*;
must be at least:
If *side* = 'L',
 $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max mqa0) +$
 $\text{numroc}(\text{numroc}(m + iroffa, mb_a, 0, 0, NPROW),$
 $mb_a, 0, 0, lcmp), nqc0)) * mb_a + mb_a * mb_a$
else if *side* = 'R',
 $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 +$
 $nqc0) * mb_a + mb_a * mb_a$
end if
where
 $lcmp = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(ia - 1, mb_a)$,
 $icoffa = \text{mod}(ja - 1, nb_a)$,
 $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,
 $mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol,$
 $NPCOL)$,
 $iroffc = \text{mod}(ic - 1, mb_c)$,
 $icoffc = \text{mod}(jc - 1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$,
 $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$,

```

mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by p_xerbla.

```

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(c)$, or $Q'^* \text{sub}(c)$, or $\text{sub}(c) * Q'$, or $\text{sub}(c) * Q$
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?geqlf

Computes the QL factorization of a general matrix.

Syntax

```

call psgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)

```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine forms the QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*L$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psgeqlf DOUBLE PRECISION for pdgeqlf COMPLEX for pcgeqlf DOUBLE COMPLEX for pzgeqlf Pointer into the local memory to an array of local dimension $(lld_a, LOCC(ja+n-1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A((ia:ia+m-1, ia:ia+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psgeqlf DOUBLE PRECISION for pdgeqlf COMPLEX for pcgeqlf DOUBLE COMPLEX for pzgeqlf Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb_a * (mp0 + nq0 + nb_a)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,

`iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),`
`mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),`
`nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL)`
`numroc` and `indxg2p` are ScaLAPACK tool functions; `MYROW`,
`MYCOL`, `NPROW` and `NPCOL` can be determined by calling the
subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local) REAL for <code>psgeqlf</code> DOUBLE PRECISION for <code>pdgeqlf</code> COMPLEX for <code>pcgeqlf</code> DOUBLE COMPLEX for <code>pzgeqlf</code> Array, DIMENSION <code>LOCc(ja+n-1)</code> . Contains the scalar factors of elementary reflectors. <code>tau</code> is tied to the distributed matrix A .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful.

< 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja),$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(m-k+i-1)$ is stored on exit in $A(ia+ia+m-k+i-2, ja+n-k+i-1)$, and τ in $\tau(ja+n-k+i-1)$.

p?orgql

Generates the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
call psorgql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by p?geqlf.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for psorgql DOUBLE PRECISION for pdorgql Pointer into the local memory to an array of local dimension ($lld_a, LOCC(ja+n-1)$). On entry, the j -th column must contain the vector which defines the elementary reflector $H(j), ja+n-k \leq j \leq ja+n-1$, as returned by p?geqlf in the k columns of its distributed matrix argument $A(ia:ja+n-k:ja+n-1)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A((ia:ia+m-1, ja:ja+n-1))$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .
<i>tau</i>	(local) REAL for psorgql DOUBLE PRECISION for pdorgql Array, DIMENSION $LOCC(ja+n-1)$. Contains the scalar factors $\tau(j)$ of elementary reflectors $H(j)$. τ is tied to the distributed matrix A .
<i>work</i>	(local) REAL for psorgql DOUBLE PRECISION for pdorgql Workspace array of dimension of $lwork$.
<i>lwork</i>	(local or global) INTEGER, dimension of $work$, must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a)$,

```

icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol,
NPCOL)
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> to be factored.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i*100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = -i.

p?ungql

Generates the unitary matrix Q of the QL factorization formed by p?geqlf.

Syntax

```

call pcungql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)

```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first n columns of a product of k elementary reflectors of order m

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by `p?geqlf`.

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) COMPLEX for <code>pcungql</code> DOUBLE COMPLEX for <code>pzungql</code> Pointer into the local memory to an array of local dimension $(lld_a, LOcc(ja+n-1))$. On entry, the j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by <code>p?geqlf</code> in the k columns of its distributed matrix argument $A(ia:*, ja+n-k: ja+n-1)$.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .
τ	(local) COMPLEX for <code>pcungql</code> DOUBLE COMPLEX for <code>pzungql</code> Array, DIMENSION $LOCr(ia+n-1)$. Contains the scalar factors $\tau(j)$ of elementary reflectors $H(j)$. τ is tied to the distributed matrix A .

<i>work</i>	<p>(local)</p> <p>COMPLEX for pcungql</p> <p>DOUBLE COMPLEX for pzungql</p> <p>Workspace array of dimension of <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER, dimension of <i>work</i>, must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where</p> <p>$iroffa = \text{mod}(ia-1, mb_a)$,</p> <p>$icoffa = \text{mod}(ja-1, nb_a)$,</p> <p>$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,</p> <p>$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,</p> <p>$mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW)$,</p> <p>$nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$</p> <p>$\text{indxg2p}$ and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <code>blacs_gridinfo</code>.</p> <p>If $lwork = -1$, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code>.</p>

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> to be factored.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	<p>(global) INTEGER.</p> <p>= 0: the execution is successful.</p> <p>< 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then $info = - (i * 100 + j)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then $info = -i$.</p>

p?ormql

Multiplies a general matrix by the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
call psormql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in mkl_scalapack.h file.

This routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C$ ($ic:ic+m-1, jc:jc+n-1$) with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$Q = H(k) \dots H(2) H(1)$

as returned by p?geqlf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^T is applied from the left. $= 'R'$: Q or Q^T is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'T'$, transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).

<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <i>sub(C)</i> ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psormql DOUBLE PRECISION for pdormql. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja+k-1</i>)). The <i>j</i> -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqlf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', $lld_a \geq \max(1, LOCr(ia+m-1))$, If <i>side</i> = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormql DOUBLE PRECISION for pdormql. Array, DIMENSION <i>LOCc</i> (<i>ja+n-1</i>)). Contains the scalar factor <i>tau</i> (<i>j</i>) of elementary reflectors $H(j)$ as returned by p?geqlf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psormql DOUBLE PRECISION for pdormql. Pointer into the local memory to an array of local dimension (<i>lld_c</i> , <i>LOCc</i> (<i>jc+n-1</i>)).

Contains the local pieces of the distributed matrix sub(*c*) to be factored.

ic, jc (global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix *c*, respectively.

descc (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *c*.

work (local)
 REAL for psormql
 DOUBLE PRECISION for pdormql.
 Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least:
 If *side* = 'L',
 $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a + nb_a * nb_a)$
 else if *side* = 'R',
 $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max npa0) + \text{numroc}(\text{numroc}(n + iroffa, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a + nb_a * nb_a)$
 end if
 where
 $lcmp = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(ia - 1, mb_a)$,
 $icoffa = \text{mod}(ja - 1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,
 $npa0 = \text{numroc}(n + iroffa, mb_a, MYROW, iarow, NPROW)$,
 $iroffc = \text{mod}(ic - 1, mb_c)$,
 $icoffc = \text{mod}(jc - 1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$,
 $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$,
 $mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$,
 $nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$,

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.
 If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info</code> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = - <i>i</i> .

p?unmql

Multiplies a general matrix by the unitary matrix Q of the Q_L factorization formed by p?geqlf.

Syntax

```
call pcunmql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunmql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine overwrites the general complex *m*-by-*n* distributed matrix `sub(C) = C` (`ic:ic+m-1, jc:jc+n-1`) with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(c)$	$sub(c) * Q$
$trans = 'C':$	$Q^H * sub(c)$	$sub(c) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by `p?geqlf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER
 $= 'L'$: Q or Q^H is applied from the left.
 $= 'R'$: Q or Q^H is applied from the right.

trans (global) CHARACTER
 $= 'N'$, no transpose, Q is applied.
 $= 'C'$, conjugate transpose, Q^H is applied.

m (global) INTEGER. The number of rows in the distributed matrix $sub(c)$ ($m \geq 0$).

n (global) INTEGER. The number of columns in the distributed matrix $sub(c)$ ($n \geq 0$).

k (global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:
If $side = 'L'$, $m \geq k \geq 0$
If $side = 'R'$, $n \geq k \geq 0$.

a (local)
COMPLEX for `pcunmql`
DOUBLE COMPLEX for `pzunmql`.
Pointer into the local memory to an array of dimension $(lld_a, LOcc(ja+k-1))$. The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by `p?geqlf` in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.
If $side = 'L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$,

	If <i>side</i> = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmql DOUBLE COMPLEX for pzunmql Array, DIMENSION $LOCc(ia+n-1)$. Contains the scalar factor <i>tau</i> (<i>j</i>) of elementary reflectors $H(j)$ as returned by p?geqlf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for pcunmql DOUBLE COMPLEX for pzunmql. Pointer into the local memory to an array of local dimension ($lld_c, LOCc(jc+n-1)$). Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) COMPLEX for pcunmql DOUBLE COMPLEX for pzunmql. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a + nb_a * nb_a)$ else if <i>side</i> = 'R',

```

lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0+max npa0)+
numroc(numroc(n+icoffc, nb_a, 0, 0, NPCOL),
nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a
end if

```

where

```

lcmp = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc (n + iroffa, mb_a, MYROW, iarow,
NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),

```

ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(c)$, or $Q' \text{sub}(c)$, or $\text{sub}(c)^* Q'$, or $\text{sub}(c)^* Q$
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful.

< 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?gerqf

Computes the RQ factorization of a general rectangular matrix.

Syntax

```
call psgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = R * Q$$

Input Parameters

m	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; ($n \geq 0$).
a	(local) REAL for psgeqrf DOUBLE PRECISION for pdgeqrf COMPLEX for pcgeqrf DOUBLE COMPLEX for pzgeqrf. Pointer into the local memory to an array of local dimension ($lld_a, LOCC(ja+n-1)$).

	Contains the local pieces of the distributed matrix sub(<i>A</i>) to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>
<i>work</i>	(local). REAL for psgeqrf DOUBLE PRECISION for pdgeqrf. COMPLEX for pcgeqrf. DOUBLE COMPLEX for pzgeqrf Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mp0 = \text{numroc}(m+iroff, mb_a, MYROW, iarow, NPROW)$, $nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL)$ and <code>numroc</code> , <code>indxg2p</code> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <code>blacs_gridinfo</code> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>p_xerbla</code> .

Output Parameters

<i>a</i>	On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix <i>R</i> ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix <i>R</i> ; the remaining
----------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	elements, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) REAL for psgeqrf DOUBLE PRECISION for pdgeqrf COMPLEX for pcgeqrf DOUBLE COMPLEX for pzgeqrf. Array, DIMENSION <i>LOCr</i> (<i>ia+m-1</i>). Contains the scalar factor <i>tau</i> of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0, the execution is successful. < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1) / \text{conjg}(v(1:n-k+i-1))$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in $\tau(ia+m-k+i-1)$.

p?orgrq

Generates the orthogonal matrix Q of the RQ factorization formed by p?gerqf.

Syntax

```
call psorgrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last m rows of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by p?gerqf.

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq m \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) REAL for psorgrq DOUBLE PRECISION for pdorgrq Pointer into the local memory to an array of local dimension $(lld_a, LOCC(ja+n-1))$. The i -th column must contain the vector which defines the elementary reflector $H(i)$, $ja \leq j \leq ja+k-1$, as returned by p?gerqf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psorgqr DOUBLE PRECISION for pdorgqr Array, DIMENSION <i>LOCc(ja+k-1)</i> . Contains the scalar factor <i>tau(i)</i> of elementary reflectors $H(i)$ as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psorgqr DOUBLE PRECISION for pdorgqr Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>p?xerbla</i> .

Output Parameters

<i>a</i>	Contains the local pieces of the m -by- n distributed matrix Q .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ungrq

Generates the unitary matrix Q of the RQ factorization formed by p?gerqf.

Syntax

```
call pcungrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine generates the m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = (H(1))^H \star (H(2))^H \star \dots \star (H(k))^H$ as returned by p?gerqf.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq m \geq 0$).

<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrqc Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. The i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by p?gerqf in the k rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrq Array, DIMENSION $LOCr(ia+m-1)$. Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrq Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q .
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info</code> = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ormrq

Multiplies a general matrix by the orthogonal matrix Q of the RQ factorization formed by `p?gerqf`.

Syntax

```
call psormrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine overwrites the general real m -by- n distributed matrix `sub(C) = C(ic:ic+m-1, jc:jc+n-1)` with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(c)$	$sub(c) * Q$
$trans = 'T':$	$Q^T * sub(c)$	$sub(c) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?gerqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^T is applied from the left. $= 'R'$: Q or Q^T is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'T'$, transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $sub(c)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $sub(c)$ ($n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
a	(local) REAL for <code>psormqr</code> DOUBLE PRECISION for <code>pdormqr</code> . Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+m-1))$ if $side = 'L'$, and $(lld_a, LOCC(ja+n-1))$ if $side = 'R'$. The i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr Array, DIMENSION <i>LOCc(ja+k-1)</i> . Contains the scalar factor <i>tau(i)</i> of elementary reflectors <i>H(i)</i> as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psormrq DOUBLE PRECISION for pdormrq Pointer into the local memory to an array of local dimension (<i>lld_c, LOCc(jc+n-1)</i>). Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psormrq DOUBLE PRECISION for pdormrq. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0))*mb_a) + mb_a*mb_a$ else if <i>side</i> = 'R',

```

lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 +
nqc0)*mb_a) + mb_a*mb_a
end if
where
lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol,
NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by p_xerbla.

```

Output Parameters

<i>c</i>	Overwritten by the product $Q * \text{sub}(c)$, or $Q' * \text{sub}(c)$, or $\text{sub}(c) * Q'$, or $\text{sub}(c) * Q$
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmrq

Multiplies a general matrix by the unitary matrix Q of the RQ factorization formed by p?gerqf.

Syntax

```
call pcunmrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pzunmrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine overwrites the general complex m -by- n distributed matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by p?gerqf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$ (global) CHARACTER
 $= 'L'$: Q or Q^H is applied from the left.
 $= 'R'$: Q or Q^H is applied from the right.

$trans$ (global) CHARACTER
 $= 'N'$, no transpose, Q is applied.

	= 'C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix <code>sub(c)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <code>sub(c)</code> ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmrq DOUBLE COMPLEX for pzunmrq. Pointer into the local memory to an array of dimension $(lld_a, LOCc(ja+m-1))$ if <i>side</i> = 'L', and $(lld_a, LOCc(ja+n-1))$ if <i>side</i> = 'R'. The <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gerqf</code> in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja^*)$. $A(ia:ia+k-1, ja^*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmrq DOUBLE COMPLEX for pzunmrq Array, DIMENSION $LOCc(ja+k-1)$. Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by <code>p?gerqf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for pcunmrq DOUBLE COMPLEX for pzunmrq.

	<p>Pointer into the local memory to an array of local dimension $(lld_c, LOCC(jc+n-1))$. Contains the local pieces of the distributed matrix sub(c) to be factored.</p>
ic, jc	<p>(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix c, respectively.</p>
$descc$	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix c.</p>
$work$	<p>(local) COMPLEX for pcunmrq DOUBLE COMPLEX for pzunmrq. Workspace array of dimension of $lwork$.</p>
$lwork$	<p>(local or global) INTEGER, dimension of $work$, must be at least: If $side = 'L'$, $lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0 +$ $\max(mqa0+numroc(numroc(n+iroffc, mb_a, 0, 0,$ $NPROW), mb_a, 0, 0, lcmp), nqc0))*mb_a) +$ mb_a*mb_a else if $side = 'R'$, $lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0 +$ $nqc0)*mb_a) + mb_a*mb_a$ end if where $lcmp = lcm/NPROW$ with $lcm = ilcm(NPROW, NPCOL)$, $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mqa0 = \text{numroc}(m+icoffa, nb_a, MYCOL, iacol,$ $NPCOL)$, $iroffc = \text{mod}(ic-1, mb_c)$, $icoffc = \text{mod}(jc-1, nb_c)$, $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$, $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$, $mpc0 = \text{numroc}(m+iroffc, mb_c, MYROW, icrow,$ $NPROW)$, </p>

`nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),`
`ilcm, indxg2p` and `numroc` are ScaLAPACK tool functions;
`MYROW, MYCOL, NPROW` and `NPCOL` can be determined by
calling the subroutine `blacs_gridinfo`.
If `lwork = -1`, then `lwork` is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by `pzerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q^* \text{sub}(c)$ or $Q'^* \text{sub}(c)$, or $\text{sub}(c)^* Q'$, or $\text{sub}(c)^* Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?tzrzf

Reduces the upper trapezoidal matrix A to upper triangular form.

Syntax

```
call pstzrzf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdtzrzf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pctzrzf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pztzrzf( m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = (ia:ia+m-1, ja:ja+n-1)$ to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as

$$A = (R \ 0) * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(A)$; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for <code>pstzrzf</code> DOUBLE PRECISION for <code>pdtzrzf</code> . COMPLEX for <code>pctzrzf</code> . DOUBLE COMPLEX for <code>pztzrzf</code> . Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. Contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <code>pstzrzf</code> DOUBLE PRECISION for <code>pdtzrzf</code> . COMPLEX for <code>pctzrzf</code> . DOUBLE COMPLEX for <code>pztzrzf</code> . Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$,

```

iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc (m+iroff, mb_a, MYROW, iarow,
NPROW),
nq0 = numroc (n+icoff, nb_a, MYCOL, iacol,
NPCOL)

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, the leading <i>m</i> -by- <i>m</i> upper triangular part of <code>sub(A)</code> contains the upper triangular matrix <i>R</i> , and elements <i>m</i> +1 to <i>n</i> of the first <i>m</i> rows of <code>sub (A)</code> , with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Z</i> as a product of <i>m</i> elementary reflectors.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>tau</i>	(local) REAL for <code>pstzrzf</code> DOUBLE PRECISION for <code>pdtzrzf</code> . COMPLEX for <code>pctzrzf</code> . DOUBLE COMPLEX for <code>pztzrzf</code> . Array, DIMENSION <code>LOCr(ia+m-1)</code> . Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The factorization is obtained by the Householder's method. The k -th transformation matrix, $Z(k)$, which is or whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ -th row of $\text{sub}(A)$, is given in the form

$$Z(k) = \begin{bmatrix} i & 0 \\ 0 & T(k) \end{bmatrix}$$

where

$$T(k) = i - \tau u(k) u(k)^T,$$

$$u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $Z(k)$ is an $(n - m)$ element vector. τ and $Z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $Z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$. Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

p?ormrz

Multiplies a general matrix by the orthogonal matrix from a reduction to upper triangular form formed by p?tzzrf.

Syntax

```
call psormrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?tzrzf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER ='L': Q or Q^T is applied from the left. ='R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER ='N', no transpose, Q is applied. ='T', transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
<i>l</i>	(global) The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If $side = 'L'$, $m \geq l \geq 0$ If $side = 'R'$, $n \geq l \geq 0$.

<i>a</i>	<p>(local)</p> <p>REAL for psormrz DOUBLE PRECISION for pdormrz.</p> <p>Pointer into the local memory to an array of dimension $(lld_a, LOCc(ja+m-1))$ if <i>side</i> = 'L', and $(lld_a, LOCc(ja+n-1))$ if <i>side</i> = 'R', where $lld_a \geq \max(1, LOCr(ia+k-1))$.</p> <p>The <i>i</i>-th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?tzrzf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _—). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	<p>(local)</p> <p>REAL for psormrz DOUBLE PRECISION for pdormrz</p> <p>Array, DIMENSION $LOCc(ia+k-1)$.</p> <p>Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by p?tzrzf. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local)</p> <p>REAL for psormrz DOUBLE PRECISION for pdormrz</p> <p>Pointer into the local memory to an array of local dimension $(lld_c, LOCc(jc+n-1))$.</p> <p>Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.</p>
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>desc</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _—). The array descriptor for the distributed matrix <i>C</i> .

work (local)
 REAL for psormrz
 DOUBLE PRECISION for pdormrz.
 Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least:
 If *side* = 'L',
 $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcm), nqc0)) * mb_a) + mb_a * mb_a)$
 else if *side* = 'R',
 $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a) + mb_a * mb_a$
 end if
 where
 $lcm = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(ia - 1, mb_a)$, $icoffa = \text{mod}(ja - 1, nb_a)$,
 $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,
 $mqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$,
 $iroffc = \text{mod}(ic - 1, mb_c)$,
 $icoffc = \text{mod}(jc - 1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$,
 $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$,
 $mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$,
 $nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$,
 $ilcm, \text{indxg2p}$ and numroc are ScaLAPACK tool functions;
 $MYROW, MYCOL, NPROW$ and $NPCOL$ can be determined by calling the subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q*\text{sub}(c)$, or $Q'^*\text{sub}(c)$, or $\text{sub}(c)*Q$, or $\text{sub}(c)*Q'$, or $\text{sub}(c)*Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

p?unmrz

Multiplies a general matrix by the unitary transformation matrix from a reduction to upper triangular form determined by p?tzrzf.

Syntax

```
call pcunmrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunmrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q*\text{sub}(c)$	$\text{sub}(c)*Q$
$trans = 'C':$	$Q^H*\text{sub}(c)$	$\text{sub}(c)*Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by `pctzrzf/pztzrzf`. Q is of order m if `side = 'L'` and of order n if `side = 'R'`.

Input Parameters

<code>side</code>	(global) CHARACTER ='L': Q or Q^H is applied from the left. ='R': Q or Q^H is applied from the right.
<code>trans</code>	(global) CHARACTER ='N', no transpose, Q is applied. ='C', conjugate transpose, Q^H is applied.
<code>m</code>	(global) INTEGER. The number of rows in the distributed matrix <code>sub(c)</code> , ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the distributed matrix <code>sub(c)</code> , ($n \geq 0$).
<code>k</code>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <code>side = 'L'</code> , $m \geq k \geq 0$ If <code>side = 'R'</code> , $n \geq k \geq 0$.

MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by p_xerbla.

```

Output Parameters

<i>c</i>	Overwritten by the product $Q * \text{sub}(c)$, or $Q' * \text{sub}(c)$, or $\text{sub}(c) * Q'$, or $\text{sub}(c) * Q$
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ggqrf

Computes the generalized QR factorization.

Syntax

```
call psggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

```
call pdggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

```
call pcggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

```
call pzggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine forms the generalized QR factorization of an n -by- m matrix

$$\text{sub}(A) = A(ia:ia+n-1, ja:ja+m-1)$$

and an n -by- p matrix

$$\text{sub}(B) = B(ib:ib+n-1, jb:jb+p-1):$$

as

$$\text{sub}(A) = Q^*R, \text{ sub}(B) = Q^*T^*Z,$$

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

If $n \geq m$

$$R = \begin{pmatrix} R_{11} & \\ & 0 \end{pmatrix} \begin{matrix} m \\ n - m \\ m \end{matrix}$$

or if $n < m$

$$R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} n \\ m - n \end{matrix}$$

where R_{11} is upper triangular, and

$$T = \begin{pmatrix} 0 & T_{12} \\ T_{21} & 0 \end{pmatrix} \begin{matrix} n, \text{ if } n \leq p, \\ p - n \end{matrix}$$

$$\text{or } T = \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \begin{pmatrix} n - p \\ p \end{pmatrix}, \text{ if } n > p,$$

where T_{12} or T_{21} is an upper triangular matrix.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GQR factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the QR factorization of $\text{inv}(\text{sub}(B)) * \text{sub}(A)$:

$$\text{inv}(\text{sub}(B)) * \text{sub}(A) = Z^H * (\text{inv}(T) * R$$

Input Parameters

n	(global) INTEGER. The number of rows in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
m	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).

<i>p</i>	INTEGER. The number of columns in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).
<i>a</i>	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+m-1))$. Contains the local pieces of the n -by- m matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Pointer into the local memory to an array of dimension $(lld_b, LOCC(jb+p-1))$. Contains the local pieces of the n -by- p matrix $\text{sub}(B)$ to be factored.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Dimension of <i>work</i> , must be at least

```

lwork ≥ max(nb_a*(npa0+mqa0+nb_a),
max((nb_a*(nb_a-1))/2,
(pqb0+npb0)*nb_a)+nb_a*nb_a,
mb_b*(npb0+pqb0+mb_b)),
where
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
npa0 = numroc (n+iroffa, mb_a, MYROW, iarow,
NPROW),
mqa0 = numroc (m+icoffa, nb_a, MYCOL, iacol,
NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
npb0 = numroc (n+iroffa, mb_b, MYROW, Ibrow,
NPROW),
pqb0 = numroc(m+icoffb, nb_b, MYCOL, ibcol,
NPCOL)

```

and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, the elements on and above the diagonal of sub (*A*) contain the min(*n*, *m*)-by-*m* upper trapezoidal matrix *R* (*R* is upper triangular if *n* ≥ *m*); the elements below the diagonal, with the array *taua*, represent the orthogonal/unitary matrix *Q* as a product of min(*n*, *m*) elementary reflectors. (See Application Notes below).

<i>taua, taub</i>	<p>(local)</p> <p>REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf.</p> <p>Arrays, DIMENSION $LOCc(ja+\min(n,m)-1)$ for <i>taua</i> and $LOCr(ib+n-1)$ for <i>taub</i>.</p> <p>The array <i>taua</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q. <i>taua</i> is tied to the distributed matrix <i>A</i>. (See Application Notes below).</p> <p>The array <i>taub</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z. <i>taub</i> is tied to the distributed matrix <i>B</i>. (See Application Notes below).</p>
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	<p>(global) INTEGER.</p> <p>= 0: the execution is successful.</p> <p>< 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then $info = -(i*100+j)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then $info = -i$.</p>

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1),$$

where $k = \min(n, m)$.

Each $H(i)$ has the form

$$H(i) = I - \tau u u^*$$

where τ is a real/complex scalar, and u is a real/complex vector with $u(1:i-1) = 0$ and $u(i) = 1$; $u(i+1:n)$ is stored on exit in $A(ia+i:ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$. To form Q explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Q to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

The matrix Z is represented as a product of elementary reflectors

$Z = H(ib) * H(ib+1) * \dots * H(ib+k-1)$, where $k = \min(n, p)$.

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(ib+n-k+i-1, jb:jb+p-k+i-2)$, and τ in $\tau(ib+n-k+i-1)$. To form Z explicitly, use ScaLAPACK subroutine [p?orgrq/p?ungrq](#). To use Z to update another matrix, use ScaLAPACK subroutine [p?ormrq/p?unmrq](#).

p?ggrqf

Computes the generalized RQ factorization.

Syntax

```
call psggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

```
call pdggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

```
call pcggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

```
call pzggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
            lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine forms the generalized RQ factorization of an m -by- n matrix $\text{sub}(A) = (ia:ia+m-1, ja:ja+n-1)$ and a p -by- n matrix $\text{sub}(B) = (ib:ib+p-1, ja:ja+n-1)$:

$$\text{sub}(A) = R^* Q, \quad \text{sub}(B) = Z^* T^* Q,$$

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{pmatrix} m & 0 & R_{12} \\ n-m & m & m \end{pmatrix}, \text{ if } m \leq n,$$

or

$$R = \begin{pmatrix} R_{11} & \\ & R_{12} \end{pmatrix} \begin{matrix} m - n \\ n \\ n \end{matrix}, \text{ if } m > n$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{pmatrix} T_{11} & \\ 0 & \end{pmatrix} \begin{matrix} n \\ p - n \\ n \end{matrix}, \text{ if } p \geq n$$

or

$$T = \begin{pmatrix} T_{11} & T_{12} \\ & \end{pmatrix} \begin{matrix} p \\ n - p \end{matrix}, \text{ if } p < n,$$

where T^{11} is upper triangular.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GRQ factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the RQ factorization of $\text{sub}(A) * \text{inv}(\text{sub}(B))$:

$$\text{sub}(A) * \text{inv}(\text{sub}(B)) = (R * \text{inv}(T)) * Z'$$

where $\text{inv}(\text{sub}(B))$ denotes the inverse of the matrix $\text{sub}(B)$, and Z' denotes the transpose (conjugate transpose) of matrix Z .

Input Parameters

- m (global) INTEGER. The number of rows in the distributed matrices $\text{sub}(A)$ ($m \geq 0$).
- p INTEGER. The number of rows in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).

<i>n</i>	(global) INTEGER. The number of columns in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. Contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of dimension $(lld_b, LOCC(jb+n-1))$. Contains the local pieces of the p -by- n matrix $\text{sub}(B)$ to be factored.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER.

Dimension of *work*, must be at least $lwork \geq$

```

max(mb_a*(mpa0+nqa0+mb_a),
max((mb_a*(mb_a-1))/2, (ppb0+nqb0)*mb_a) +
mb_a*mb_a, nb_b*(ppb0+nqb0+nb_b)), where
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc (m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc (m+icoffa, nb_a, MYCOL, iacol,
NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW
),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL
),
ppb0 = numroc (p+iroffb, mb_b, MYROW, ibrow,
NPROW),
nqb0 = numroc (n+icoffb, nb_b, MYCOL, ibcol,
NPCOL)

```

and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ;

taua, taub

the remaining elements, with the array *tauu*, represent the orthogonal/unitary matrix *Q* as a product of $\min(n, m)$ elementary reflectors (see *Application Notes* below).

(local)

REAL for psggqrf

DOUBLE PRECISION for pdggqrf

COMPLEX for pcggqrf

DOUBLE COMPLEX for pzggqrf.

Arrays, DIMENSION $LOCr(ia+m-1)$ for $taua$ and

$$LOCc(jb+\min(p,n)-1) \text{ for } taub.$$

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*. *taua* is tied to the distributed matrix *A*. (See *Application Notes* below).

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*. *taub* is tied to the distributed matrix *B*. (See *Application Notes* below).

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

`< 0`: if the i -th argument is an array and the j -entry had an illegal value, then `info` = $-(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then `info` = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = i - \tau a^* v^* v'$$

where τ_{aua} is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ_{aua} in $\tau_{aua}(ia+m-k+i-1)$. To form Q explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungrq](#). To use Q to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

The matrix Z is represented as a product of elementary reflectors

$$Z = H(jb) * H(jb+1) * \dots * H(jb+k-1), \text{ where } k = \min(p, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{aub} * v * v'$$

where τ_{aub} is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(ib+i:ib+p-1, jb+i-1)$, and τ_{aub} in $\tau_{aub}(jb+i-1)$. To form Z explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Z to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

Symmetric Eigenproblems

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form T and then find the eigenvalues and eigenvectors of the tridiagonal matrix T . ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table 6-4](#).

There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the QTQ algorithm, or bisection followed by inverse iteration).

Table 6-4 Computational Routines for Solving Symmetric Eigenproblems

Operation	Dense symmetric/Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Reduce to tridiagonal form $A = QTQ^H$	p?sytrd/p?hetrd		
Multiply matrix after reduction		p?ormtr/p?unmtr	
Find all eigenvalues and eigenvectors of a tridiagonal matrix T by a QTQ method			steqr2 *)
Find selected eigenvalues of a tridiagonal matrix T via bisection			p?stebz

Operation	Dense symmetric/Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Find selected eigenvectors of a tridiagonal matrix T by inverse iteration			p?stein

*) This routine is described as part of auxiliary ScaLAPACK routines.

p?sytrd

Reduces a symmetric matrix to real symmetric tridiagonal form by an orthogonal similarity transformation.

Syntax

```
call pssytrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine reduces a real symmetric matrix `sub(A)` to symmetric tridiagonal form T by an orthogonal similarity transformation:

$$Q'^* \text{sub}(A) Q = T,$$

where `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix <code>sub(A)</code> is stored: If <code>uplo = 'U'</code> , upper triangular If <code>uplo = 'L'</code> , lower triangular
<code>n</code>	(global) INTEGER. The order of the distributed matrix <code>sub(A)</code> ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pssytrd</code> DOUBLE PRECISION for <code>pdsytrd</code> .

	<p>Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the symmetric distributed matrix $\text{sub}(A)$. If $uplo = 'U'$, the leading n-by-n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n-by-n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See <i>Application Notes</i> below.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	<p>(local)</p> <p>REAL for pssytrd</p> <p>DOUBLE PRECISION for pdsytrd.</p> <p>Workspace array of dimension <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER, dimension of <i>work</i>, must be at least:</p> $lwork \geq \max(NB*(np + 1), 3*NB),$ <p>where $NB = mb_a = nb_a$,</p> $np = \text{numroc}(n, NB, MYROW, iarow, NPROW),$ $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW).$ <p><code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <code>blacs_gridinfo</code>.</p> <p>If $lwork = -1$, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>p_xerbla</code>.</p>

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors. See <i>Application Notes</i> below.
<i>d</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Arrays, DIMENSION <i>LOCc</i> (<i>ja+n-1</i>) .The diagonal elements of the tridiagonal matrix <i>T</i> : $d(i) = A(i, i)$. <i>d</i> is tied to the distributed matrix <i>A</i> .
<i>e</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Arrays, DIMENSION <i>LOCc</i> (<i>ja+n-1</i>) if <i>uplo</i> = 'U', <i>LOCc</i> (<i>ja+n-2</i>) otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i> : $e(i) = A(i, i+1)$ if <i>uplo</i> = 'U', $e(i) = A(i+1, i)$ if <i>uplo</i> = 'L'. <i>e</i> is tied to the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Arrays, DIMENSION <i>LOCc</i> (<i>ja+n-1</i>) . This array contains the scalar factors <i>tau</i> of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v',$$

where *tau* is a real scalar, and *v* is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and *tau* in $\tau(ja+i-1)$.

If *uplo* = 'L', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v',$$

where *tau* is a real scalar, and *v* is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and *tau* in $\tau(ja+i-1)$.

The contents of sub(*A*) on exit are illustrated by the following examples with *n* = 5:

If *uplo* = 'U':

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If *uplo* = 'L':

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

p?ormtr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?sytrd.

Syntax

```
call psormtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine overwrites the general real distributed m -by- n matrix `sub(C)` = `C(ic:ic+m-1, jc:jc+n-1)` with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	<code>Q*sub(c)</code>	<code>sub(c)*Q</code>
<code>trans = 'T':</code>	<code>Q^T*sub(c)</code>	<code>sub(c)*Q^T</code>

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if `side = 'L'` and $nq = n$ if `side = 'R'`.

Q is defined as the product of nq elementary reflectors, as returned by `p?sytrd`.

If `uplo = 'U'`, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>uplo</i>	(global) CHARACTER. = 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?sytrd; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?sytrd
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub(<i>c</i>) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(<i>c</i>) ($n \geq 0$).
<i>a</i>	(local) REAL for psormtr DOUBLE PRECISION for pdormtr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+m-1)</i>) if <i>side</i> ='L', or (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>) if <i>side</i> = 'R'. Contains the vectors which define the elementary reflectors, as returned by p?sytrd. If <i>side</i> ='L', $lld_a \geq \max(1, LOCr(ia+m-1))$; If <i>side</i> = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormtr

	<p>DOUBLE PRECISION for <code>pdormtr</code>. Array, DIMENSION of <code>ltau</code> where if <code>side = 'L'</code> and <code>uplo = 'U'</code>, <code>ltau = LOcc(m_a)</code>, if <code>side = 'L'</code> and <code>uplo = 'L'</code>, <code>ltau = LOcc(ja+m-2)</code>, if <code>side = 'R'</code> and <code>uplo = 'U'</code>, <code>ltau = LOcc(n_a)</code>, if <code>side = 'R'</code> and <code>uplo = 'L'</code>, <code>ltau = LOcc(ja+n-2)</code>. <code>tau(i)</code> must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>p?sytrd</code>. <code>tau</code> is tied to the distributed matrix <code>A</code>.</p>
<code>c</code>	<p>(local) REAL for <code>psormtr</code> DOUBLE PRECISION for <code>pdormtr</code>. Pointer into the local memory to an array of dimension <code>(lld_a, LOcc(ja+n-1))</code>. Contains the local pieces of the distributed matrix sub (<code>c</code>).</p>
<code>ic, jc</code>	<p>(global) INTEGER. The row and column indices in the global array <code>c</code> indicating the first row and the first column of the submatrix <code>C</code>, respectively.</p>
<code>descc</code>	<p>(global and local) INTEGER array, dimension <code>(dlen_)</code>. The array descriptor for the distributed matrix <code>C</code>.</p>
<code>work</code>	<p>(local) REAL for <code>psormtr</code> DOUBLE PRECISION for <code>pdormtr</code>. Workspace array of dimension <code>lwork</code>.</p>
<code>lwork</code>	<p>(local or global) INTEGER, dimension of <code>work</code>, must be at least: if <code>uplo = 'U'</code>, <code>iaa= ia; jaa= ja+1, icc= ic; jcc= jc;</code> else <code>uplo = 'L'</code>, <code>iaa= ia+1, jaa= ja;</code> If <code>side = 'L'</code>, <code>icc= ic+1; jcc= jc;</code> else <code>icc= ic; jcc= jc+1;</code> end if end if If <code>side = 'L'</code>, <code>mi= m-1; ni= n</code></p>

MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo. If lwork = -1,
then lwork is global input and a workspace query is
assumed; the routine only calculates the minimum and
optimal size for all work arrays. Each of these values is
returned in the first entry of the corresponding work array,
and no error message is issued by pxxerbla.

```

Output Parameters

c

Overwritten by the product $Q \cdot \text{sub}(c)$, or $Q' \cdot \text{sub}(c)$, or $\text{sub}(c) \cdot Q'$, or $\text{sub}(c) \cdot Q$.

<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	<p>(global) INTEGER.</p> <p>= 0: the execution is successful.</p> <p>< 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <code>info</code> = - (<i>i</i>* 100+<i>j</i>), if the <i>i</i>-th argument is a scalar and had an illegal value, then <code>info</code> = -<i>i</i>.</p>

p?hetrd

Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.

Syntax

```
call pchetrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine reduces a complex Hermitian matrix `sub(A)` to Hermitian tridiagonal form *T* by a unitary similarity transformation:

$$Q'^* \text{sub}(A) * Q = T$$

where `sub(A)` = `A(ia:ia+n-1, ja:ja+n-1)`.

Input Parameters

<code>uplo</code>	<p>(global) CHARACTER.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix <code>sub(A)</code> is stored:</p> <p>If <code>uplo</code> = 'U', upper triangular</p> <p>If <code>uplo</code> = 'L', lower triangular</p>
<code>n</code>	<p>(global) INTEGER. The order of the distributed matrix <code>sub(A)</code> (<i>n</i> ≥ 0).</p>
<code>a</code>	(local)

COMPLEX for pchetrd
DOUBLE COMPLEX for pzhetrd.

Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the Hermitian distributed matrix $\text{sub}(A)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see *Application Notes* below).

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix *A*.

work (local)
COMPLEX for pchetrd
DOUBLE COMPLEX for pzhetrd.
Workspace array of dimension *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least:

$$lwork \geq \max(NB * (np + 1), 3 * NB)$$

where $NB = mb_a = nb_a$,
 $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$,
 $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW)$.
indxg2p and *numroc* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine *blacs_gridinfo*.
If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pzerbla*.

Output Parameters

<i>a</i>	<p>On exit,</p> <p>If <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i>, and the elements above the first superdiagonal, with the array <i>tau</i>, represent the unitary matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i>, and the elements below the first subdiagonal, with the array <i>tau</i>, represent the unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).</p>
<i>d</i>	<p>(local)</p> <p>REAL for pchetrd DOUBLE PRECISION for pzhetrd. Arrays, DIMENSION <i>LOCc</i>(<i>ja+n-1</i>). The diagonal elements of the tridiagonal matrix <i>T</i>: <i>d</i>(<i>i</i>) = <i>A</i>(<i>i</i>,<i>i</i>). <i>d</i> is tied to the distributed matrix <i>A</i>.</p>
<i>e</i>	<p>(local)</p> <p>REAL for pchetrd DOUBLE PRECISION for pzhetrd. Arrays, DIMENSION <i>LOCc</i>(<i>ja+n-1</i>) if <i>uplo</i> = 'U'; <i>LOCc</i>(<i>ja+n-2</i>) - otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i>: <i>e</i>(<i>i</i>) = <i>A</i>(<i>i</i>,<i>i+1</i>) if <i>uplo</i> = 'U', <i>e</i>(<i>i</i>) = <i>A</i>(<i>i+1</i>,<i>i</i>) if <i>uplo</i> = 'L'. <i>e</i> is tied to the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local) COMPLEX for pchetrd DOUBLE COMPLEX for pzhetrd. Arrays, DIMENSION <i>LOCc</i>(<i>ja+n-1</i>). This array contains the scalar factors <i>tau</i> of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>work</i> (1)	<p>On exit <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance.</p>
<i>info</i>	<p>(global) INTEGER.</p>

$= 0$: the execution is successful.
 < 0 : if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If $uplo = 'L'$:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

p?unmtr

Multiplies a general matrix by the unitary transformation matrix from a reduction to tridiagonal form determined by p?hetrd.

Syntax

```
call pcunmtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunmtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine overwrites the general complex distributed m -by- n matrix `sub(C)` = `C(ic:ic+m-1, jc:jc+n-1)` with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $nq-1$ elementary reflectors, as returned by [p?hetrd](#).

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

side (global) CHARACTER
 = 'L': Q or Q^H is applied from the left.
 = 'R': Q or Q^H is applied from the right.

trans (global) CHARACTER
 = 'N', no transpose, Q is applied.
 = 'C', conjugate transpose, Q^H is applied.

uplo (global) CHARACTER.
 = 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from $p?hetrd$;
 = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from $p?hetrd$

m (global) INTEGER. The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$).

n (global) INTEGER. The number of columns in the distributed matrix $sub(C)$ ($n \geq 0$).

a (local)
 REAL for $pcunmtr$
 DOUBLE PRECISION for $pzunmtr$.
 Pointer into the local memory to an array of dimension $(lld_a, LOCc(ja+m-1))$ if $side='L'$, or $(lld_a, LOCc(ja+n-1))$ if $side = 'R'$.
 Contains the vectors which define the elementary reflectors, as returned by $p?hetrd$.
 If $side='L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$;
 If $side = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$.

ia, ja (global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca (global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .

tau (local)
 COMPLEX for $pcunmtr$

	<p>DOUBLE COMPLEX for pzunmtr. Array, DIMENSION of <i>ltau</i> where If <i>side</i> = 'L' and <i>uplo</i> = 'U', <i>ltau</i> = <i>LOCc</i>(<i>m_a</i>), if <i>side</i> = 'L' and <i>uplo</i> = 'L', <i>ltau</i> = <i>LOCc</i>(<i>ja+m-2</i>), if <i>side</i> = 'R' and <i>uplo</i> = 'U', <i>ltau</i> = <i>LOCc</i>(<i>n_a</i>), if <i>side</i> = 'R' and <i>uplo</i> = 'L', <i>ltau</i> = <i>LOCc</i>(<i>ja+n-2</i>). <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by p?hetrd. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local) COMPLEX for pcunmtr DOUBLE COMPLEX for pzunmtr. Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc</i> (<i>ja+n-1</i>)). Contains the local pieces of the distributed matrix sub (<i>c</i>).</p>
<i>ic, jc</i>	<p>(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i>, respectively.</p>
<i>descc</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i>.</p>
<i>work</i>	<p>(local) COMPLEX for pcunmtr DOUBLE COMPLEX for pzunmtr. Workspace array of dimension <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER, dimension of <i>work</i>, must be at least: If <i>uplo</i> = 'U', <i>iaa</i>= <i>ia</i>; <i>jaa</i>= <i>ja+1</i>, <i>icc</i>= <i>ic</i>; <i>jcc</i>= <i>jc</i>; else <i>uplo</i> = 'L', <i>iaa</i>= <i>ia+1</i>, <i>jaa</i>= <i>ja</i>; If <i>side</i> = 'L', <i>icc</i>= <i>ic+1</i>; <i>jcc</i>= <i>jc</i>; else <i>icc</i>= <i>ic</i>; <i>jcc</i>= <i>jc+1</i>; end if end if If <i>side</i> = 'L', <i>mi</i>= <i>m-1</i>; <i>ni</i>= <i>n</i></p>

```

lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
mpc0)*nb_a) + nb_a*nb_a
else
If side = 'R',

ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo. If lwork = -1,
then lwork is global input and a workspace query is
assumed; the routine only calculates the minimum and
optimal size for all work arrays. Each of these values is
returned in the first entry of the corresponding work array,
and no error message is issued by pxxerbla.

```

Output Parameters

c

Overwritten by the product $Q^* \text{sub}(c)$, or $Q' * \text{sub}(c)$, or $\text{sub}(c) * Q'$, or $\text{sub}(c) * Q$.

<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = - i</code>

p?stebz

Computes the eigenvalues of a symmetric tridiagonal matrix by bisection.

Syntax

```
call psstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit,
w, iblock, isplit, work, iwork, liwork, info)

call pdstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit,
w, iblock, isplit, work, iwork, liwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval `[vl vu]`, or the eigenvalues indexed `il` through `iu`. A static partitioning of work is done at the beginning of `p?stebz` which results in all processes finding an (almost) equal number of eigenvalues.

Input Parameters

<code>ictxt</code>	(global) INTEGER. The BLACS context handle.
<code>range</code>	(global) CHARACTER. Must be 'A' or 'V' or 'I'. If <code>range = 'A'</code> , the routine computes all eigenvalues. If <code>range = 'V'</code> , the routine computes eigenvalues in the interval <code>[vl, vu]</code> . If <code>range = 'I'</code> , the routine computes eigenvalues with indices <code>il</code> to <code>iu</code> .
<code>order</code>	(global) CHARACTER. Must be 'B' or 'E'. If <code>order = 'B'</code> , the eigenvalues are to be ordered from smallest to largest within each split-off block.

If *order* = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.

n (global) INTEGER. The order of the tridiagonal matrix *T* ($n \geq 0$).

vl, vu (global)
REAL for psstebz
DOUBLE PRECISION for pdstebz.
If *range* = 'V', the routine computes the lower and the upper bounds for the eigenvalues on the interval [*l*, *vu*].
If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu (global)
INTEGER. Constraint: $1 \leq il \leq iu \leq n$.
If *range* = 'I', the index of the smallest eigenvalue is returned for *il* and of the largest eigenvalue for *iu* (assuming that the eigenvalues are in ascending order) must be returned. *il* must be at least 1. *iu* must be at least *il* and no greater than *n*.
If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol (global)
REAL for psstebz
DOUBLE PRECISION for pdstebz.
The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width *abstol*. If *abstol* ≤ 0 , then the tolerance is taken as $ulp ||T||$, where *ulp* is the machine precision, and $||T||$ means the 1-norm of *T*. Eigenvalues will be computed most accurately when *abstol* is set to the underflow threshold `slamch('U')`, not 0. Note that if eigenvectors are desired later by inverse iteration (`p?stein`), *abstol* should be set to $2 * p?lamch('S')$.

d (global)
REAL for psstebz
DOUBLE PRECISION for pdstebz.
Array, DIMENSION (*n*).

	<p>Contains n diagonal elements of the tridiagonal matrix T. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than the $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.</p>
<i>e</i>	<p>(global) REAL for psstebz DOUBLE PRECISION for pdstebz. Array, DIMENSION $(n - 1)$. Contains $(n-1)$ off-diagonal elements of the tridiagonal matrix T. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.</p>
<i>work</i>	<p>(local) REAL for psstebz DOUBLE PRECISION for pdstebz. Array, DIMENSION $\max(5n, 7)$. This is a workspace array.</p>
<i>lwork</i>	<p>(local) INTEGER. The size of the <i>work</i> array must be $\geq \max(5n, 7)$. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.</p>
<i>iwork</i>	<p>(local) INTEGER. Array, DIMENSION $\max(4n, 14)$. This is a workspace array.</p>
<i>liwork</i>	<p>(local) INTEGER. the size of the <i>iwork</i> array must $\geq \max(4n, 14, \text{NPROCS})$. If <i>liwork</i> = -1, then <i>liwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.</p>

Output Parameters

<i>m</i>	(global) INTEGER. The actual number of eigenvalues found. $0 \leq m \leq n$
<i>nsplit</i>	(global) INTEGER. The number of diagonal blocks detected in <i>T</i> . $1 \leq nsplit \leq n$
<i>w</i>	(global) REAL for psstebz DOUBLE PRECISION for pdstebz. Array, DIMENSION (<i>n</i>). On exit, the first <i>m</i> elements of <i>w</i> contain the eigenvalues on all processes.
<i>iblock</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). At each row/column <i>j</i> where <i>e</i> (<i>j</i>) is zero or small, the matrix <i>T</i> is considered to split into a block diagonal matrix. On exit <i>iblock</i> (<i>i</i>) specifies which block (from 1 to the number of blocks) the eigenvalue <i>w</i> (<i>i</i>) belongs to.
<div style="display: flex; align-items: center;"> <div style="margin-right: 10px;"></div> <div> <p>NOTE. In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, <i>info</i> is set to 1 and the ones for which it did not are identified by a negative block number.</p> </div> </div>	
<i>isplit</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). Contains the splitting points, at which <i>T</i> breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), etc., and the <i>nsplit</i> -th consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= <i>n</i> . (Only the first <i>nsplit</i> elements are used, but since the <i>nsplit</i> values are not known, <i>n</i> words must be reserved for <i>isplit</i> .)
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful.

If $info < 0$, if $info = -i$, the i -th argument has an illegal value.

If $info > 0$, some or all of the eigenvalues fail to converge or not computed.

If $info = 1$, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

If $info = 2$, mismatch between the number of eigenvalues output and the number desired.

If $info = 3$: $range='i'$, and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating point arithmetic. Increase the *fudge* parameter, recompile, and try again.

p?stein

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.

Syntax

```
call psstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)
```

```
call pdstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)
```

```
call pcstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)
```

```
call pzstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the eigenvectors of a symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter

lwork. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK routine) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

NOTE. If the eigenvectors obtained are not orthogonal, increase *lwork* and run the code again.

$p = \text{NPROW} * \text{NPCOL}$ is the total number of processes.

Input Parameters

n (global) INTEGER. The order of the matrix T ($n \geq 0$).

m (global) INTEGER. The number of eigenvectors to be returned.

d, *e*, *w* (global)
 REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors.
 Arrays: $d(*)$ contains the diagonal elements of T .
 DIMENSION (n).
 $e(*)$ contains the off-diagonal elements of T .
 DIMENSION ($n-1$).
 $w(*)$ contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array w from `p?stebz` with `order = 'B'` is expected. The array should be replicated in all processes.)
 DIMENSION(m)

iblock (global) INTEGER.
 Array, DIMENSION (n). The submatrix indices associated with the corresponding eigenvalues in $w--1$ for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array *iblock* from `p?stebz` is expected here).

isplit (global) INTEGER.

	<p>Array, <code>DIMENSION (n)</code>. The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <code>isplit(1)</code>, the second of rows/columns <code>isplit(1)+1</code> through <code>isplit(2)</code>, etc., and the <code>nsplit</code>-th consists of rows/columns <code>isplit(nsplit-1)+1</code> through <code>isplit(nsplit)=n</code>. (The output array <code>isplit</code> from p?stebz is expected here.)</p>
<code>orfac</code>	<p>(global)</p> <p>REAL for single-precision flavors</p> <p>DOUBLE PRECISION for double-precision flavors.</p> <p><code>orfac</code> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within <code>orfac* T </code> of each other are to be orthogonalized. However, if the workspace is insufficient (see <code>lwork</code>), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if <code>orfac</code> is equal to zero. A default value of 1000 is used if <code>orfac</code> is negative. <code>orfac</code> should be identical on all processes</p>
<code>iz, jz</code>	<p>(global) INTEGER. The row and column indices in the global array <code>z</code> indicating the first row and the first column of the submatrix <code>z</code>, respectively.</p>
<code>descz</code>	<p>(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <code>z</code>.</p>
<code>work</code>	<p>(local). REAL for single-precision flavors</p> <p>DOUBLE PRECISION for double-precision flavors.</p> <p>Workspace array, <code>DIMENSION (lwork)</code>.</p>
<code>lwork</code>	<p>(local) INTEGER.</p> <p><code>lwork</code> controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is <code>nvec = floor((lwork-max(5*n, np00*mq00))/n)</code>. Eigenvectors corresponding to eigenvalue clusters of size <code>nvec - ceil(m/p) + 1</code> are guaranteed to be orthogonal (the orthogonality is similar to that obtained from ?stein2).</p>

NOTE. *lwork* must be no smaller than $\max(5*n, np00*mq00) + \text{ceil}(m/p)*n$ and should have the same input value on all processes.

It is the minimum value of *lwork* input on different processes that is significant.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

iwork

(local) INTEGER.

Workspace array, DIMENSION (3*n*+*p*+1).

liwork

(local) INTEGER. The size of the array *iwork*. It must be greater than (3*n*+*p*+1).

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

Output Parameters

z

(local)

REAL for psstein

DOUBLE PRECISION for pdstein

COMPLEX for pcstein

DOUBLE COMPLEX for pzstein.

Array, DIMENSION (*descz*(*dlen*), *n*/NPCOL + NB). *z*

contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See [?stein2](#)). On output, *z* is distributed across the *p* processes in block cyclic format.

<i>work</i> (1)	On exit, <i>work</i> (1) gives a lower bound on the workspace (<i>lwork</i>) that guarantees the user desired orthogonalization (see <i>orfac</i>). Note that this may overestimate the minimum workspace needed.
<i>iwork</i>	On exit, <i>iwork</i> (1) contains the amount of integer workspace required. On exit, the <i>iwork</i> (2) through <i>iwork</i> (<i>p</i> +2) indicate the eigenvectors computed by each process. Process <i>i</i> computes eigenvectors indexed <i>iwork</i> (<i>i</i> +2)+1 through <i>iwork</i> (<i>i</i> +3).
<i>ifail</i>	(global). INTEGER. Array, DIMENSION (<i>m</i>). On normal exit, all elements of <i>ifail</i> are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in ?stein), then <i>info</i> > 0 is returned. If mod(<i>info</i> , <i>m</i> +1) > 0, then for <i>i</i> =1 to mod(<i>info</i> , <i>m</i> +1), the eigenvector corresponding to the eigenvalue <i>w</i> (<i>ifail</i> (<i>i</i>)) failed to converge (<i>w</i> refers to the array of eigenvalues on output).
<i>iclustr</i>	(global) INTEGER. Array, DIMENSION (2* <i>p</i>) This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see <i>lwork</i> , <i>orfac</i> and <i>info</i>). Eigenvectors corresponding to clusters of eigenvalues indexed <i>iclustr</i> (2*I-1) to <i>iclustr</i> (2*I), <i>i</i> = 1 to <i>info</i> /(<i>m</i> +1), could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. <i>iclustr</i> is a zero terminated array ---(<i>iclustr</i> (2*k).ne.0.and. <i>iclustr</i> (2*k+1).eq.0) if and only if <i>k</i> is the number of clusters.
<i>gap</i>	(global) REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The <i>info</i> / <i>m</i> output values in this array correspond to the <i>info</i> /(<i>m</i> +1) clusters indicated by the array <i>iclustr</i> . As a result, the dot product between eigenvectors corresponding to the <i>i</i> -th cluster may be as high as (<i>O</i> (<i>n</i>)* <i>macheps</i>)/ <i>gap</i> (<i>i</i>).

info (global) INTEGER.
If *info* = 0, the execution is successful.
If *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*),
If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
If *info* < 0: if *info* = -*i*, the *i*-th argument had an illegal value.
If *info* > 0: if mod(*info*, *m*+1) = *i*, then *i* eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array *ifail*. If *info*/(*m*+1) = *i*, then eigenvectors corresponding to *i* clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

Nonsymmetric Eigenvalue Problems

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

Table 6-5 lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

Table 6-5 Computational Routines for Solving Nonsymmetric Eigenproblems

Operation performed	General matrix	Orthogonal/Unitary Hessenberg matrix
Reduce to Hessenberg form $A = QHQ^H$	p?gehrd	
Multiply the matrix after reduction		p?ormhr/p?unmhr
Find eigenvalues and Schur factorization		p?lahqr

p?gehrd

Reduces a general matrix to upper Hessenberg form.

Syntax

```
call psgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine reduces a real/complex general distributed matrix sub (*A*) to upper Hessenberg form *H* by an orthogonal or unitary similarity transformation

$$Q'^* \text{sub}(A) Q = H,$$

where $\text{sub}(A) = A(\text{ia}+n-1:\text{ia}+n-1, \text{ja}+n-1:\text{ja}+n-1)$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. It is assumed that sub(<i>A</i>) is already upper triangular in rows <i>ia:ia+ilo-2</i> and <i>ia+ihi:ia+n-1</i> and columns <i>ja:ja+ilo-2</i> and <i>ja+ihi:ja+n-1</i> . (See <i>Application Notes</i> below). If $n > 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set <i>ilo</i> = 1, <i>ihi</i> = <i>n</i> .
<i>a</i>	(local) REAL for psgehrd DOUBLE PRECISION for pdgehrd COMPLEX for pcgehrd DOUBLE COMPLEX for pzgehrd.

Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the n -by- n general distributed matrix $sub(A)$ to be reduced.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix *A*.

work (local)
 REAL for psgehrd
 DOUBLE PRECISION for pdgehrd
 COMPLEX for pcgehrd
 DOUBLE COMPLEX for pzgehrd.
 Workspace array of dimension *lwork*.

lwork (local or global) INTEGER, dimension of the array *work*.
lwork is local input and must be at least
 $lwork \geq NB * NB + NB * \max(ihip+1, ihlp+inlq)$
 where $NB = mb_a = nb_a$,
 $iroffa = \text{mod}(ia-1, NB)$,
 $icoffa = \text{mod}(ja-1, NB)$,
 $ioff = \text{mod}(ia+ilo-2, NB)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW)$, $ihip = \text{numroc}(ihi+iroffa, NB, MYROW, iarow, NPROW)$,
 $ilrow = \text{indxg2p}(ia+ilo-1, NB, MYROW, rsrc_a, NPROW)$,
 $ihlp = \text{numroc}(ihi-ilo+ioff+1, NB, MYROW, ilrow, NPROW)$,
 $ilcol = \text{indxg2p}(ja+ilo-1, NB, MYCOL, csrc_a, NPCOL)$,
 $inlq = \text{numroc}(n-ilo+ioff+1, NB, MYCOL, ilcol, NPCOL)$,
 indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a	On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix H , and the elements below the first subdiagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
τ	(local). REAL for <code>psgehrd</code> DOUBLE PRECISION for <code>pdgehrd</code> COMPLEX for <code>pcgehrd</code> DOUBLE COMPLEX for <code>pzgehrd</code> . Array, DIMENSION at least $\max(ja+n-2)$. The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). Elements $ja:ja+ilo-2$ and $ja+ihi:ja+n-2$ of τ are set to zero. τ is tied to the distributed matrix A .
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo) * H(ilo+1) * \dots * H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $a(ia+ilo+i:ia+ihi-1, ja+ilo+i-2)$, and τ in $\tau(ja+ilo+i-2)$. The contents of $a(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & a & a & a & a & a \\ & & & a & a & a & a \\ & & & & a & a & a \\ & & & & & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ & a & h & h & h & h & a \\ & & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ & & & & & & a \end{bmatrix}$$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?ormhr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

```
call psormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)

call pdormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine overwrites the general real distributed m -by- n matrix `sub(C) = C(ic:ic+m-1, jc:jc+n-1)` with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^T * sub(C)$	$sub(C) * Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by [p?gehrd](#).

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

$side$	(global) CHARACTER = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
$trans$	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix <code>sub (C)</code> ($m \geq 0$).

<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub (<i>c</i>) ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. <i>ilo</i> and <i>ihi</i> must have the same values as in the previous call of <code>p?gehrd</code> . <i>Q</i> is equal to the unit matrix except for the distributed submatrix $Q(ia+ilo:ia+ihi-1, ia+ilo:ja+ihi-1)$. If <i>side</i> = 'L', $1 \leq ilo \leq ihi \leq \max(1, m)$; If <i>side</i> = 'R', $1 \leq ilo \leq ihi \leq \max(1, n)$; <i>ilo</i> and <i>ihi</i> are relative indexes.
<i>a</i>	(local) REAL for <code>psormhr</code> DOUBLE PRECISION for <code>pdormhr</code> Pointer into the local memory to an array of dimension $(lld_a, LOCc(ja+m-1))$ if <i>side</i> ='L', and $(lld_a, LOCc(ja+n-1))$ if <i>side</i> = 'R'. Contains the vectors which define the elementary reflectors, as returned by <code>p?gehrd</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <code>psormhr</code> DOUBLE PRECISION for <code>pdormhr</code> Array, DIMENSION $LOCc(ja+m-2)$, if <i>side</i> = 'L', and $LOCc(ja+n-2)$ if <i>side</i> = 'R'. This array contains the scalar factors <i>tau</i> (<i>j</i>) of the elementary reflectors <i>H</i> (<i>j</i>) as returned by <code>p?gehrd</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for <code>psormhr</code> DOUBLE PRECISION for <code>pdormhr</code> Pointer into the local memory to an array of dimension $(lld_c, LOCc(jc+n-1))$.

<i>ic, jc</i>	Contains the local pieces of the distributed matrix sub(<i>c</i>). (global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) REAL for psormhr DOUBLE PRECISION for pdormhr Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> must be at least $iaa = ia + ilo; jaa = ja + ilo - 1;$ If <i>side</i> = 'L', $mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc;$ $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a + nb_a * nb_a)$ else if <i>side</i> = 'R', $mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo;$ $lwork \geq \max((nb_a * (nb_a - 1)) / 2,$ $(nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) +$ $nb_a * nb_a)$ end if where $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(iaa - 1, mb_a),$ $icoffa = \text{mod}(jaa - 1, nb_a),$ $iarow = \text{indxg2p}(iaa, mb_a, MYROW, rsrc_a, NPROW),$ $npa0 = \text{numroc}(ni + iroffa, mb_a, MYROW, iarow, NPROW),$ $iroffc = \text{mod}(icc - 1, mb_c), icoffc = \text{mod}(jcc - 1, nb_c),$ $icrow = \text{indxg2p}(icc, mb_c, MYROW, rsrc_c, NPROW),$ $iccol = \text{indxg2p}(jcc, nb_c, MYCOL, csrc_c, NPCOL),$

```

mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxcg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by p?xerbla.

```

Output Parameters

<i>c</i>	sub(<i>c</i>) is overwritten by $Q \cdot \text{sub}(c)$, or $Q' \cdot \text{sub}(c)$, or $\text{sub}(c) \cdot Q'$, or $\text{sub}(c) \cdot Q$.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unmhr

Multiplies a general matrix by the unitary transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

```

call pcunmhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)

call pzunmhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)

```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine overwrites the general complex distributed m -by- n matrix `sub(C)` = $C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'H':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by [p?gehrd](#).

$$Q = H(ilo) H(ilo+1) \dots H(ihi-1).$$

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix <code>sub(C)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix <code>sub(C)</code> ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to p?gehrd . Q is equal to the unit matrix except in the distributed submatrix $Q_{(ia+ilo:ia+ihi-1, ia+ilo:ja+ihi-1)}$. If $side = 'L'$, then $1 \leq ilo \leq ihi \leq \max(1, m)$. If $side = 'R'$, then $1 \leq ilo \leq ihi \leq \max(1, n)$ <i>ilo</i> and <i>ihi</i> are relative indexes.

<i>a</i>	<p>(local)</p> <p>COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr.</p> <p>Pointer into the local memory to an array of dimension $(lld_a, LOC\ c(ja+m-1))$ if <i>side</i>='L', and $(lld_a, LOCc(ja+n-1))$ if <i>side</i> = 'R'.</p> <p>Contains the vectors which define the elementary reflectors, as returned by p?gehrd.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr.</p> <p>Array, DIMENSION $LOCc(ja+m-2)$, if <i>side</i> = 'L', and $LOCc(ja+n-2)$ if <i>side</i> = 'R'.</p> <p>This array contains the scalar factors $\tau(j)$ of the elementary reflectors $H(j)$ as returned by p?gehrd. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local)</p> <p>COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr.</p> <p>Pointer into the local memory to an array of dimension $(lld_c, LOCc(jc+n-1))$.</p> <p>Contains the local pieces of the distributed matrix sub(<i>c</i>).</p>
<i>ic, jc</i>	<p>(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i>, respectively.</p>
<i>descc</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i>.</p>
<i>work</i>	<p>(local)</p> <p>COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr.</p> <p>Workspace array with dimension <i>lwork</i>.</p>

lwork

(local or global)

The dimension of the array *work*.

lwork must be at least $iaa = ia + ilo$; $jaa = ja + ilo - 1$;
 If *side* = 'L', $mi = ihi - ilo$; $ni = n$; $icc = ic + ilo$;
 $jcc = jc$; $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$
 else if *side* = 'R',
 $mi = m$; $ni = ihi - ilo$; $icc = ic$; $jcc = jc + ilo$;
 $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$
 end if
 where $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(iaa - 1, mb_a)$,
 $icoffa = \text{mod}(jaa - 1, nb_a)$,
 $iarow = \text{indxg2p}(iaa, mb_a, MYROW, rsrc_a, NPROW)$,
 $npa0 = \text{numroc}(ni + iroffa, mb_a, MYROW, iarow, NPROW)$,
 $iroffc = \text{mod}(icc - 1, mb_c)$,
 $icoffc = \text{mod}(jcc - 1, nb_c)$,
 $icrow = \text{indxg2p}(icc, mb_c, MYROW, rsrc_c, NPROW)$,
 $iccol = \text{indxg2p}(jcc, nb_c, MYCOL, csrc_c, NPCOL)$,
 $mpc0 = \text{numroc}(mi + iroffc, mb_c, MYROW, icrow, NPROW)$,
 $nqc0 = \text{numroc}(ni + icoffc, nb_c, MYCOL, iccol, NPCOL)$,
 $ilcm, \text{indxg2p}$ and numroc are ScaLAPACK tool functions;
 $MYROW, MYCOL, NPROW$ and $NPCOL$ can be determined by
 calling the subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by `p_xerbla`.

Output Parameters

<code>c</code>	<code>c</code> is overwritten by $Q^* \text{sub}(c)$ or $Q'^* \text{sub}(c)$ or $\text{sub}(c) * Q'$ or $\text{sub}(c) * Q$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info</code> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = - <i>i</i> .

p?lahqr

Computes the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form.

Syntax

```
call pslahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z,
descz, work, lwork, iwork, ilwork, info)
```

```
call pdlahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z,
descz, work, lwork, iwork, ilwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This is an auxiliary routine used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* to *ihi*.

Input Parameters

<code>wantt</code>	(global) LOGICAL If <code>wantt</code> = .TRUE., the full Schur form T is required; If <code>wantt</code> = .FALSE., only eigenvalues are required.
<code>wantz</code>	(global) LOGICAL.

	<p>If <i>wantz</i> = <code>.TRUE.</code>, the matrix of Schur vectors <i>z</i> is required;</p> <p>If <i>wantz</i> = <code>.FALSE.</code>, Schur vectors are not required.</p>
<i>n</i>	<p>(global) INTEGER. The order of the Hessenberg matrix <i>A</i> (and <i>z</i> if <i>wantz</i>). ($n \geq 0$).</p>
<i>ilo, ihi</i>	<p>(global) INTEGER.</p> <p>It is assumed that <i>A</i> is already upper quasi-triangular in rows and columns <i>ihi</i>+1:<i>n</i>, and that <i>A</i>(<i>ilo</i>, <i>ilo</i>-1) = 0 (unless <i>ilo</i> = 1). <code>p?lahqr</code> works primarily with the Hessenberg submatrix in rows and columns <i>ilo</i> to <i>ihi</i>, but applies transformations to all of <i>h</i> if <i>wantt</i> is <code>.TRUE.</code>.</p> <p>$1 \leq ilo \leq \max(1, ihi); ihi \leq n$.</p>
<i>a</i>	<p>(global)</p> <p>REAL for <code>pslahqr</code> DOUBLE PRECISION for <code>pdlahqr</code> Array, DIMENSION (<i>desca</i>(<i>lld_</i>), *). On entry, the upper Hessenberg matrix <i>A</i>.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p>
<i>iloz, ihiz</i>	<p>(global) INTEGER. Specify the rows of <i>z</i> to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code>.</p> <p>$1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$.</p>
<i>z</i>	<p>(global) REAL for <code>pslahqr</code> DOUBLE PRECISION for <code>pdlahqr</code> Array. If <i>wantz</i> is <code>.TRUE.</code>, on entry <i>z</i> must contain the current matrix <i>Z</i> of transformations accumulated by <code>pdhseqr</code>. If <i>wantz</i> is <code>.FALSE.</code>, <i>z</i> is not referenced.</p>
<i>descz</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i>.</p>
<i>work</i>	<p>(local)</p> <p>REAL for <code>pslahqr</code> DOUBLE PRECISION for <code>pdlahqr</code> Workspace array with dimension <i>lwork</i>.</p>

<i>lwork</i>	(local) INTEGER. The dimension of <i>work</i> . <i>lwork</i> is assumed big enough so that $lwork \geq 3*n + \max(2*\max(descz(lld_), desca(lld_)) + 2*LOCq(n), 7*\text{ceil}(n/hbl)/lcm(NPROW, NPCOL))$. If <i>lwork</i> = -1, then <i>work</i> (1) gets set to the above number and the code returns immediately.
<i>iwork</i>	(global and local) INTEGER array of size <i>ilwork</i> .
<i>ilwork</i>	(local) INTEGER This holds some of the <i>iblk</i> integer arrays.

Output Parameters

<i>a</i>	On exit, if <i>wantt</i> is .TRUE., <i>A</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with any 2-by-2 or larger diagonal blocks not yet in standard form. If <i>wantt</i> is .FALSE., the contents of <i>A</i> are unspecified on exit.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>wr, wi</i>	(global replicated output) REAL for pslahqr DOUBLE PRECISION for pdlahqr Arrays, DIMENSION(<i>n</i>) each. The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)-th, with <i>wi</i> (<i>i</i>) > 0 and <i>wi</i> (<i>i</i> +1) < 0. If <i>wantt</i> is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>A</i> . <i>A</i> may be returned with larger diagonal blocks until the next release.
<i>z</i>	On exit <i>z</i> has been updated; transformations are applied only to the submatrix <i>z</i> (<i>iloz:ihiz</i> , <i>ilo:ihi</i>).
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: parameter number <i>-info</i> incorrect or inconsistent

> 0: p?lahqr failed to compute all the eigenvalues ilo to ihi in a total of $30 * (ihi - ilo + 1)$ iterations; if $info = i$, elements $i+1:ihi$ of wr and wi contain those eigenvalues which have been successfully computed.

Singular Value Decomposition

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general m -by- n matrix A (see “Singular Value Decomposition” in LAPACK chapter).

To find the SVD of a general matrix A , this matrix is first reduced to a bidiagonal matrix B by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of B is computed using the LAPACK routine [?bdsqr](#).

[Table 6-6](#) lists ScaLAPACK computational routines for performing this decomposition.

Table 6-6 Computational Routines for Singular Value Decomposition (SVD)

Operation	General matrix	Orthogonal/unitary matrix
Reduce A to a bidiagonal matrix	p?gebrd	
Multiply matrix after reduction		p?ormbr / p?unmbr

p?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

```
call psgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

This routine reduces a real/complex general m -by- n distributed matrix $sub(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q' * sub(A) * P = B.$$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

Input Parameters

m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Real pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. On entry, this array contains the distributed matrix $\text{sub}(A)$.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .
$work$	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Workspace array of dimension $lwork$.
$lwork$	(local or global) INTEGER, dimension of $work$, must be at least: $lwork \geq nb * (mpa0 + nqa0 + 1) + nqa0$ where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia-1, nb)$, $icoffa = \text{mod}(ja-1, nb)$, $iarow = \text{indxg2p}(ia, nb, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb, MYCOL, csrc_a, NPCOL)$,

```
mpa0 = numroc(m + iroffa, nb, MYROW, iarow,
NPROW),
nqa0 = numroc(n + icoffa, nb, MYCOL, iacol,
NPCOL),
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.
```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array taup , represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array taup , represent the orthogonal matrix P as a product of elementary reflectors. See *Application Notes* below.

d

(local)
 REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors. Array,
 DIMENSION $LOCc(ja + \min(m, n) - 1)$ if $m \geq n$;
 $LOCr(ia + \min(m, n) - 1)$ otherwise. The distributed diagonal
 elements of the bidiagonal matrix B : $d(i) = a(i, i)$.
 d is tied to the distributed matrix A .

e

(local)
 REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Array,
 DIMENSION $LOCr(ia+\min(m,n)-1)$ if $m \geq n$;
 $LOCc(ja+\min(m,n)-2)$ otherwise. The distributed
 off-diagonal elements of the bidiagonal distributed matrix
 B :
 If $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$; if m
 $< n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$. e is tied
 to the distributed matrix A .
tauq, tauq (local)
 REAL for psgebrd
 DOUBLE PRECISION for pdgebrd
 COMPLEX for pcgebrd
 DOUBLE COMPLEX for pzgebrd.
 Arrays, DIMENSION $LOCc(ja+\min(m,n)-1)$ for *tauq* and
 $LOCr(ia+\min(m,n)-1)$ for *tauq*. Contain the scalar factors
 of the elementary reflectors which represent the
 orthogonal/unitary matrices Q and P , respectively. *tauq* and
tauq are tied to the distributed matrix A . See *Application*
Notes below.
work(1) On exit *work(1)* contains the minimum value of *lwork*
 required for optimum performance.
info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -entry had
 an illegal value, then $info = -(i*100+j)$, if the i -th
 argument is a scalar and had an illegal value, then $info =$
 $-i$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1)*H(2)*\dots*H(n), \text{ and } P = G(1)*G(2)*\dots*G(n-1).$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_q * v * v' \text{ and } G(i) = I - \tau_p * u * u'$$

where τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{uq} is stored in $\tau_{uq}(ja+i-1)$ and τ_{up} in $\tau_{up}(ia+i-1)$.

If $m < n$,

$Q = H(1)*H(2)*\dots*H(m-1)$, and $P = G(1)*G(2)*\dots*G(m)$

Each $H(i)$ and $G(i)$ has the form:

$H(i) = i - \tau_{uq} * v * v'$ and $G(i) = i - \tau_{up} * u * u'$

here τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{uq} is stored in $\tau_{uq}(ja+i-1)$ and τ_{up} in $\tau_{up}(ia+i-1)$.

The contents of sub(A) on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6$ ($m < n$):

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

p?ormbr

Multiplies a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
call psormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)

call pdormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

Description

For C interface, this routine is declared in mkl_scalapack.h file.

If $vect = 'Q'$, the routine overwrites the general real distributed m -by- n matrix $sub(C) = C(c:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q \ sub(C)$	$sub(C) \ Q$
$trans = 'T':$	$Q^T \ sub(C)$	$sub(C) \ Q^T$

If $vect = 'P'$, the routine overwrites $sub(C)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$P \ sub(C)$	$sub(C) \ P$
$trans = 'T':$	$P^T \ sub(C)$	$sub(C) \ P^T$

Here Q and P^T are the orthogonal distributed matrices determined by p?gebrd when reducing a real distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q*B*P^T$. Q and P^T are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Thus nq is the order of the orthogonal matrix Q or P^T that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) \ H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) \ H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) \ G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) \ G(2) \dots G(nq-1)$.

Input Parameters

<i>vect</i>	(global) CHARACTER. If $vect = 'Q'$, then Q or Q^T is applied. If $vect = 'P'$, then P or P^T is applied.
<i>side</i>	(global) CHARACTER. If $side = 'L'$, then Q or Q^T , P or P^T is applied from the left. If $side = 'R'$, then Q or Q^T , P or P^T is applied from the right.
<i>trans</i>	(global) CHARACTER. If $trans = 'N'$, no transpose, Q or P is applied. If $trans = 'T'$, then Q^T or P^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub (<i>c</i>).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub (<i>c</i>).
<i>k</i>	(global) INTEGER. If $vect = 'Q'$, the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If $vect = 'P'$, the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$.
<i>a</i>	(local) REAL for <code>psormbr</code> DOUBLE PRECISION for <code>pdormbr</code> . Pointer into the local memory to an array of dimension (<code>lld_a</code> , <code>LOCc(ja+min(nq,k)-1)</code>) If $vect='Q'$, and (<code>lld_a</code> , <code>LOCc(ja+nq-1)</code>)

	<p>If $vect = 'P'$. $nq = m$ if $side = 'L'$, and $nq = n$ otherwise. The vectors which define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P, as returned by <code>p?gebrd</code>.</p>
	<p>If $vect = 'Q'$, $lld_a \geq \max(1, LOCr(ia+nq-1))$; If $vect = 'P'$, $lld_a \geq \max(1, LOCr(ia+\min(nq, k)-1))$.</p>
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .
tau	<p>(local) REAL for <code>psormbr</code> DOUBLE PRECISION for <code>pdormbr</code>. Array, DIMENSION $LOCc(ja+\min(nq, k)-1)$, if $vect = 'Q'$, and $LOCr(ia+\min(nq, k)-1)$, if $vect = 'P'$. $tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P, as returned by <code>pdgebrd</code> in its array argument $tauq$ or $taup$. tau is tied to the distributed matrix A.</p>
c	<p>(local) REAL for <code>psormbr</code> DOUBLE PRECISION for <code>pdormbr</code> Pointer into the local memory to an array of dimension $(lld_a, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix sub (c).</p>
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix C , respectively.
$descc$	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix C .
$work$	<p>(local) REAL for <code>psormbr</code> DOUBLE PRECISION for <code>pdormbr</code>. Workspace array of dimension $lwork$.</p>

lwork

```
(local or global) INTEGER, dimension of work, must be at
least:
If side = 'L'
  nq = m;
  if ((vect = 'Q' and nq ≥ k) or (vect is not equal to 'Q'
  and nq > k)), iaa=ia; jaa=ja; mi=m; ni=n; icc=ic;
  jcc=jc;
  else
    iaa= ia+1; jaa=ja; mi=m-1; ni=n; icc=ic+1; jcc= jc;
  end if
  else
    If side = 'R', nq = n;
    if((vect = 'Q' and nq ≥ k) or (vect is not equal
    to 'Q' and nq > k)),
    iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc;
    else
      iaa= ia; jaa= ja+1; mi= m; ni= n-1; icc= ic; jcc=
      jc+1;
    end if
  end if
  If vect = 'Q',
  If side = 'L', lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
  mpc0)*nb_a) + nb_a * nb_a
  else if side = 'R',
    lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + max(npa0 +
    numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL),
    nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a
  end if
  else if vect is not equal to 'Q', if side = 'L',
    lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + max(mqa0 +
    numroc(numroc(mi+iroffc, mb_a, 0, 0, NPROW),
    mb_a, 0, 0, lcmp), nqc0))*mb_a) + mb_a*mb_a
  else if side = 'R',
    lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a)
    + mb_a*mb_a
  end if
end if
end if
```

where $lcmp = lcm/NPROW$, $lcmq = lcm/NPCOL$, with
 $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(iaa-1, mb_a)$,
 $icoffa = \text{mod}(jaa-1, nb_a)$,
 $iarow = \text{indxg2p}(iaa, mb_a, MYROW, rsrc_a, NPROW)$,
 $iacol = \text{indxg2p}(jaa, nb_a, MYCOL, csrc_a, NPCOL)$,
 $mqa0 = \text{numroc}(mi+icoffa, nb_a, MYCOL, iacol, NPCOL)$,
 $npa0 = \text{numroc}(ni+iroffa, mb_a, MYROW, iarow, NPROW)$,
 $iroffc = \text{mod}(icc-1, mb_c)$,
 $icoffc = \text{mod}(jcc-1, nb_c)$,
 $icrow = \text{indxg2p}(icc, mb_c, MYROW, rsrc_c, NPROW)$,
 $iccol = \text{indxg2p}(jcc, nb_c, MYCOL, csrc_c, NPCOL)$,
 $mpc0 = \text{numroc}(mi+iroffc, mb_c, MYROW, icrow, NPROW)$,
 $nqc0 = \text{numroc}(ni+icoffc, nb_c, MYCOL, iccol, NPCOL)$,
 indxg2p and numroc are ScaLAPACK tool functions; $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p_xerbla`.

Output Parameters

c	On exit, if $vect='Q'$, $\text{sub}(c)$ is overwritten by $Q*\text{sub}(c)$, or $Q'*\text{sub}(c)$, or $\text{sub}(c)*Q'$, or $\text{sub}(c)*Q$; if $vect='P'$, $\text{sub}(c)$ is overwritten by $P*\text{sub}(c)$, or $P'*\text{sub}(c)$, or $\text{sub}(c)*P$, or $\text{sub}(c)*P'$.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful.

< 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmbr

Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
call pcunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

```
call pzunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

If $vect = 'Q'$, the routine overwrites the general complex distributed m -by- n matrix $sub(C)$ = $C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

If $vect = 'P'$, the routine overwrites $sub(C)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$P * sub(C)$	$sub(C) * P$
$trans = 'C':$	$P^H * sub(C)$	$sub(C) * P^H$

Here Q and P^H are the unitary distributed matrices determined by `p?gebrd` when reducing a complex distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q * B * P^H$.

Q and P^H are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Thus nq is the order of the unitary matrix Q or P^H that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) \ H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) \ H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) \ G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) \ G(2) \dots G(nq-1)$.

Input Parameters

<i>vect</i>	(global) CHARACTER. If $vect = 'Q'$, then Q or Q^H is applied. If $vect = 'P'$, then P or P^H is applied.
<i>side</i>	(global) CHARACTER. If $side = 'L'$, then Q or Q^H , P or P^H is applied from the left. If $side = 'R'$, then Q or Q^H , P or P^H is applied from the right.
<i>trans</i>	(global) CHARACTER. If $trans = 'N'$, no transpose, Q or P is applied. If $trans = 'C'$, conjugate transpose, Q^H or P^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub (c) $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub (c) $n \geq 0$.
<i>k</i>	(global) INTEGER. If $vect = 'Q'$, the number of columns in the original distributed matrix reduced by p?gebrd; If $vect = 'P'$, the number of rows in the original distributed matrix reduced by p?gebrd. Constraints: $k \geq 0$.
<i>a</i>	(local) COMPLEX for psormbr DOUBLE COMPLEX for pdormbr.

	<p>Pointer into the local memory to an array of dimension $(lld_a, LOCc(ja+\min(nq, k)-1))$ if $vect='Q'$, and $(lld_a, LOCc(ja+nq-1))$ if $vect = 'P'$. $nq = m$ if $side = 'L'$, and $nq = n$ otherwise. The vectors which define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P, as returned by <code>p?gebrd</code>. If $vect = 'Q'$, $lld_a \geq \max(1, LOCr(ia+nq-1))$; If $vect = 'P'$, $lld_a \geq \max(1, LOCr(ia+\min(nq, k)-1))$.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	<p>(local) COMPLEX for pcunmbr DOUBLE COMPLEX for pzunmbr. Array, DIMENSION $LOCc(ja+\min(nq, k)-1)$, if $vect = 'Q'$, and $LOCr(ia+\min(nq, k)-1)$, if $vect = 'P'$. $tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P, as returned by <code>p?gebrd</code> in its array argument <i>tauq</i> or <i>taup</i>. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local) COMPLEX for pcunmbr DOUBLE COMPLEX for pzunmbr Pointer into the local memory to an array of dimension $(lld_a, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix sub (<i>c</i>).</p>
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	<p>(local) COMPLEX for pcunmbr</p>

lwork

```

DOUBLE COMPLEX for pzunmbr.
Workspace array of dimension lwork.
(local or global) INTEGER, dimension of work, must be at
least:
If side = 'L'
  nq = m;
  if ((vect = 'Q' and nq ≥ k) or (vect is not equal
  to 'Q' and nq > k)), iaa= ia; jaa= ja; mi= m; ni=

NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol,
NPCOL),
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pzerbla*.

Output Parameters

<i>c</i>	On exit, if <i>vect</i> ='Q', <i>sub(c)</i> is overwritten by $Q*sub(C)$, or $Q'*sub(C)$, or $sub(C)*Q'$, or $sub(C)*Q$; if <i>vect</i> ='P', <i>sub(c)</i> is overwritten by $P*sub(C)$, or $P'*sub(C)$, or $sub(C)*P$, or $sub(C)*P'$.
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Generalized Symmetric-Definite Eigen Problems

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see [Generalized Symmetric-Definite Eigenvalue Problems](#) in LAPACK chapters) to standard symmetric eigenvalue problem $C_Y = \lambda_Y$, which you can solve by calling ScaLAPACK routines described earlier in this chapter (see [Symmetric Eigenproblems](#)).

[Table 6-7](#) lists these routines.

Table 6-7 Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to standard problems	p?sygst	p?hegst

p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pssygst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info )

call pdsygst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info )
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following `sub(A)` denotes $A(ia:ia+n-1, ja:ja+n-1)$ and `sub(B)` denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If `ibtype = 1`, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x,$$

and `sub(A)` is overwritten by $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$.

If `ibtype = 2` or `3`, the problem is

$$\text{sub}(A) * \text{sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x,$$

and `sub(A)` is overwritten by $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$.

`sub(B)` must have been previously factorized as $U^T * U$ or $L * L^T$ by `p?potrf`.

Input Parameters

<code>ibtype</code>	(global) INTEGER. Must be 1 or 2 or 3. If <code>itype = 1</code> , compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$; If <code>itype = 2</code> or <code>3</code> , compute $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$.
<code>uplo</code>	(global) CHARACTER. Must be 'U' or 'L'.

If $uplo = 'U'$, the upper triangle of $sub(A)$ is stored and $sub(B)$ is factored as $U^T * U$.
 If $uplo = 'L'$, the lower triangle of $sub(A)$ is stored and $sub(B)$ is factored as $L * L^T$.

n (global) INTEGER. The order of the matrices $sub(A)$ and $sub(B)$ ($n \geq 0$).

a (local)
 REAL for pssygst
 DOUBLE PRECISION for pdsygst.
 Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. On entry, the array contains the local pieces of the n -by- n symmetric distributed matrix $sub(A)$.
 If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.
 If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix *A*.

b (local)
 REAL for pssygst
 DOUBLE PRECISION for pdsygst.
 Pointer into the local memory to an array of dimension $(lld_b, LOCC(jb+n-1))$. On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $sub(B)$ as returned by p?potrf.

ib, jb (global) INTEGER. The row and column indices in the global array *b* indicating the first row and the first column of the submatrix *B*, respectively.

descb (global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix *B*.

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(<i>A</i>).
<i>scale</i>	(global) REAL for pssygst DOUBLE PRECISION for pdsygst. Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?hegst

Reduces a Hermitian-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pchegst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info)

call pzhegst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine reduces complex Hermitian-definite generalized eigenproblems to the standard form.

In the following sub(*A*) denotes *A*(*ia:ia+n-1, ja:ja+n-1*) and sub(*B*) denotes *B*(*ib:ib+n-1, jb:jb+n-1*).

If *ibtype* = 1, the problem is

$\text{sub}(A) * x = \lambda * \text{sub}(B) * x,$

and $\text{sub}(A)$ is overwritten by $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$.

If $\text{ibtype} = 2$ or 3 , the problem is

$\text{sub}(A) * \text{sub}(B) * x = \lambda * x$, or $\text{sub}(B) * \text{sub}(A) * x = \lambda * x,$

and $\text{sub}(A)$ is overwritten by $U * \text{sub}(A) * U^H$, or $L^H * \text{sub}(A) * L$.

$\text{sub}(B)$ must have been previously factorized as $U^H * U$ or $L * L^H$ by `p?potrf`.

Input Parameters

ibtype (global) INTEGER. Must be 1 or 2 or 3.
 If $\text{itype} = 1$, compute $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$;
 If $\text{itype} = 2$ or 3 , compute $U * \text{sub}(A) * U^H$, or $L^H * \text{sub}(A) * L$.

uplo (global) CHARACTER. Must be 'U' or 'L'.
 If $\text{uplo} = 'U'$, the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^H * U$.
 If $\text{uplo} = 'L'$, the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L * L^H$.

n (global) INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).

a (local)
 COMPLEX for `pchegst`
 DOUBLE COMPLEX for `pzhgst`.
 Pointer into the local memory to an array of dimension $(\text{lld_a}, \text{LOC}(ja+n-1))$. On entry, the array contains the local pieces of the n -by- n Hermitian distributed matrix $\text{sub}(A)$. If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $\text{uplo} = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for <i>pchegst</i> DOUBLE COMPLEX for <i>pzhegst</i> . Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb+n-1)</i>). On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub (<i>B</i>) as returned by <i>p?potrf</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(<i>A</i>).
<i>scale</i>	(global) REAL for <i>pchegst</i> DOUBLE PRECISION for <i>pzhegst</i> . Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Driver Routines

Table 6-8 lists ScaLAPACK driver routines available for solving systems of linear equations, linear least-squares problems, standard eigenvalue and singular value problems, and generalized symmetric definite eigenproblems.

Table 6-8 ScaLAPACK Driver Routines

Type of Problem	Matrix type, storage scheme	Driver
Linear equations	general (partial pivoting)	p?gesv (simple driver) p?gesvx (expert driver)
	general band (partial pivoting)	p?gbsv (simple driver)
	general band (no pivoting)	p?dbsv (simple driver)
	general tridiagonal (no pivoting)	p?dtsv (simple driver)
	symmetric/Hermitian positive-definite	p?posv (simple driver) p?posvx (expert driver)
	symmetric/Hermitian positive-definite, band	p?pbsv (simple driver)
	symmetric/Hermitian positive-definite, tridiagonal	p?ptsv (simple driver)
Linear least squares problem	general m -by- n	p?gels
Symmetric eigenvalue problem	symmetric/Hermitian	p?syev (simple driver) p?syevx / p?heevx (expert driver)
Singular value decomposition	general m -by- n	p?gesvd
Generalized symmetric definite eigenvalue problem	symmetric/Hermitian, one matrix also positive-definite	p?sygvx / p?hegvx (expert driver)

p?gesv

Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.

Syntax

```
call psgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine `p?gesv` computes the solution to a real or complex system of linear equations $\text{sub}(A) * X = \text{sub}(B)$, where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is an n -by- n distributed matrix and X and $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. L and U are stored in $\text{sub}(A)$. The factored form of $\text{sub}(A)$ is then used to solve the system of equations $\text{sub}(A) * X = \text{sub}(B)$.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides, that is, the number of columns of the distributed submatrices B and X ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for <code>psgesv</code> DOUBLE PRECISION for <code>pdgesv</code> COMPLEX for <code>pcgesv</code> DOUBLE COMPLEX for <code>pzgesv</code> . Pointers into the local memory to arrays of local dimension $a(\text{lld_a}, \text{LOCc}(\text{ja}+n-1))$ and $b(\text{lld_b}, \text{LOCc}(\text{jb}+nrhs-1))$, respectively. On entry, the array <i>a</i> contains the local pieces of the n -by- n distributed matrix $\text{sub}(A)$ to be factored. On entry, the array <i>b</i> contains the right hand side distributed matrix $\text{sub}(B)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	Overwritten by the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P^*L^*U$; the unit diagonal elements of <i>L</i> are not stored .
<i>b</i>	Overwritten by the solution distributed matrix <i>x</i> .
<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> is $(\text{LOCr}(m_a) + mb_a)$. This array contains the pivoting information. The (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv(i)</i> . This array is tied to the distributed matrix <i>A</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. <i>info</i> > 0: If <i>info</i> = <i>k</i> , $U(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution could not be computed.

p?gesvx

*Uses the LU factorization to compute the solution to the system of linear equations with a square matrix **A** and multiple right-hand sides, and provides error bounds on the solution.*

Syntax

```
call psgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, iwork, liwork, info)
```

```
call pdgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, iwork, liwork, info)
```

```
call pcgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, rwork, lrwork, info)
```

```
call pzgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, rwork, lrwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $AX = B$, where **A** denotes the n -by- n submatrix $A(ia:ia+n-1, ja:ja+n-1)$, **B** denotes the n -by- $nrhs$ submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ and **X** denotes the n -by- $nrhs$ submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$.

Error bounds on the solution and a condition estimate are also provided.

In the following description, *af* stands for the subarray $af(iaf:iaf+n-1, jaf:jaf+n-1)$.

The routine `p?gesvx` performs the following steps:

1. If *fact* = 'E', real scaling factors *R* and *C* are computed to equilibrate the system:

$$trans = 'N': \text{diag}(R) * A * \text{diag}(C) \quad * \text{diag}(C)^{-1} * X = \text{diag}(R) * B$$

$$trans = 'T': (\text{diag}(R) * A * \text{diag}(C))^T * \text{diag}(R)^{-1} * X = \text{diag}(C) * B$$

$trans = 'C': (\text{diag}(R) * A * \text{diag}(C))^H * \text{diag}(R) - 1 * X = \text{diag}(C) * B$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if $trans='N'$) or $\text{diag}(C) * B$ (if $trans = 'T'$ or $'C'$).

2. If $fact = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as $A = P L U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if $trans = 'N'$) or $\text{diag}(R)$ (if $trans = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

fact (global) CHARACTER*1. Must be 'F', 'N', or 'E'.
 Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
 If $fact = 'F'$ then, on entry, af and $ipiv$ contain the factored form of A . If $equed$ is not 'N', the matrix A has been equilibrated with scaling factors given by r and c . Arrays a , af , and $ipiv$ are not modified.
 If $fact = 'N'$, the matrix A is copied to af and factored.
 If $fact = 'E'$, the matrix A is equilibrated if necessary, then copied to af and factored.

trans (global) CHARACTER*1. Must be 'N', 'T', or 'C'.
 Specifies the form of the system of equations:
 If $trans = 'N'$, the system has the form $A * X = B$ (No transpose);
 If $trans = 'T'$, the system has the form $A^T * X = B$ (Transpose);

	<p>If $trans = 'C'$, the system has the form $A^H * X = B$ (Conjugate transpose);</p>
<i>n</i>	(global) INTEGER. The number of linear equations; the order of the submatrix A ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrices B and X ($nrhs \geq 0$).
<i>a, af, b, work</i>	<p>(local)</p> <p>REAL for psgesvx DOUBLE PRECISION for pdgesvx COMPLEX for pcgesvx DOUBLE COMPLEX for pzgesvx.</p> <p>Pointers into the local memory to arrays of local dimension $a(lld_a, LOCC(ja+n-1))$, $af(lld_af, LOCC(ja+n-1))$, $b(lld_b, LOCC(jb+nrhs-1))$, $work(lwork)$, respectively. The array a contains the matrix A. If $fact = 'F'$ and $equed$ is not 'N', then A must have been equilibrated by the scaling factors in r and/or c.</p> <p>The array af is an input argument if $fact = 'F'$. In this case it contains on entry the factored form of the matrix A, that is, the factors L and U from the factorization $A = P * L * U$ as computed by p?getrf. If $equed$ is not 'N', then af is the factored form of the equilibrated matrix A.</p> <p>The array b contains on entry the matrix B whose columns are the right-hand sides for the systems of equations.</p> <p>$work(*)$ is a workspace array. The dimension of $work$ is ($lwork$).</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix A .
<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global array af indicating the first row and the first column of the subarray $af(iaf:iaf+n-1, jaf:jaf+n-1)$, respectively.

<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix <i>B(ib:ib+n-1, jb:jb+nrhs-1)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> is $(LOCr(m_a)+mb_a)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. On entry, it contains the pivot indices from the factorization $A = P^*L*U$ as computed by <i>p?getrf</i> ; (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv(i)</i> . This array must be aligned with <i>A(ia:ia+n-1, *)</i> .
<i>equed</i>	(global) CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'); If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag(r)</i> ; If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag(c)</i> ; If <i>equed</i> = 'B', both row and column equilibration was done; <i>A</i> has been replaced by <i>diag(r)*A*diag(c)</i> .
<i>r, c</i>	(local) REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCr(m_a)$ and $LOCc(n_a)$, respectively. The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag(r)</i> ; if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive.

If *equed* = 'C' or 'B', *A* is multiplied on the right by *diag(c)*; if *equed* = 'N' or 'R', *c* is not accessed.
 If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive. Array *r* is replicated in every process column, and is aligned with the distributed matrix *A*. Array *c* is replicated in every process row, and is aligned with the distributed matrix *A*.

<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix <i>X(ix:ix+n-1, jx:jx+nrhs-1)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i> .
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> ; must be at least $\max(\text{p?gecon}(lwork), \text{p?gerfs}(lwork)) + LOCr(n_a)$.
<i>iwork</i>	(local, psgesvx/pdgesvx only) INTEGER. Workspace array. The dimension of <i>iwork</i> is (<i>liwork</i>).
<i>liwork</i>	(local, psgesvx/pdgesvx only) INTEGER. The dimension of the array <i>iwork</i> , must be at least <i>LOCr(n_a)</i> .
<i>rwork</i>	(local) REAL for pcgesvx DOUBLE PRECISION for pzgesvx. Workspace array, used in complex flavors only. The dimension of <i>rwork</i> is (<i>lrwork</i>).
<i>lrwork</i>	(local or global, pcgesvx/pzgesvx only) INTEGER. The dimension of the array <i>rwork</i> ; must be at least $2 * LOCc(n_a)$.

Output Parameters

<i>x</i>	(local) REAL for psgesvx DOUBLE PRECISION for pdgesvx COMPLEX for pcgesvx DOUBLE COMPLEX for pzgesvx. Pointer into the local memory to an array of local dimension <i>x(lld_x, LOCc(jx+nrhs-1))</i> .
----------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	<p>If $info = 0$, the array x contains the solution matrix X to the <i>original</i> system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the <i>equilibrated</i> system is:</p> <p>$diag(C)^{-1} * X$, if $trans = 'N'$ and $equed = 'C'$ or $'B'$; and $diag(R)^{-1} * X$, if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$.</p>
a	<p>Array a is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.</p> <p>If $equed \neq 'N'$, A is scaled on exit as follows:</p> <p>$equed = 'R'$: $A = diag(R) * A$ $equed = 'C'$: $A = A * diag(c)$ $equed = 'B'$: $A = diag(R) * A * diag(c)$</p>
af	<p>If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.</p>
b	<p>Overwritten by $diag(R) * B$ if $trans = 'N'$ and $equed = 'R'$ or $'B'$; overwritten by $diag(c) * B$ if $trans = 'T'$ and $equed = 'C'$ or $'B'$; not changed if $equed = 'N'$.</p>
r, c	<p>These arrays are output arguments if $fact \neq 'F'$. See the description of r, c in <i>Input Arguments</i> section.</p>
$rcond$	<p>(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A after equilibration (if done). The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.</p>
$ferr, berr$	<p>(local) REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p>

	Arrays, DIMENSION $LOCc(n_b)$ each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector. Arrays <i>ferr</i> and <i>berr</i> are both replicated in every process row, and are aligned with the matrices <i>B</i> and <i>X</i> .
<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> ≠ 'F' , then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>work</i> (1)	If <i>info</i> =0, on exit <i>work</i> (1) returns the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	If <i>info</i> =0, on exit <i>iwork</i> (1) returns the minimum value of <i>liwork</i> required for optimum performance.
<i>rwork</i> (1)	If <i>info</i> =0, on exit <i>rwork</i> (1) returns the minimum value of <i>lrwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. If <i>info</i> = <i>i</i> , and $i \leq n$, then $U(i,i)$ is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution and error bounds could not be computed. If <i>info</i> = <i>i</i> , and $i = n + 1$, then <i>U</i> is nonsingular, but <i>rcond</i> is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

p?gbsv

Computes the solution to the system of linear equations with a general banded distributed matrix and multiple right-hand sides.

Syntax

```
call psgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
```

```
call pdgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
```

```
call pcgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
```

```
call pzgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine `p?gbsv` computes the solution to a real or complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real/complex general banded distributed matrix with bwl subdiagonals and bwu superdiagonals, and X and $\text{sub}(B) = B(ib:ib+n-1, 1:rhs)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U * Q$, where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Input Parameters

n (global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

<i>bwl</i>	(global) INTEGER. The number of subdiagonals within the band of <i>A</i> ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of superdiagonals within the band of <i>A</i> ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix sub(<i>B</i>) ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for psgbsv DOUBLE PRECISION for pdgbsv COMPLEX for pcgbsv DOUBLE COMPLEX for pzgbsv. Pointers into the local memory to arrays of local dimension <i>a</i> (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)) and <i>b</i> (<i>lld_b</i> , <i>LOCc</i> (<i>nrhs</i>)), respectively. On entry, the array <i>a</i> contains the local pieces of the global array <i>A</i> . On entry, the array <i>b</i> contains the right hand side distributed matrix sub(<i>B</i>).
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb</i> (<i>dtype_</i>) = 502, then <i>dlen_</i> ≥ 7; else if <i>descb</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>work</i>	(local)

REAL for psgbsv
 DOUBLE PRECISION for pdgbsv
 COMPLEX for pcgbsv
 DOUBLE COMPLEX for pzgbsv.
 Workspace array of dimension (*lwork*).

lwork (local or global) INTEGER. The size of the array *work*, must be at least $lwork \geq (NB+bwu) * (bwl+bwu) + 6 * (bwl+bwu) * (bwl+2*bwu) + \max(nrhs * (NB+2*bwl+4*bwu), 1)$.

Output Parameters

a On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

b On exit, this array contains the local pieces of the solution distributed matrix *x*.

ipiv (local) INTEGER array.
 The dimension of *ipiv* must be at least *desca*(NB). This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info INTEGER. If *info*=0, the execution is successful. *info* < 0:
 If the *i*th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*th argument is a scalar and had an illegal value, then *info* = -*i*.
info > 0:
 If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not nonsingular, and the factorization was not completed. If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbsv

Solves a general band system of linear equations.

Syntax

```
call psdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pddbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pcdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pzdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine solves the system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded diagonally dominant-like distributed matrix with bandwidth bwl, bwu .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix A , ($n \geq 0$).
bwl	(global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.
bwu	(global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.
$nrhs$	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B , ($nrhs \geq 0$).
a	(local). REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv.

	<p>Pointer into the local memory to an array with first dimension $lld_a \geq (bwl+bwu+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension <i>dlen</i>. If 1d type (<i>dtype_a</i>=501 or 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_a</i>=1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i>. Contains information of mapping of <i>A</i> to memory.</p>
<i>b</i>	<p>(local) REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv. Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.</p>
<i>ib</i>	<p>(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).</p>
<i>descb</i>	<p>(global and local) INTEGER array of dimension <i>dlen</i>. If 1d type (<i>dtype_b</i> =502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i>. Contains information of mapping of <i>B</i> to memory.</p>
<i>work</i>	<p>(local). REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv.</p>

Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork

(local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

$lwork \geq$

$nb(bwl+bwu) + 6 \max(bwl, bwu) * \max(bwl, bwu) + \max(\max(bwl, bwu) nrhs, \max(bwl, bwu) * \max(bwl, bwu))$

Output Parameters

a

On exit, this array contains information containing details of the factorization.

Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

b

On exit, this contains the local piece of the solutions distributed matrix *x*.

work

On exit, *work*(1) contains the minimal *lwork*.

info

(local) INTEGER. If *info*=0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

> 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?dtsv

Solves a general tridiagonal system of linear equations.

Syntax

```
call psdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pddtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pcdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pzdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into $L U$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed submatrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right hand sides; the number of columns of the distributed matrix B ($nrhs \geq 0$).
<i>dl</i>	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, <i>dl</i> (1) is not referenced, and <i>dl</i> must be aligned with <i>d</i> . Must be of size $> desca(nb_)$.
<i>d</i>	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv

	<p>COMPLEX for psdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the main diagonal of the matrix.</p>
<i>du</i>	<p>(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, <i>du</i>(<i>n</i>) is not referenced, and <i>du</i> must be aligned with <i>d</i>.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension <i>dlen</i>. If 1d type (<i>dtype_a</i>=501 or 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_a</i>=1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i>. Contains information of mapping of <i>A</i> to memory.</p>
<i>b</i>	<p>(local) REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer into the local memory to an array of local lead dimension <i>lld_b</i> > <i>nb</i>. On entry, this array contains the local pieces of the right hand sides <i>B</i>(<i>ib:ib+n-1</i>, 1:<i>nrhs</i>).</p>
<i>ib</i>	<p>(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).</p>
<i>descb</i>	<p>(global and local) INTEGER array of dimension <i>dlen</i>. If 1d type (<i>dtype_b</i> =502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i>. Contains information of mapping of <i>B</i> to memory.</p>

work (local).
 REAL for psdtsv
 DOUBLE PRECISION for pddtsv
 COMPLEX for pcdtsv
 DOUBLE COMPLEX for pzdtsv. Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned. *lwork* > (12*NPCOL+3*nb)+max((10+2*min(100, nrhs))*NPCOL+4*nrhs, 8*NPCOL)

Output Parameters

dl On exit, this array contains information containing the * factors of the matrix.

d On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*(*nb_*).

du On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*(*nb_*).

b On exit, this contains the local piece of the solutions distributed matrix *X*.

work On exit, *work*(1) contains the minimal *lwork*.

info (local) INTEGER. If *info*=0, the execution is successful.
 < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
 > 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
 If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?posv

Solves a symmetric positive definite system of linear equations.

Syntax

```
call psposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pcposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pzposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the solution to a real/complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and is an n -by- n symmetric/Hermitian distributed positive definite matrix and X and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices. The Cholesky decomposition is used to factor $\text{sub}(A)$ as

$$\text{sub}(A) = U^T * U, \text{ if } uplo = 'U', \text{ or}$$

$$\text{sub}(A) = L * L^T, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of $\text{sub}(A)$ is then used to solve the system of equations.

Input Parameters

<i>uplo</i>	(global). CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a</i>	(local)

	<p>REAL for psposv DOUBLE PRECISION for pdposv COMPLEX for pcposv COMPLEX*16 for pzposv. Pointer into the local memory to an array of dimension $(lld_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the n-by-n symmetric distributed matrix $sub(A)$ to be factored. If $uplo = 'U'$, the leading n-by-n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n-by-n lower triangular part of $sub(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	<p>(local) REAL for psposv DOUBLE PRECISION for pdposv COMPLEX for pcposv COMPLEX*16 for pzposv. Pointer into the local memory to an array of dimension $(lld_b, LOC(jb+nrhs-1))$. On entry, the local pieces of the right hand sides distributed matrix $sub(B)$.</p>
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, this array contains the local pieces of the factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $L * L^H$.
<i>b</i>	On exit, if <i>info</i> = 0, <i>sub(B)</i> is overwritten by the solution distributed matrix <i>x</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. If <i>info</i> > 0: If <i>info</i> = <i>k</i> , the leading minor of order <i>k</i> , $A(ia:ia+k-1, ja:ja+k-1)$ is not positive definite, and the factorization could not be completed, and the solution has not been computed.

p?posvx

Solves a symmetric or Hermitian positive definite system of linear equations.

Syntax

```
call psposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

```
call pdposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

```
call pcposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

```
call pzposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine uses the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ to compute the solution to a real or complex system of linear equations

$$A(ia:ia+n-1, ja:ja+n-1)*X = B(ib:ib+n-1, jb:jb+nrhs-1),$$

where $A(ia:ia+n-1, ja:ja+n-1)$ is a n -by- n matrix and X and $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments y denotes $Y(iy:iy+m-1, jy:jy+k-1)$ a m -by- k matrix where y can be a, af, b and x .

The routine `p?posvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(sr)*A*\text{diag}(sc)*\text{inv}(\text{diag}(sc))*X = \text{diag}(sr)*B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(sr)*A*\text{diag}(sc)$ and B by $\text{diag}(sr)*B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T*U, \text{ if } uplo = 'U', \text{ or}$$

$$A = L*L^T, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(sr)$ so that it solves the original system before equilibration.

Input Parameters

`fact` (global) CHARACTER. Must be 'F', 'N', or 'E'.

	Specifies whether or not the factored form of the matrix <i>A</i> is supplied on entry, and if not, whether the matrix <i>A</i> should be equilibrated before it is factored. If <i>fact</i> = 'F': on entry, <i>af</i> contains the factored form of <i>A</i> . If <i>equed</i> = 'Y', the matrix <i>A</i> has been equilibrated with scaling factors given by <i>s</i> . <i>a</i> and <i>af</i> will not be modified. If <i>fact</i> = 'N', the matrix <i>A</i> will be copied to <i>af</i> and factored. If <i>fact</i> = 'E', the matrix <i>A</i> will be equilibrated if necessary, then copied to <i>af</i> and factored.
<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix sub(<i>A</i>) (<i>n</i> ≥ 0).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrices <i>B</i> and <i>X</i> . (<i>nrhs</i> ≥ 0).
<i>a</i>	(local) REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx. Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, the symmetric/Hermitian matrix <i>A</i> , except if <i>fact</i> = 'F' and <i>equed</i> = 'Y', then <i>A</i> must contain the equilibrated matrix <i>diag(sr)*A*diag(sc)</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>A</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>A</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>A</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>A</i> is not referenced. <i>A</i> is not modified if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N' on exit.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>af</i>	(local) REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx. Pointer into the local memory to an array of local dimension (<i>lld_af</i> , <i>LOCc(ja+n-1)</i>). If <i>fact</i> = 'F', then <i>af</i> is an input argument and on entry contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as <i>A</i> . If <i>equed</i> ≠ 'N', then <i>af</i> is the factored form of the equilibrated matrix $\text{diag}(sr) * A * \text{diag}(sc)$.
<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global array <i>af</i> indicating the first row and the first column of the submatrix <i>AF</i> , respectively.
<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>AF</i> .
<i>equed</i>	(global). CHARACTER. Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'); If <i>equed</i> = 'Y', equilibration was done and <i>A</i> has been replaced by $\text{diag}(sr) * A * \text{diag}(sc)$.
<i>sr</i>	(local) REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx. Array, DIMENSION (<i>lld_a</i>).

	<p>The array <i>s</i> contains the scale factors for <i>A</i>. This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument.</p> <p>If <i>equed</i> = 'N', <i>s</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.</p>
<i>b</i>	<p>(local)</p> <p>REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx.</p> <p>Pointer into the local memory to an array of local dimension (<i>lld_b</i>, <i>LOCc(jb+nrhs-1)</i>). On entry, the <i>n</i>-by-<i>nrhs</i> right-hand side matrix <i>B</i>.</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i>, respectively.</p>
<i>descb</i>	<p>(global and local) INTEGER. Array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i>.</p>
<i>x</i>	<p>(local)</p> <p>REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx.</p> <p>Pointer into the local memory to an array of local dimension (<i>lld_x</i>, <i>LOCc(jx+nrhs-1)</i>).</p>
<i>ix, jx</i>	<p>(global) INTEGER. The row and column indices in the global array <i>x</i> indicating the first row and the first column of the submatrix <i>x</i>, respectively.</p>
<i>descx</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i>.</p>
<i>work</i>	<p>(local)</p> <p>REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx.</p> <p>Workspace array, DIMENSION (<i>lwork</i>).</p>

lwork (local or global) INTEGER.
 The dimension of the array *work*. *lwork* is local input and must be at least $lwork = \max(p?pocon(lwork), p?porfs(lwork)) + LOCr(n_a)$.
 $lwork = 3*desca(lld_)$.
 If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

iwork (local) INTEGER. Workspace array, dimension (*liwork*).

liwork (local or global) INTEGER. The dimension of the array *iwork*. *liwork* is local input and must be at least $liwork = desca(lld_)$ $liwork = LOCr(n_a)$.
 If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a On exit, if *fact* = 'E' and *equed* = 'Y', *a* is overwritten by $\text{diag}(sr)*a*\text{diag}(sc)$.

af If *fact* = 'N', then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^T*U$ or $A = L*L^T$ of the original matrix *A*.
 If *fact* = 'E', then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^T*U$ or $A = L*L^T$ of the equilibrated matrix *A* (see the description of *A* for the form of the equilibrated matrix).

equed If *fact* \neq 'F', then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

<i>sr</i>	<p>This array is an output argument if <i>fact</i> \neq 'F'. See the description of <i>sr</i> in <i>Input Arguments</i> section.</p>
<i>sc</i>	<p>This array is an output argument if <i>fact</i> \neq 'F'. See the description of <i>sc</i> in <i>Input Arguments</i> section.</p>
<i>b</i>	<p>On exit, if <i>equed</i> = 'N', <i>b</i> is not modified; if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B', <i>b</i> is overwritten by $\text{diag}(r) * b$; if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'C' or 'B', <i>b</i> is overwritten by $\text{diag}(c) * b$.</p>
<i>x</i>	<p>(local) REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx. If <i>info</i> = 0 the <i>n</i>-by-<i>nrhs</i> solution matrix <i>x</i> to the original system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> \neq 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(sc)) * X$ if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B', or $\text{inv}(\text{diag}(sr)) * X$ if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'.</p>
<i>rcond</i>	<p>(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i>=0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.</p>
<i>ferr</i>	<p>REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(LOC, n_b)$. The estimated forward error bounds for each solution vector <i>x</i>(<i>j</i>) (the <i>j</i>-th column of the solution matrix <i>x</i>). If <i>xtrue</i> is the true solution, <i>ferr</i>(<i>j</i>) bounds the magnitude of the largest entry in $(X(j) - xtrue)$ divided by the magnitude of the largest</p>

entry in $x(j)$. The quality of the error bound depends on the quality of the estimate of $\text{norm}(\text{inv}(A))$ computed in the code; if the estimate of $\text{norm}(\text{inv}(A))$ is accurate, the error bound is guaranteed.

berr

(local)

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(LOC, n_b)$. The componentwise relative backward error of each solution vector $x(j)$ (the smallest relative change in any entry of A or B that makes $x(j)$ an exact solution).

work(1)

(local) On exit, *work(1)* returns the minimal and optimal *liwork*.

info

(global) INTEGER.

If *info*=0, the execution is successful.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value

> 0: if *info* = *i*, and *i* is $\leq n$: if *info* = *i*, the leading minor of order *i* of *a* is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

= *n*+1: *rcond* is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

p?pbsv

Solves a symmetric/Hermitian positive definite banded system of linear equations.

Syntax

```
call pspbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pdpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pcpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pzpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded symmetric positive definite distributed matrix with bandwidth bw .

Cholesky factorization is used to factor a reordering of the matrix into $L * L'$.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular of A is stored. If <i>uplo</i> = 'U', the upper triangular A is stored If <i>uplo</i> = 'L', the lower triangular of A is stored.
<i>n</i>	(global) INTEGER. The order of the distributed matrix A ($n \geq 0$).
<i>bw</i>	(global) INTEGER. The number of subdiagonals in L or U . $0 \leq bw \leq n-1$.
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a</i>	(local). REAL for pspbsv DOUBLE PRECISION for pdpbsv COMPLEX for pcpbsv DOUBLE COMPLEX for pzpbsv. Pointer into the local memory to an array with first dimension $lld_a \geq (bw+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix $sub(A)$ to be factored.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix A .

<i>b</i>	<p>(local)</p> <p>REAL for pspbsv DOUBLE PRECISION for pdpbsv COMPLEX for pcpbsv DOUBLE COMPLEX for pzpbsv.</p> <p>Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.</p>
<i>ib</i>	<p>(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).</p>
<i>descb</i>	<p>(global and local) INTEGER array of dimension <i>dlen</i>.</p> <p>If 1D type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; If 2D type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9.</p> <p>The array descriptor for the distributed matrix <i>B</i>. Contains information of mapping of <i>B</i> to memory.</p>
<i>work</i>	<p>(local).</p> <p>REAL for pspbsv DOUBLE PRECISION for pdpbsv COMPLEX for pcpbsv DOUBLE COMPLEX for pzpbsv.</p> <p>Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER. Size of user-input workspace <i>work</i>. If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i>(1) and an error code is returned. <i>lwork</i> $\geq (nb+2*bw)*bw + \max((bw*nrhs), bw*bw)$</p>

Output Parameters

<i>a</i>	<p>On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.</p>
<i>b</i>	<p>On exit, contains the local piece of the solutions distributed matrix <i>x</i>.</p>

work
info

On exit, *work*(1) contains the minimal *lwork*.
(global). INTEGER. If *info*=0, the execution is successful.
< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
> 0: If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

psptsv

Solves a symmetric or Hermitian positive definite tridiagonal system of linear equations.

Syntax

```
call psptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pdptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pcptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pzptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real tridiagonal symmetric positive definite distributed matrix.

Cholesky factorization is used to factor a reordering of the matrix into $L * L'$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of matrix <i>A</i> ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix <i>B</i> ($nrhs \geq 0$).
<i>d</i>	(local) REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Pointer to local part of global vector storing the main diagonal of the matrix.
<i>e</i>	(local) REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, <i>du</i> (<i>n</i>) is not referenced, and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_a</i> =501 or 502), $dlen \geq 7$; If 2d type (<i>dtype_a</i> =1), $dlen \geq 9$. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$.

	On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned. <i>lwork</i> > (12*NPCOL+3* <i>nb</i>)+max((10+2*min(100, <i>nrhs</i>))*NPCOL+4* <i>nrhs</i> , 8*NPCOL).

Output Parameters

<i>d</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> (<i>nb_</i>).
<i>e</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> (<i>nb_</i>).
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix <i>x</i> .
<i>work</i>	On exit, <i>work</i> (1) contains the minimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. If <i>info</i> =0, the execution is successful.

< 0 : If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0 : If $info = k \leq NPROCS$, the submatrix stored on processor $info$ and factored locally was not positive definite, and the factorization was not completed.

If $info = k > NPROCS$, the submatrix stored on processor $info-NPROCS$ representing interactions with other processors was not positive definite, and the factorization was not completed.

p?gels

Solves overdetermined or underdetermined linear systems involving a matrix of full rank.

Syntax

```
call psgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

```
call pdgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

```
call pcgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

```
call pzgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, or its transpose/ conjugate-transpose, using a QTQ or LQ factorization of $\text{sub}(A)$. It is assumed that $\text{sub}(A)$ has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

minimize $||\text{sub}(B) - \text{sub}(A) * X||$

2. If $\text{trans} = \text{'N'}$ and $m < n$: find the minimum norm solution of an underdetermined system
 $\text{sub}(A) * X = \text{sub}(B)$.

3. If $\text{trans} = \text{'T'}$ and $m \geq n$: find the minimum norm solution of an undetermined system
 $\text{sub}(A)^T * X = \text{sub}(B)$.

4. If $\text{trans} = \text{'T'}$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

minimize $||\text{sub}(B) - \text{sub}(A)^T * X||$,

where $\text{sub}(B)$ denotes $B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+\text{nrhs}-1)$ when $\text{trans} = \text{'N'}$ and $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1)$ otherwise. Several right hand side vectors b and solution vectors x can be handled in a single call; when $\text{trans} = \text{'N'}$, the solution vectors are stored as the columns of the n -by- nrhs right hand side matrix $\text{sub}(B)$ and the m -by- nrhs right hand side matrix $\text{sub}(B)$ otherwise.

Input Parameters

<i>trans</i>	(global) CHARACTER. Must be 'N', or 'T'. If $\text{trans} = \text{'N'}$, the linear system involves matrix $\text{sub}(A)$; If $\text{trans} = \text{'T'}$, the linear system involves the transposed matrix A^T (for real flavors only).
<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns in the distributed submatrices $\text{sub}(B)$ and X . ($\text{nrhs} \geq 0$).
<i>a</i>	(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels.

	<p>Pointer into the local memory to an array of dimension $(lld_a, LOCc(ja+n-1))$. On entry, contains the m-by-n matrix A.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A.</p>
<i>b</i>	<p>(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels. Pointer into the local memory to an array of local dimension $(lld_b, LOCc(jb+nrhs-1))$. On entry, this array contains the local pieces of the distributed matrix B of right-hand side vectors, stored columnwise; $sub(B)$ is m-by-$nrhs$ if $trans='N'$, and n-by-$nrhs$ otherwise.</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the global array b indicating the first row and the first column of the submatrix B, respectively.</p>
<i>descb</i>	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix B.</p>
<i>work</i>	<p>(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels. Workspace array with dimension $lwork$.</p>
<i>lwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>work</i> $lwork$ is local input and must be at least $lwork \geq ltau + \max(lwf, lws)$, where if $m > n$, then $ltau = numroc(ja + \min(m, n) - 1, nb_a, MYCOL, csrc_a, NPCOL),$ $lwf = nb_a * (mpa0 + nqa0 + nb_a)$</p>

```

lws = max((nb_a*(nb_a-1))/2, (nrhsqb0 +
mpb0)*nb_a) + nb_a*nb_a
else
ltau = numroc(ia+min(m,n)-1, mb_a, MYROW,
rsrc_a, NPROW),
lwf = mb_a * (mpa0 + nqa0 + mb_a)
lws = max((mb_a*(mb_a-1))/2, (npb0 + max(nqa0 +
numroc(numroc(n+iroffb, mb_a, 0, 0, NPROW),
mb_a, 0, 0, lcmp), nrhsqb0))*mb_a) + mb_a*mb_a
end if,
where lcmp = lcm/NPROW with lcm = ilcm(NPROW,
NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol= indxg2p(ja, nb_a, MYROW, rsrc_a, NPROW)
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol,
NPCOL),
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow,
NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW, and NPCOL can be determined by
calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>a</i>	On exit, If $m \geq n$, $\text{sub}(A)$ is overwritten by the details of its QR factorization as returned by <code>p?geqrf</code> ; if $m < n$, $\text{sub}(A)$ is overwritten by details of its LQ factorization as returned by <code>p?gelqf</code> .
<i>b</i>	On exit, $\text{sub}(B)$ is overwritten by the solution vectors, stored columnwise: if $trans = 'N'$ and $m \geq n$, rows 1 to n of $\text{sub}(B)$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to m in that column; If $trans = 'N'$ and $m < n$, rows 1 to n of $\text{sub}(B)$ contain the minimum norm solution vectors; If $trans = 'T'$ and $m \geq n$, rows 1 to m of $\text{sub}(B)$ contain the minimum norm solution vectors; if $trans = 'T'$ and $m < n$, rows 1 to m of $\text{sub}(B)$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to n in that column.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?syev

Computes selected eigenvalues and eigenvectors of a symmetric matrix.

Syntax

```
call pssyev( jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
info )
```

```
call pdsyev( jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
info )
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* by calling the recommended sequence of ScaLAPACK routines.

In its present form, the routine assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global). CHARACTER. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global). CHARACTER. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* ($n \geq 0$).

<i>a</i>	<p>(local)</p> <p>REAL for pssyev.</p> <p>DOUBLE PRECISION for pdsyev.</p> <p>Block cyclic array of global dimension (n, n) and local dimension $(lld_a, LOC\ c(ja+n-1))$. On entry, the symmetric matrix <i>A</i>.</p> <p>If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the symmetric matrix.</p> <p>If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the symmetric matrix.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>A</i>.</p>
<i>iz, jz</i>	<p>(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i>, respectively.</p>
<i>descz</i>	<p>(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix <i>Z</i>.</p>
<i>work</i>	<p>(local)</p> <p>REAL for pssyev.</p> <p>DOUBLE PRECISION for pdsyev.</p> <p>Array, DIMENSION (<i>lwork</i>).</p>
<i>lwork</i>	<p>(local) INTEGER. See below for definitions of variables used to define <i>lwork</i>.</p> <p>If no eigenvectors are requested (<i>jobz</i> = 'N'), then <i>lwork</i></p> $\geq 5*n + sizesytrd + 1,$ <p>where <i>sizesytrd</i> is the workspace for <i>p?sytrd</i> and is $\max(NB*(np + 1), 3*NB)$.</p> <p>If eigenvectors are requested (<i>jobz</i> = 'V') then the amount of workspace required to guarantee that all eigenvectors are computed is:</p> $qrmem = 2*n-2$ $lwmin = 5*n + n*ldc + \max(sizemqrleft, qrmem) + 1$ <p>Variable definitions:</p>

```

nb = desca(mb_) = desca(nb_) = descz(mb_) =
descz(nb_);
nn = max(n, nb, 2);
desca(rsrc_) = desca(rsrc_) = descz(rsrc_) =
descz(csrc_) = 0
np = numroc(nn, nb, 0, 0, NPROW)
nq = numroc(max(n, nb, 2), nb, 0, 0, NPCOL)
nrc = numroc(n, nb, myprowc, 0, NPROCS)
ldc = max(1, nrc)
sizemqrleft is the workspace for p?ormtr when its side
argument is 'L'.
myprowc is defined when a new context is created as follows:
call blacs_get(desca(ctxt_), 0, contextc)
call blacs_gridinit(contextc, 'R', NPROCS, 1)
call blacs_gridinfo(contextc, nprowc, npcolc,
myprowc, mypcolc)
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by p?erbla.

```

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> ='U') of <i>A</i> , including the diagonal, is destroyed.
<i>w</i>	(global). REAL for pssyev DOUBLE PRECISION for pdsyev Array, DIMENSION (<i>n</i>). On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). REAL for pssyev DOUBLE PRECISION for pdsyev Array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.

If `jobz = 'N'`, then `z` is not referenced.

`work(1)` On output, `work(1)` returns the workspace needed to guarantee completion. If the input parameters are incorrect, `work(1)` may also be incorrect.

If `jobz = 'N'` `work(1)` = minimal (optimal) amount of workspace

If `jobz = 'V'` `work(1)` = minimal workspace required to generate all the eigenvectors.

`info` (global) INTEGER.

If `info = 0`, the execution is successful.

If `info < 0`: If the *i*-th argument is an array and the *j*-entry had an illegal value, then `info = -(i*100+j)`, if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

If `info > 0`:

If `info = 1` through *n*, the *i*-th eigenvalue did not converge in `?steqr2` after a total of `30n` iterations.

If `info = n+1`, then `p?syeval` has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from `p?syeval` cannot be guaranteed.

p?syeval

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

```
call pssyeval(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr,
gap, info)
```

```
call pdsyeval(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr,
gap, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

$jobz$ (global). CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:
 If $jobz = 'N'$, then only eigenvalues are computed.
 If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

$range$ (global). CHARACTER*1. Must be 'A', 'V', or 'I'.
 If $range = 'A'$, all eigenvalues will be found.
 If $range = 'V'$, all eigenvalues in the half-open interval $[vl, vu]$ will be found.
 If $range = 'I'$, the eigenvalues with indices il through iu will be found.

$uplo$ (global). CHARACTER*1. Must be 'U' or 'L'.
 Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
 If $uplo = 'U'$, a stores the upper triangular part of A .
 If $uplo = 'L'$, a stores the lower triangular part of A .

n (global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).

a (local). REAL for pssyevx
 DOUBLE PRECISION for pdsyevx.
 Block cyclic array of global dimension (n, n) and local dimension $(lld_a, LOCC(ja+n-1))$. On entry, the symmetric matrix A .
 If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the symmetric matrix.
 If $uplo = 'L'$, only the lower triangular part of A is used to define the elements of the symmetric matrix.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>vl, vu</i>	(global) REAL for pssyevx DOUBLE PRECISION for pdsyevx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	(global) INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1$ $\min(il, n) \leq iu \leq n$ Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	(global). REAL for pssyevx DOUBLE PRECISION for pdsyevx. If <i>jobz</i> ='V', setting <i>abstol</i> to $p?lamch(context, 'U')$ yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b)$, where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with $((\text{mod}(info, 2) \neq 0) \text{ or } * (\text{mod}(info/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.

<i>orfac</i>	<p>(global). REAL for pssyevx DOUBLE PRECISION for pdsyevx. Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol=orfac*norm(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.</p>
<i>iz, jz</i>	<p>(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>z</i>, respectively.</p>
<i>descz</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>z</i>. <i>descz(ctxt_)</i> must equal <i>desca(ctxt_)</i>.</p>
<i>work</i>	<p>(local) REAL for pssyevx. DOUBLE PRECISION for pdsyevx. Array, DIMENSION (<i>lwork</i>).</p>
<i>lwork</i>	<p>(local) INTEGER. The dimension of the array <i>work</i>. See below for definitions of variables used to define <i>lwork</i>. If no eigenvectors are requested (<i>jobz</i> = 'N'), then <i>lwork</i> $\geq 5*n + \max(5*nn, NB*(np0 + 1)).$ <p>If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:</p> $lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) + \text{iceil}(neig, NPROW*NPCOL)*nn$ <p>The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and <i>orfac</i> is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to <i>lwork</i>:</p> $(clustersize-1)*n,$ </p>

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j)\} + orfac*2*norm(A),$$

where

neig = number of eigenvectors requested

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);

nn = max(*n*, *nb*, 2);

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0;

np0 = numroc(*nn*, *nb*, 0, 0, NPROW);

mq0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL)

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x/y*)

If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.

Relationship between workspace, orthogonality & performance:

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$$lwork \geq \max(lwork, 5*n + nsytrd_lwopt),$$

where *lwork*, as defined previously, depends upon the number of eigenvectors requested, and

$$nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;$$

```
anb = pjlaenv(desca(ctxt_), 3, 'p?sytttrd', 'L',
0, 0, 0, 0);
```

```
sqnpc = int(sqrt(dble(NPROW * NPCOL)));
```

```
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb);
```

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

For large n , no extra workspace is needed, however the biggest boost in performance comes for small n , so it is wise to provide the extra workspace (typically less than a megabyte per process).

If $clustersize > n/\sqrt{NPROW \cdot NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $clustersize = n-1$) p?stein will perform no better than ?stein on single processor.

For $clustersize = n/\sqrt{NPROW \cdot NPCOL}$

reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW \cdot NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by p?erbla.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*. $liwork \geq 6 \cdot nnp$

Where: $nnp = \max(n, NPROW \cdot NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of

these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>m</i>	(global) INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.
<i>nz</i>	(global) INTEGER. Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of <i>z</i> that are filled. If <i>jobz</i> \neq 'V', <i>nz</i> is not referenced. If <i>jobz</i> = 'V', <i>nz</i> = <i>m</i> unless the user supplies insufficient space and <code>p?syevx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in <i>z</i> (<i>m.le.descz(n_)</i>) and sufficient workspace to compute them. (See <i>lwork</i>). <code>p?syevx</code> is always able to detect insufficient space without computation unless <i>range.eq.</i> 'V'.
<i>w</i>	(global). REAL for <code>pssyevx</code> DOUBLE PRECISION for <code>pdsyevx</code> . Array, DIMENSION (<i>n</i>). The first <i>m</i> elements contain the selected eigenvalues in ascending order.
<i>z</i>	(local). REAL for <code>pssyevx</code> DOUBLE PRECISION for <code>pdsyevx</code> . Array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> .

	If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i> (1)	On exit, returns workspace adequate workspace to allow optimal performance.
<i>iwork</i> (1)	On return, <i>iwork</i> (1) contains the amount of integer workspace required.
<i>ifail</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). If <i>jobz</i> = 'V', then on normal exit, the first <i>m</i> elements of <i>ifail</i> are zero. If (mod(<i>info</i> ,2) .ne.0) on exit, then <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.
<i>iclustr</i>	(global) INTEGER. Array, DIMENSION (2*NPROW*NPCOL) This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see <i>lwork</i> , <i>orfac</i> and <i>info</i>). Eigenvectors corresponding to clusters of eigenvalues indexed <i>iclustr</i> (2*i-1) to <i>iclustr</i> (2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. <i>iclustr</i> () is a zero terminated array. (<i>iclustr</i> (2*k).ne.0. and. <i>iclustr</i> (2*k+1).eq.0) if and only if <i>k</i> is the number of clusters. <i>iclustr</i> is not referenced if <i>jobz</i> = 'N'.
<i>gap</i>	(global) REAL for pssyevx DOUBLE PRECISION for pdsyevx. Array, DIMENSION (NPROW*NPCOL) This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array <i>iclustr</i> . As a result, the dot product between eigenvectors corresponding to the <i>i</i> th cluster may be as high as (<i>C</i> * <i>n</i>)/ <i>gap</i> (<i>i</i>) where <i>C</i> is a small constant.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0:

If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$: if $(mod(info,2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in $ifail$. Ensure $abstol=2.0*p?lamch('U')$.

If $(mod(info/2,2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array $iclustr$.

If $(mod(info/4,2) \neq 0)$, then space limit prevented $p?syevxf$ from computing all of the eigenvectors between vl and vu . The number of eigenvectors computed is returned in nz .

If $(mod(info/8,2) \neq 0)$, then $p?stebz$ failed to compute eigenvalues. Ensure $abstol=2.0*p?lamch('U')$.

p?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
call pcheevx( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork,
ifail, iclustr, gap, info )
```

```
call pzheevx( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork,
ifail, iclustr, gap, info )
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	(global). CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval [<i>vl</i> , <i>vu</i>] will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	(global). CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	(local). COMPLEX for pcheevx DOUBLE COMPLEX for pzheevx. Block cyclic array of global dimension (<i>n</i> , <i>n</i>) and local dimension (<i>lld_a</i> , <i>LOC c(ja+n-1)</i>). On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.

<i>desca</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>. If <i>desca(ctxt_)</i> is incorrect, <i>p?heevx</i> cannot guarantee correct error reporting</p>
<i>vl, vu</i>	<p>(global) REAL for <i>pcheevx</i> DOUBLE PRECISION for <i>pzheevx</i>. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <i>range</i> = 'A' or 'I'.</p>
<i>il, iu</i>	<p>(global) INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1; \min(il, n) \leq iu \leq n$. Not referenced if <i>range</i> = 'A' or 'V'.</p>
<i>abstol</i>	<p>(global). REAL for <i>pcheevx</i> DOUBLE PRECISION for <i>pzheevx</i>. If <i>jobz</i>='V', setting <i>abstol</i> to <i>p?lamch(context, 'U')</i> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b)$, where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues are computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$, not zero. If this routine returns with $((\text{mod}(\text{info}, 2) \neq 0) \text{ or } (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.</p>
<i>orfac</i>	<p>(global). REAL for <i>pcheevx</i> DOUBLE PRECISION for <i>pzheevx</i>.</p>

	<p>Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.</p>
<i>iz, jz</i>	<p>(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i>, respectively.</p>
<i>descz</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i>. <i>descz</i>(<i>ctxt_</i>) must equal <i>desca</i>(<i>ctxt_</i>).</p>
<i>work</i>	<p>(local) COMPLEX for <i>pcheevx</i> DOUBLE COMPLEX for <i>pzheevx</i>. Array, DIMENSION (<i>lwork</i>).</p>
<i>lwork</i>	<p>(local). INTEGER. The dimension of the array <i>work</i>. If only eigenvalues are requested: $lwork \geq n + \max(nb * (np0 + 1), 3)$ If eigenvectors are requested: $lwork \geq n + (np0 + mq0 + nb) * nb$ with $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$. $lwork \geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{iceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$ For optimal performance, greater workspace is needed, that is $lwork \geq \max(lwork, \text{nhetrd_lwork})$ where <i>lwork</i> is as defined above, and <i>nhetrd_lwork</i> = $n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$ $ictxt = \text{desca}(\text{ctxt_})$ $anb = \text{pjlaenv}(ictxt, 3, 'pchettrd', 'L', 0, 0, 0, 0)$ $sqnpc = \text{sqrt}(\text{dble}(\text{NPROW} * \text{NPCOL}))$</p>

```

nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the size
required for optimal performance for all work arrays. Each
of these values is returned in the first entry of the
corresponding work arrays, and no error message is issued
by pxxerbla.

rwork      (local)
            REAL for pcheevx
            DOUBLE PRECISION for pzheevx.
            Workspace array, DIMENSION (lrwork).

lrwork     (local) INTEGER. The dimension of the array work.
            See below for definitions of variables used to define lrwork.
            If no eigenvectors are requested (jobz = 'N'), then
            lrwork ≥ 5*nn+4*n.
            If eigenvectors are requested (jobz = 'V'), then the
            amount of workspace required to guarantee that all
            eigenvectors are computed is:
            lrwork ≥ 4*n + max(5*nn, np0*mq0+2*nb*nb) +
            iceil(neig, NPROW*NPCOL)*nn
            The computed eigenvectors may not be orthogonal if the
            minimal workspace is supplied and orfac is too small. If
            you want to guarantee orthogonality (at the cost of
            potentially poor performance) you should add the following
            values to lrwork:
            (clustersize-1)*n,
            where clustersize is the number of eigenvalues in the
            largest cluster, where a cluster is defined as a set of close
            eigenvalues:
            {w(k), ..., w(k+clustersize-1) | w(j+1) ≤
            w(j)+orfac*2*norm(A)}.
            Variable definitions:
            neig = number of eigenvectors requested;
            nb = desca(mb_) = desca(nb_) = descz(mb_) =
            descz(nb_);
            nn = max(n, NB, 2);

```

```
desca(rsrc_) = desca(nb_) = descz(rsrc_) =
descz(csrc_) = 0;
np0 = numroc(nn, nb, 0, 0, NPROW);
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL);
iceil(x, y) is a ScaLAPACK function returning ceiling(x/y)
```

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, `p?heevx` attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned. Note that when *range*='V', `p?heevx` does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow `p?heevx` to compute the eigenvalues, `p?heevx` will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If $clustersize \geq n/\sqrt{NPROW \cdot NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) `p?stein` will perform no better than `?stein` on 1 processor.

For $clustersize = n/\sqrt{NPROW \cdot NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW \cdot NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

iwork (local) INTEGER. Workspace array.
liwork (local) INTEGER, dimension of *iwork*.
 $liwork \geq 6 * nnp$
 Where: $nnp = \max(n, NPROW * NPCOL + 1, 4)$
 If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m (global) INTEGER. The total number of eigenvalues found;
 $0 \leq m \leq n$.

nz (global) INTEGER. Total number of eigenvectors computed.
 $0 \leq nz \leq m$.
 The number of columns of *z* that are filled.
 If *jobz* \neq 'V', *nz* is not referenced.
 If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and p_?heevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (*m.le.descz(n_)*) and sufficient workspace to compute them. (See *lwork*). p_?heevx is always able to detect insufficient space without computation unless *range.eq.*'V'.

w (global).
 REAL for pcheevx
 DOUBLE PRECISION for pzheevx.
 Array, DIMENSION (*n*). The first *m* elements contain the selected eigenvalues in ascending order.

z (local).

COMPLEX for pcheevx
DOUBLE COMPLEX for pzheevx.
Array, global dimension (n, n), local dimension ($lld_z, LOcc(jz+n-1)$).
If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
If $jobz = 'N'$, then z is not referenced.

work(1) On exit, returns workspace adequate workspace to allow optimal performance.

rwork (local).
REAL for pcheevx
DOUBLE PRECISION for pzheevx.
Array, DIMENSION (*lrwork*). On return, *rwork(1)* contains the optimal amount of workspace required for efficient execution.
If $jobz='N'$ *rwork(1)* = optimal amount of workspace required to compute eigenvalues efficiently.
If $jobz='V'$ *rwork(1)* = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.
If $range='V'$, it is assumed that all eigenvectors may be required.

iwork(1) (local)
On return, *iwork(1)* contains the amount of integer workspace required.

ifail (global) INTEGER.
Array, DIMENSION (n).
If $jobz = 'V'$, then on normal exit, the first m elements of *ifail* are zero. If $(mod(info, 2) \neq 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.
If $jobz = 'N'$, then *ifail* is not referenced.

iclustr (global) INTEGER.
Array, DIMENSION ($2*NPROW*NPCOL$).

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array. (*iclustr*(2*k).ne.0. and. *iclustr*(2*k+1).eq.0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array, DIMENSION (NPROW*NPCOL)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n)/gap(i)$ where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(i*100+j), if the *i*-th argument is a scalar and had an illegal value, then *info* = -i.

If *info* > 0:

If (mod(*info*,2).ne.0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U')

If (mod(*info*/2,2).ne.0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented `p?syevx` from computing all of the eigenvectors between `vl` and `vu`. The number of eigenvectors computed is returned in `nz`.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then `p?stebz` failed to compute eigenvalues. Ensure `abstol=2.0*p?lamch('U')`.

p?gesvd

Computes the singular value decomposition of a general matrix, optionally computing the left and/or right singular vectors.

Syntax

```
call psgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
             ivt, jvt, descvt, work, lwork, info )
```

```
call pdgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
             ivt, jvt, descvt, work, lwork, info )
```

```
call pcgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
             ivt, jvt, descvt, work, lwork, rwork, info )
```

```
call pzgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
             ivt, jvt, descvt, work, lwork, rwork, info )
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the singular value decomposition (SVD) of an m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix that is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A and the columns of U and V are the corresponding right and left singular vectors, respectively. The singular values are returned in array `s` in decreasing order and only the first $\min(m, n)$ columns of U and rows of `vt` = V^T are computed.

Input Parameters

mp = number of local rows in A and U

nq = number of local columns in A and VT

$size = \min(m, n)$

$sizeq$ = number of local columns in U

$sizep$ = number of local rows in VT

$jobu$ (global). CHARACTER*1. Specifies options for computing all or part of the matrix U .
 If $jobu = 'V'$, the first $size$ columns of U (the left singular vectors) are returned in the array u ;
 If $jobu = 'N'$, no columns of U (no left singular vectors) are computed.

$jobvt$ (global) CHARACTER*1.
 Specifies options for computing all or part of the matrix V^T .
 If $jobvt = 'V'$, the first $size$ rows of V^T (the right singular vectors) are returned in the array vt ;
 If $jobvt = 'N'$, no rows of V^T (no right singular vectors) are computed.

m (global) INTEGER. The number of rows of the matrix A ($m \geq 0$).

n (global) INTEGER. The number of columns in A ($n \geq 0$).

a (local). REAL for psgesvd
 DOUBLE PRECISION for pdgesvd
 COMPLEX for pcgesvd
 COMPLEX*16 for pzgesvd
 Block cyclic array, global dimension (m, n) , local dimension (mp, nq) .
 $work(lwork)$ is a workspace array.

ia, ja (global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

$desca$ (global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A .

<i>iu, ju</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>U</i> , respectively.
<i>descu</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>U</i> .
<i>ivt, jvt</i>	(global) INTEGER. The row and column indices in the global array <i>vt</i> indicating the first row and the first column of the submatrix <i>VT</i> , respectively.
<i>descvt</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>VT</i> .
<i>work</i>	(local). REAL for <i>psgesvd</i> DOUBLE PRECISION for <i>pdgesvd</i> COMPLEX for <i>pcgesvd</i> COMPLEX*16 for <i>pzgesvd</i> Workspace array, dimension (<i>lwork</i>)
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> ; <i>lwork</i> > 2 + 6* <i>sizeb</i> + max(<i>watobd</i> , <i>wbdtosvd</i>), where <i>sizeb</i> = max(<i>m</i> , <i>n</i>), and <i>watobd</i> and <i>wbdtosvd</i> refer, respectively, to the workspace required to bidiagonalize the matrix <i>A</i> and to go from the bidiagonal matrix to the singular value decomposition <i>U S VT</i> . For <i>watobd</i> , the following holds: <i>watobd</i> = max(max(<i>wp?lange</i> , <i>wp?gebrd</i>), max(<i>wp?lared2d</i> , <i>wp?lared1d</i>)), where <i>wp?lange</i> , <i>wp?lared1d</i> , <i>wp?lared2d</i> , <i>wp?gebrd</i> are the workspaces required respectively for the subprograms <i>p?lange</i> , <i>p?lared1d</i> , <i>p?lared2d</i> , <i>p?gebrd</i> . Using the standard notation <i>mp</i> = numroc(<i>m</i> , <i>mb</i> , MYROW, <i>desca(ctxt_)</i> , NPROW), <i>nq</i> = numroc(<i>n</i> , <i>nb</i> , MYCOL, <i>desca(lld_)</i> , NPCOL), the workspaces required for the above subprograms are <i>wp?lange</i> = <i>mp</i> , <i>wp?lared1d</i> = <i>nq</i> 0, <i>wp?lared2d</i> = <i>mp</i> 0, <i>wp?gebrd</i> = <i>nb</i> *(<i>mp</i> + <i>nq</i> + 1) + <i>nq</i> ,

where $nq0$ and $mp0$ refer, respectively, to the values obtained at $MYCOL = 0$ and $MYROW = 0$. In general, the upper limit for the workspace is given by a workspace required on processor (0,0):

$$watobd \leq nb * (mp0 + nq0 + 1) + nq0.$$

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For *wbdtosvd*, the following holds:

$$wbdtosvd = size * (wantu * nru + wantvt * ncvt) + \max(w?bdsqr, \max(wantu * wp?ormbrqln, wantvt * wp?ormbrprt)),$$

where

$wantu(wantvt) = 1$, if left/right singular vectors are wanted, and $wantu(wantvt) = 0$, otherwise. $w?bdsqr$, $wp?ormbrqln$, and $wp?ormbrprt$ refer respectively to the workspace required for the subprograms *?bdsqr*, *p?ormbr(qln)*, and *p?ormbr(prt)*, where *qln* and *prt* are the values of the arguments *vect*, *side*, and *trans* in the call to *p?ormbr*. *nru* is equal to the local number of rows of the matrix *U* when distributed 1-dimensional "column" of processes. Analogously, *ncvt* is equal to the local number of columns of the matrix *VT* when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure *?bdsqr* requires

$$w?bdsqr = \max(1, 2 * size + (2 * size - 4) * \max(wantu, wantvt))$$

on every processor. Finally,

$$\begin{aligned} wp?ormbrqln &= \max((nb * (nb - 1)) / 2, \\ &\quad (sizeq + mp) * nb + nb * nb, \\ wp?ormbrprt &= \max((mb * (mb - 1)) / 2, \\ &\quad (sizep + nq) * mb + mb * mb, \end{aligned}$$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum size for the work array. The required workspace is returned as the first element of *work* and no error message is issued by *pxerbla*.

rwork

REAL for *psgesvd*

DOUBLE PRECISION for pdgesvd
 COMPLEX for pcgesvd
 COMPLEX*16 for pzgesvd
 Workspace array, dimension $(1 + 4 * sizeb)$

Output Parameters

<i>a</i>	On exit, the contents of <i>a</i> are destroyed.
<i>s</i>	(global). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd Array, DIMENSION (<i>size</i>). Contains the singular values of <i>A</i> sorted so that $s(i) \geq s(i+1)$.
<i>u</i>	(local). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd local dimension (<i>mp</i> , <i>sizeq</i>), global dimension (<i>m</i> , <i>size</i>) If <i>jobu</i> = 'V', <i>u</i> contains the first $\min(m, n)$ columns of <i>U</i> . If <i>jobu</i> = 'N' or 'O', <i>u</i> is not referenced.
<i>vt</i>	(local). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd local dimension (<i>sizep</i> , <i>nq</i>), global dimension (<i>size</i> , <i>n</i>) If <i>jobvt</i> = 'V', <i>vt</i> contains the first <i>size</i> rows of V^T if <i>jobu</i> = 'N', <i>vt</i> is not referenced.
<i>work</i>	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i>	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required size of <i>rwork</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value.

If $info > 0$ i , then if ?bdsqr did not converge,
 If $info = \min(m, n) + 1$, then p?gesvd has detected
 heterogeneity by finding that eigenvalues were not identical
 across the process grid. In this case, the accuracy of the
 results from p?gesvd cannot be guaranteed.

p?sygvx

*Computes selected eigenvalues and, optionally,
 eigenvectors of a real generalized symmetric
 definite eigenproblem.*

Syntax

```
call pssygvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork,
liwork, ifail, iclustr, gap, info)
```

```
call pdsygvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork,
liwork, ifail, iclustr, gap, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \text{ sub}(A) \text{ sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here x denotes eigen vectors, λ (*lambda*) denotes eigenvalues, $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ is assumed to symmetric, and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Input Parameters

<i>ibtype</i>	<p>(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \lambda \text{sub}(B) * x$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \lambda \text{sub}(A) * x$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \lambda \text{sub}(B) * x$.</p>
<i>jobz</i>	<p>(global). CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>range</i>	<p>(global). CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues in the interval: $[\text{vl}, \text{vu}]$ If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i>.</p>
<i>uplo</i>	<p>(global). CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$.</p>
<i>n</i>	<p>(global). INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$, $n \geq 0$.</p>
<i>a</i>	<p>(local) REAL for pssygvx DOUBLE PRECISION for pdsygvx. Pointer into the local memory to an array of dimension $(\text{lld_a}, \text{LOCc}(ja+n-1))$. On entry, this array contains the local pieces of the <i>n</i>-by-<i>n</i> symmetric distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.</p>

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, p?sygvx cannot guarantee correct error reporting.
<i>b</i>	(local). REAL for pssygvx DOUBLE PRECISION for pdsygvx. Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb+n-1)</i>). On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric distributed matrix sub(<i>B</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>B</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . <i>descb(ctxt_)</i> must be equal to <i>desca(ctxt_)</i> .
<i>vl, vu</i>	(global) REAL for pssygvx DOUBLE PRECISION for pdsygvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global) INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1, \min(il, n) \leq iu \leq n$ If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	(global)

	<p>REAL for pssygvx DOUBLE PRECISION for pdsygvx. If <i>jobz</i>='V', setting <i>abstol</i> to $p?lamch(context, 'U')$ yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b)$, where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with $(\text{mod}(\text{info}, 2) .ne. 0) .or. * (\text{mod}(\text{info}/8, 2) .ne. 0)$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.</p>
<i>orfac</i>	<p>(global). REAL for pssygvx DOUBLE PRECISION for pdsygvx. Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.</p>
<i>iz, jz</i>	<p>(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i>, respectively.</p>
<i>descz</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i>. <i>descz(ctxt_)</i> must equal <i>desca(ctxt_)</i>.</p>
<i>work</i>	<p>(local)</p>

lwork

REAL for pssygvx
 DOUBLE PRECISION for pdsygvx.
 Workspace array, dimension (*lwork*)

(local) INTEGER.

Dimension of the array *work*. See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lwork* $\geq 5*n + \max(5*nn, NB*(np0 + 1))$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{iceil}(neig, NPROW*NPCOL)*nn.$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j) + orfac*2*norm(A)\}$$

Variable definitions:

neig = number of eigenvectors requested,

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*),

nn = $\max(n, nb, 2)$,

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0,

np0 = *numroc*(*nn*, *nb*, 0, 0, NPROW),

mq0 = *numroc*($\max(neig, nb, 2)$, *nb*, 0, 0, NPCOL)

iceil(*x*, *y*) is a ScaLAPACK function returning $\text{ceiling}(x/y)$

If *lwork* is too small to guarantee orthogonality, *pssyevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible. Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

```
lwork ≥ max(lwork, 5*n + nsytrd_lwopt,
nsygst_lwopt), where
lwork, as defined previously, depends upon the number of
eigenvectors requested, and
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) +
(nps+3)*nps
nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb
anb = pjlaenv(desca(ctxt_), 3, p?sytttrd 'L',
0, 0, 0, 0)
sqnpc = int(sqrt(dble(NPROW * NPCOL)))
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
NB = desca(mb_)
np0 = numroc(n, nb, 0, 0, NPROW)
nq0 = numroc(n, nb, 0, 0, NPCOL)
numroc is a ScaLAPACK tool functions;
pjlaenv is a ScaLAPACK environmental inquiry function
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.
For large n, no extra workspace is needed, however the
biggest boost in performance comes for small n, so it is wise
to provide the extra workspace (typically less than a
Megabyte per process).
```

If $clustersize \geq n/\sqrt{NPROW*NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $clustersize = n-1$) `pstein` will perform no better than `stein` on a single processor.

For $clustersize = n/\sqrt{NPROW*NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW*NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*.

$liwork \geq 6*nnp$

Where:

$nnp = \max(n, NPROW*NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit,

If $jobz = 'V'$, and if $info = 0$, `sub(A)` contains the distributed matrix Z of eigenvectors. The eigenvectors are normalized as follows:

for $ibtype = 1$ or 2 , $Z^T * \text{sub}(B) * Z = I$;

for $ibtype = 3$, $Z^T * \text{inv}(\text{sub}(B)) * Z = I$.

	<p>If <code>jobz = 'N'</code>, then on exit the upper triangle (if <code>uplo='U'</code>) or the lower triangle (if <code>uplo='L'</code>) of <code>sub(A)</code>, including the diagonal, is destroyed.</p>
<code>b</code>	<p>On exit, if <code>info ≤ n</code>, the part of <code>sub(B)</code> containing the matrix is overwritten by the triangular factor <code>U</code> or <code>L</code> from the Cholesky factorization <code>sub(B) = U^T*U</code> or <code>sub(B) = L*L^T</code>.</p>
<code>m</code>	<p>(global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.</p>
<code>nz</code>	<p>(global) INTEGER.</p> <p>Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of <code>z</code> that are filled.</p> <p>If <code>jobz ≠ 'V'</code>, <code>nz</code> is not referenced.</p> <p>If <code>jobz = 'V'</code>, <code>nz = m</code> unless the user supplies insufficient space and <code>p?sygvx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in <code>z</code> (<code>m.le.descz(n_)</code>) and sufficient workspace to compute them. (See <code>lwork</code> below.) <code>p?sygvx</code> is always able to detect insufficient space without computation unless <code>range.eq. 'V'</code>.</p>
<code>w</code>	<p>(global)</p> <p>REAL for <code>pssygvx</code></p> <p>DOUBLE PRECISION for <code>pdsygvx</code>.</p> <p>Array, DIMENSION (<code>n</code>). On normal exit, the first <code>m</code> entries contain the selected eigenvalues in ascending order.</p>
<code>z</code>	<p>(local).</p> <p>REAL for <code>pssygvx</code></p> <p>DOUBLE PRECISION for <code>pdsygvx</code>.</p> <p>global dimension (<code>n, n</code>), local dimension (<code>lld_z, LOCc(jz+n-1)</code>).</p> <p>If <code>jobz = 'V'</code>, then on normal exit the first <code>m</code> columns of <code>z</code> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector</p>

fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
 If *jobz* = 'N', then z is not referenced.

work
 If *jobz*='N' *work*(1) = optimal amount of workspace required to compute eigenvalues efficiently
 If *jobz* = 'V' *work*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.
 If *range*='V', it is assumed that all eigenvectors may be required.

ifail
 (global) INTEGER.
 Array, DIMENSION (*n*).
ifail provides additional information when *info.ne.0*
 If (mod(*info*/16,2).ne.0) then *ifail*(1) indicates the order of the smallest minor which is not positive definite. If (mod(*info*,2).ne.0) on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.
 If neither of the above error conditions hold and *jobz* = 'V', then the first *m* elements of *ifail* are set to zero.

iclustr
 (global) INTEGER.
 Array, DIMENSION (2*NPROW*NPCOL). This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*).
 Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array.
 (*iclustr*(2*k).ne.0.and. *iclustr*(2*k+1).eq.0) if and only if *k* is the number of clusters *iclustr* is not referenced if *jobz* = 'N'.

gap
 (global)
 REAL for pssygvx
 DOUBLE PRECISION for pdsygvx.

Array, DIMENSION (NPROW*NPCOL). This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n)/gap(i)$, where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0:

If $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(\text{info}, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented p?sygvx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then p?stebz failed to compute eigenvalues.

If $(\text{mod}(\text{info}/16, 2) \neq 0)$, then *B* was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

p?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem.

Syntax

```
call pchegvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork,
lrwork, iwork, liwork, ifail, iclustr, gap, info)
```

```
call pzhegvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork,
lrwork, iwork, liwork, ifail, iclustr, gap, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \quad \text{sub}(A) * \text{sub}(B) * x = \lambda * x, \quad \text{or} \quad \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ and $\text{sub}(B)$ are assumed to be Hermitian and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \lambda * \text{sub}(B) * x$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \lambda * x$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \lambda * x$.
<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	(global). CHARACTER*1. Must be 'A' or 'V' or 'I'.

	<p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues in the interval: [<i>vl</i>, <i>vu</i>]</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i>.</p>
<i>uplo</i>	<p>(global). CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of sub(<i>A</i>) and sub(<i>B</i>);</p> <p>If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of sub(<i>A</i>) and sub(<i>B</i>).</p>
<i>n</i>	<p>(global). INTEGER.</p> <p>The order of the matrices sub(<i>A</i>) and sub(<i>B</i>) ($n \geq 0$).</p>
<i>a</i>	<p>(local)</p> <p>COMPLEX for pchegvx</p> <p>DOUBLE COMPLEX for pzhegvx.</p> <p>Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the <i>n</i>-by-<i>n</i> Hermitian distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix.</p>
<i>ia, ja</i>	<p>(global) INTEGER.</p> <p>The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, dimension (<i>dlen_</i>).</p> <p>The array descriptor for the distributed matrix <i>A</i>. If <i>desca(ctxt_)</i> is incorrect, p?hegvx cannot guarantee correct error reporting.</p>
<i>b</i>	<p>(local).</p> <p>COMPLEX for pchegvx</p> <p>DOUBLE COMPLEX for pzhegvx.</p>

	<p>Pointer into the local memory to an array of dimension $(lld_b, LOCC(jb+n-1))$. On entry, this array contains the local pieces of the n-by-n Hermitian distributed matrix $\text{sub}(B)$.</p> <p>If $uplo = 'U'$, the leading n-by-n upper triangular part of $\text{sub}(B)$ contains the upper triangular part of the matrix.</p> <p>If $uplo = 'L'$, the leading n-by-n lower triangular part of $\text{sub}(B)$ contains the lower triangular part of the matrix.</p>
<i>ib, jb</i>	<p>(global) INTEGER.</p> <p>The row and column indices in the global array b indicating the first row and the first column of the submatrix B, respectively.</p>
<i>descb</i>	<p>(global and local) INTEGER array, dimension $(dlen_)$.</p> <p>The array descriptor for the distributed matrix B. $descb(ctxt_)$ must be equal to $desca(ctxt_)$.</p>
<i>vl, vu</i>	<p>(global)</p> <p>REAL for <code>pchegvx</code> DOUBLE PRECISION for <code>pzhegvx</code>.</p> <p>If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>If $range = 'A'$ or $'I'$, vl and vu are not referenced.</p>
<i>il, iu</i>	<p>(global)</p> <p>INTEGER.</p> <p>If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint:</p> $il \geq 1, \min(il, n) \leq iu \leq n$ <p>If $range = 'A'$ or $'V'$, il and iu are not referenced.</p>
<i>abstol</i>	<p>(global)</p> <p>REAL for <code>pchegvx</code> DOUBLE PRECISION for <code>pzhegvx</code>.</p> <p>If $jobz='V'$, setting $abstol$ to <code>p?lamch(context, 'U')</code> yields the most orthogonal eigenvectors.</p> <p>The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to</p> $abstol + eps * \max(a , b),$

where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps**norm(T) will be used in its place, where norm(T) is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2*p?lamch('S')$ not zero. If this routine returns with $((mod(info,2).ne.0).or.* (mod(info/8,2).ne.0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to $2*p?lamch('S')$.

orfac

(global).

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol=orfac*norm(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0E-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global array *z* indicating the first row and the first column of the submatrix *z*, respectively.

descz

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work

(local)

COMPLEX for pchegvx

DOUBLE COMPLEX for pzhegvx.

Workspace array, dimension (*lwork*)

lwork

(local).

INTEGER. The dimension of the array *work*.

If only eigenvalues are requested:

$lwork \geq n + \max(NB*(np0 + 1), 3)$

If eigenvectors are requested:

$lwork \geq n + (np0 + mq0 + NB) * NB$
 with $nq0 = \text{numroc}(nn, NB, 0, 0, NPCOL)$.
 For optimal performance, greater workspace is needed, that is

$lwork \geq \max(lwork, n, nhetr_lwork, nhegst_lwork)$

where $lwork$ is as defined above, and

$nhetr_lwork = 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps;$

$nhegst_lwork = 2 * np0 * nb + nq0 * nb + nb * nb$

$nb = \text{desca}(mb_)$

$np0 = \text{numroc}(n, nb, 0, 0, NPROW)$

$nq0 = \text{numroc}(n, nb, 0, 0, NPCOL)$

$ictxt = \text{desca}(ctxt_)$

$anb = \text{pjlaenv}(ictxt, 3, 'p?hettrd', 'L', 0, 0, 0, 0)$

$sqnpc = \text{sqrt}(\text{dble}(NPROW * NPCOL))$

$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 * anb)$

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

$MYROW, MYCOL, NPROW$ and $NPCOL$ can be determined by

calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

rwork

(local)

REAL for `pchegvx`

DOUBLE PRECISION for `pzhgevx`.

Workspace array, DIMENSION ($lrwork$).

lrwork

(local) INTEGER. The dimension of the array *rwork*.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested ($jobz = 'N'$), then

$lrwork \geq 5 * nn + 4 * n$

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lrwork \geq 4*n + \max(5*nn, np0*mq0) + \text{iceil}(neig, \text{NPROW}*\text{NPCOL}) * nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lrwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j) + orfac * 2 * \text{norm}(A)\}$$

Variable definitions:

neig = number of eigenvectors requested;
nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);
nn = max(*n*, *nb*, 2);
desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0;
np0 = numroc(*nn*, *nb*, 0, 0, NPROW);
mq0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL);
iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*).

When *lrwork* is too small:

If *lwork* is too small to guarantee orthogonality, *p?hegvx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range*='V', *p?hegvx* does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow *p?hegvx* to compute the eigenvalues, *p?hegvx* will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If $clustersize > n/\sqrt{NPROW*NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) `p?stein` will perform no better than `?stein` on 1 processor.

For $clustersize = n/\sqrt{NPROW*NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW*NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `p_xerbla`.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*.

$liwork \geq 6*nnp$

Where: $nnp = \max(n, NPROW*NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p_xerbla`.

Output Parameters

a

On exit, if $jobz = 'V'$, then if $info = 0$, $sub(a)$ contains the distributed matrix Z of eigenvectors.

The eigenvectors are normalized as follows:

If $ibtype = 1$ or 2 , then $Z^H * sub(B) * Z = I$;

If $ibtype = 3$, then $Z^H * \text{inv}(\text{sub}(B)) * Z = I$.
 If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of $\text{sub}(A)$, including the diagonal, is destroyed.

b On exit, if $info \leq n$, the part of $\text{sub}(B)$ containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^H * U$, or $\text{sub}(B) = L * L^H$.

m (global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

nz (global) INTEGER. Total number of eigenvectors computed. $0 < nz < m$. The number of columns of z that are filled. If $jobz \neq 'V'$, nz is not referenced. If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and `p?hegvx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z (*m. le. descz(n_)*) and sufficient workspace to compute them. (See *lwork* below.) The routine `p?hegvx` is always able to detect insufficient space without computation unless $range = 'V'$.

w (global)
 REAL for `pchegvx`
 DOUBLE PRECISION for `pzhegvx`.
 Array, DIMENSION (n). On normal exit, the first m entries contain the selected eigenvalues in ascending order.

z (local).
 COMPLEX for `pchegvx`
 DOUBLE COMPLEX for `pzhegvx`.
 global dimension (n, n), local dimension ($lld_z, LOCC(jz+n-1)$).
 If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

	If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i>	On exit, <i>work</i> (1) returns the optimal amount of workspace.
<i>rwork</i>	On exit, <i>rwork</i> (1) contains the amount of workspace required for optimal efficiency If <i>jobz</i> ='N' <i>rwork</i> (1) = optimal amount of workspace required to compute eigenvalues efficiently If <i>jobz</i> ='V' <i>rwork</i> (1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality. If <i>range</i> ='V', it is assumed that all eigenvectors may be required when computing optimal workspace.
<i>ifail</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). <i>ifail</i> provides additional information when <i>info.ne.0</i> If (mod(<i>info</i> /16,2).ne.0), then <i>ifail</i> (1) indicates the order of the smallest minor which is not positive definite. If (mod(<i>info</i> ,2).ne.0) on exit, then <i>ifail</i> (1) contains the indices of the eigenvectors that failed to converge. If neither of the above error conditions are held, and <i>jobz</i> = 'V', then the first <i>m</i> elements of <i>ifail</i> are set to zero.
<i>iclustr</i>	(global) INTEGER. Array, DIMENSION (2*NPROW*NPCOL). This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see <i>lwork</i> , <i>orfac</i> and <i>info</i>). Eigenvectors corresponding to clusters of eigenvalues indexed <i>iclustr</i> (2*i-1) to <i>iclustr</i> (2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. <i>iclustr</i> () is a zero terminated array. (<i>iclustr</i> (2*k).ne.0.and. <i>iclustr</i> (2*k+1).eq.0) if and only if <i>k</i> is the number of clusters. <i>iclustr</i> is not referenced if <i>jobz</i> = 'N'.
<i>gap</i>	(global) REAL for pchegvx DOUBLE PRECISION for pzhegvx.

info

Array, DIMENSION (NPROW*NPCOL).

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n)/gap(i)$, where *C* is a small constant.

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0:

If $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(\text{info}, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented *p?sygvx* from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then *p?stebz* failed to compute eigenvalues.

If $(\text{mod}(\text{info}/16, 2) \neq 0)$, then *B* was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

ScaLAPACK Auxiliary and Utility Routines

7

This chapter describes the Intel® Math Kernel Library implementation of ScaLAPACK [Auxiliary Routines](#) and [Utility Functions and Routines](#). The library includes routines for both real and complex data.

NOTE. ScaLAPACK routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Routine naming conventions, mathematical notation, and matrix storage schemes used for ScaLAPACK auxiliary and utility routines are the same as described in previous chapters. Some routines and functions may have combined character codes, such as `sc` or `dz`. For example, the routine `pscsum1` uses a complex input array and returns a real value.

Auxiliary Routines

Table 7-1 ScaLAPACK Auxiliary Routines

Routine Name	Data Types	Description
<code>p_lacgv</code>	<code>c, z</code>	Conjugates a complex vector.
<code>p_?max1</code>	<code>c, z</code>	Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS <code>p_?amax</code> , but using the absolute value to the real part).
<code>?combamax1</code>	<code>c, z</code>	Finds the element with maximum real part absolute value and its corresponding global index.
<code>p_?sum1</code>	<code>sc, dz</code>	Forms the 1-norm of a complex vector similar to Level 1 PBLAS <code>p_?asum</code> , but using the true absolute value.
<code>p_?dbtrsv</code>	<code>s, d, c, z</code>	Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting. The routine is called by <code>p_?dbtrs</code> .
<code>p_?dttrsv</code>	<code>s, d, c, z</code>	Computes an <i>LU</i> factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by <code>p_?dttrs</code> .

Routine Name	Data Types	Description
p?gebd2	s, d, c, z	Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).
p?gehd2	s, d, c, z	Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).
p?gelq2	s, d, c, z	Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).
p?geql2	s, d, c, z	Computes a QL factorization of a general rectangular matrix (unblocked algorithm).
p?geqr2	s, d, c, z	Computes a QR factorization of a general rectangular matrix (unblocked algorithm).
p?gerq2	s, d, c, z	Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).
p?getf2	s, d, c, z	Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).
p?labrd	s, d, c, z	Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?lacon	s, d, c, z	Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.
p?laconsb	s, d	Looks for two consecutive small subdiagonal elements.
p?lACP2	s, d, c, z	Copies all or part of a distributed matrix to another distributed matrix.
p?lACP3	s, d	Copies from a global parallel array into a local replicated array or vice versa.

Routine Name	Data Types	Description
p?lacpy	<i>s, d, c, z</i>	Copies all or part of one two-dimensional array to another.
p?laevswp	<i>s, d, c, z</i>	Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.
p?lahrd	<i>s, d, c, z</i>	Reduces the first <i>nb</i> columns of a general rectangular matrix A so that elements below the k^{th} subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?laiect	<i>s, d, c, z</i>	Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).
p?lange	<i>s, d, c, z</i>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.
p?lanhs	<i>s, d, c, z</i>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.
p?lansy, p?lanhe	<i>s, d, c, z/c, z</i>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.
p?lantr	<i>s, d, c, z</i>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.
p?lapiv	<i>s, d, c, z</i>	Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.
p?laqge	<i>s, d, c, z</i>	Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ .
p?laqsy	<i>s, d, c, z</i>	Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ .

Routine Name	Data Types	Description
p?lared1d	s, d	Redistributes an array assuming that the input array <i>bycol</i> is distributed across rows and that all process columns contain the same copy of <i>bycol</i> .
p?lared2d	s, d	Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> .
p?larf	s, d, c, z	Applies an elementary reflector to a general rectangular matrix.
p?larfb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
p?larfc	c, z	Applies the conjugate transpose of an elementary reflector to a general matrix.
p?larfg	s, d, c, z	Generates an elementary reflector (Householder matrix).
p?larft	s, d, c, z	Forms the triangular vector T of a block reflector $H=I- VTV^H$
p?larz	s, d, c, z	Applies an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.
p?larzc	c, z	Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzt	s, d, c, z	Forms the triangular factor T of a block reflector $H=I- VTV^H$ as returned by p?tzrzf .
p?lascl	s, d, c, z	Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from} .
p?laset	s, d, c, z	Initializes the off-diagonal elements of a matrix to α and the diagonal elements to β .

Routine Name	Data Types	Description
p?lasmsub	s, d	Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.
p?lassq	s, d, c, z	Updates a sum of squares represented in scaled form.
p?laswp	s, d, c, z	Performs a series of row interchanges on a general rectangular matrix.
p?latra	s, d, c, z	Computes the trace of a general square distributed matrix.
p?latrd	s, d, c, z	Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.
p?latrz	s, d, c, z	Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.
p?lauu2	s, d, c, z	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices (local unblocked algorithm).
p?lauum	s, d, c, z	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices.
p?lawil	s, d	Forms the Wilkinson transform.
p?org2l/p?ung2l	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).
p?org2r/p?ung2r	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orgl2/p?ungl2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).
p?org2/p?ungr2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).

Routine Name	Data Types	Description
p?orm2l/p?unm2l	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).
p?orm2r/p?unm2r	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orml2/p?unml2	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).
p?ormr2/p?unmr2	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?pbtrsv	<i>s, d, c, z</i>	Solves a single triangular linear system via <code>frontsolve</code> or <code>backsolve</code> where the triangular matrix is a factor of a banded matrix computed by p?pbtrf .
p?pttrsv	<i>s, d, c, z</i>	Solves a single triangular linear system via <code>frontsolve</code> or <code>backsolve</code> where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf .
p?potf2	<i>s, d, c, z</i>	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).
p?rscl	<i>s, d, cs, zd</i>	Multiplies a vector by the reciprocal of a real scalar.
p?sygs2/p?hegs2	<i>s, d, c, z</i>	Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).
p?sytd2/p?hetd2	<i>s, d, c, z</i>	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).
p?trti2	<i>s, d, c, z</i>	Computes the inverse of a triangular matrix (local unblocked algorithm).

Routine Name	Data Types	Description
?lamsh	s, d	Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.
?laref	s, d	Applies Householder reflectors to matrices on either their rows or columns.
?lasorte	s, d	Sorts eigenpairs by real and complex data types.
?lasrt2	s, d	Sorts numbers in increasing or decreasing order.
?stein2	s, d	Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.
?dbtf2	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).
?dbtrf	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).
?dttrf	s, d, c, z	Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).
?dttrsv	s, d, c, z	Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf .
?pttrsv	s, d, c, z	Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the LDL^H factorization computed by ?pttrf .
?steqr2	s, d	Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

p?lacgv

Conjugates a complex vector.

Syntax

```
call pclacgv(n, x, ix, jx, descx, incx)
```

```
call pzlacgv(n, x, ix, jx, descx, incx)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine conjugates a complex vector `sub(x)` of length n , where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix:ix+n-1, jx)$ if $incx = 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of the distributed vector <code>sub(x)</code> .
<i>x</i>	(local). COMPLEX for <code>pclacgv</code> COMPLEX*16 for <code>pzlacgv</code> . Pointer into the local memory to an array of DIMENSION (<i>lld_x</i> , *). On entry the vector to be conjugated $x(i) = X(ix+(jx-1)*m_x+(i-1)*incx)$, $1 \leq i \leq n$.
<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of <code>sub(x)</code> .
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of <code>sub(x)</code> .
<i>descx</i>	(global and local) INTEGER. Array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. The global increment for the elements of <i>x</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	(local).
----------	----------

On exit, the conjugated vector.

p?max1

Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS p?amax, but using the absolute value to the real part).

Syntax

```
call p?max1(n, amax, indx, x, ix, jx, descx, incx)
```

```
call pzmax1(n, amax, indx, x, ix, jx, descx, incx)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the global index of the maximum element in absolute value of a distributed vector $\text{sub}(x)$. The global index is returned in `indx` and the value is returned in `amax`, where $\text{sub}(x)$ denotes $X(ix:ix+n-1, jx)$ if `incx` = 1, $X(ix, jx:jx+n-1)$ if `incx` = `m_x`.

Input Parameters

<code>n</code>	(global) pointer to INTEGER. The number of components of the distributed vector $\text{sub}(x)$. $n \geq 0$.
<code>x</code>	(local) COMPLEX for p?max1. COMPLEX*16 for pzmax1 Array containing the local pieces of a distributed matrix of dimension of at least $((jx-1)*m_x+ix+(n-1)*abs(incx))$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<code>ix</code>	(global) INTEGER. The row index in the global array x indicating the first row of $\text{sub}(x)$.
<code>jx</code>	(global) INTEGER. The column index in the global array x indicating the first column of $\text{sub}(x)$.
<code>descx</code>	(global and local) INTEGER. Array, DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix x .

incx (global) **INTEGER**. The global increment for the elements of *x*. Only two values of *incx* are supported in this version, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

amax (global output) pointer to **REAL**. The absolute value of the largest entry of the distributed vector *sub(x)* only in the scope of *sub(x)*.

indx (global output) pointer to **INTEGER**. The global index of the element of the distributed vector *sub(x)* whose real part has maximum absolute value.

?combamax1

Finds the element with maximum real part absolute value and its corresponding global index.

Syntax

```
call ccombamax1(v1, v2)
```

```
call zcombamax1(v1, v2)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine finds the element having maximum real part absolute value as well as its corresponding global index.

Input Parameters

v1 (local)
COMPLEX for `ccombamax1`
COMPLEX*16 for `zcombamax1` Array, **DIMENSION 2**. The first maximum absolute value element and its global index.
v1(1)=amax, v1(2)=indx.

v2 (local)
COMPLEX for `ccombamax1`
COMPLEX*16 for `zcombamax1`

Array, `DIMENSION 2`. The second maximum absolute value element and its global index. `v2(1)=amax`, `v2(2)=indx`.

Output Parameters

`v1` (local).
The first maximum absolute value element and its global index. `v1(1)=amax`, `v1(2)=indx`.

p?sum1

Forms the 1-norm of a complex vector similar to Level 1 PBLAS `p?asum`, but using the true absolute value.

Syntax

```
call pscsum1(n, asum, x, ix, jx, descx, incx)
call pdzsum1(n, asum, x, ix, jx, descx, incx)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine returns the sum of absolute values of a complex distributed vector `sub(x)` in `asum`, where `sub(x)` denotes `X(ix:ix+n-1, jx:jx)`, if `incx = 1`, `X(ix:ix, jx:jx+n-1)`, if `incx = m_x`.

Based on `p?asum` from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

Input Parameters

`n` (global) pointer to `INTEGER`. The number of components of the distributed vector `sub(x)`. $n \geq 0$.

`x` (local) `COMPLEX` for `pscsum1`
`COMPLEX*16` for `pdzsum1`.
Array containing the local pieces of a distributed matrix of dimension of at least $((jx-1)*m_x + ix + (n-1)*abs(incx))$. This array contains the entries of the distributed vector `sub(x)`.

<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of sub(<i>x</i>).
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of sub(<i>x</i>)
<i>descx</i>	(global and local) INTEGER. Array, DIMENSION 8. The array descriptor for the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. The global increment for the elements of <i>x</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> .

Output Parameters

<i>asum</i>	(local) Pointer to REAL. The sum of absolute values of the distributed vector sub(<i>x</i>) only in its scope.
-------------	---------------------------------------------------------------------------------------------------------------------

p?dbtrsv

Computes an LU factorization of a general triangular matrix with no pivoting. The routine is called by p?dbtrs.

Syntax

```
call psdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pddbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pcdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pzdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routines solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$ (for real flavors); $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$ (for complex flavors),

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Gaussian elimination code PD@ (dom_pre) BTRF and is stored in $A(1:n, ja:ja+n-1)$ and *af*. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter *trans*.

Routine `p?dbtrf` must be called first.

Input Parameters

uplo (global) CHARACTER.
If *uplo*='U', the upper triangle of $A(1:n, ja:ja+n-1)$ is stored,
if *uplo* = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

trans (global) CHARACTER.
If *trans* = 'N', solve with $A(1:n, ja:ja+n-1)$,
if *trans* = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$.

n (global) INTEGER. The order of the distributed submatrix A ; ($n \geq 0$).

bwl (global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.

bwu (global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.

nrhs (global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).

a (local).
REAL for psdbtrsv
DOUBLE PRECISION for pddbtrsv
COMPLEX for pcdbrsv
COMPLEX*16 for pzdbtrsv.
Pointer into the local memory to an array with first
DIMENSION $lld_a \geq (bwl+bwu+1)$ (stored in *desca*). On entry,
this array contains the local pieces of the n -by- n

	unsymmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). if 1d type (<i>dtype_a</i> = 501 or 502), <i>dlen</i> ≥ 7; if 2d type (<i>dtype_a</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdbtrsv DOUBLE PRECISION for pddbtrsv COMPLEX for pcdbtrsv COMPLEX*16 for pzdbtrsv. Pointer into the local memory to an array of local lead DIMENSION <i>lld_b</i> ≥ <i>nb</i> . On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). if 1d type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; if 2d type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping <i>B</i> to memory.
<i>laf</i>	(local) INTEGER. Size of user-input Auxiliary Filling space <i>af</i> . <i>laf</i> must be ≥ $nb * (bwl + bwu) + 6 * \max(bwl, bwu) * \max(bwl, bwu)$. If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local).

REAL for psdbtrsv
 DOUBLE PRECISION for pddbtrsv
 COMPLEX for pcdbtrsv
 COMPLEX*16 for pzdbtrsv.

Temporary workspace. This space may be overwritten in between calls to routines.

work must be the size given in *lwork*.

lwork

(local or global) INTEGER.

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

$lwork \geq \max(bw1, bwu) * nrhs$.

Output Parameters

a

(local).

This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.

b

On exit, this contains the local piece of the solutions distributed matrix *x*.

af

(local).

REAL for psdbtrsv
 DOUBLE PRECISION for pddbtrsv
 COMPLEX for pcdbtrsv
 COMPLEX*16 for pzdbtrsv.

Auxiliary Filling Space. Filling is created during the factorization routine *p?dbtrf* and this is stored in *af*. If a linear system is to be solved using *p?dbtrf* after the factorization routine, *af* must not be altered after the factorization.

work

On exit, *work*(1) contains the minimal *lwork*.

info

(local).

INTEGER. If *info* = 0, the execution is successful.

< 0: If the i -th argument is an array and the j -entry had an illegal value, then $info = - (i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?dttrsv

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by p?dttrs.

Syntax

```
call psdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pddttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pcdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pzdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
laf, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine solves a tridiagonal triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs)$ or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$ for real flavors; $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a tridiagonal matrix factor produced by the Gaussian elimination code `PS@ (dom_pre)TTRF` and is stored in $A(1:n, ja:ja+n-1)$ and af .

The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to $uplo$, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter $trans$.

Routine `p?dttrf` must be called first.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER. If <i>uplo</i>='U', the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <i>uplo</i> = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.</p>
<i>trans</i>	<p>(global) CHARACTER. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$, if <i>trans</i> = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$.</p>
<i>n</i>	<p>(global) INTEGER. The order of the distributed submatrix A; ($n \geq 0$).</p>
<i>nrhs</i>	<p>(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix $B(ib:ib+n-1, 1:nrhs)$. ($nrhs \geq 0$).</p>
<i>dl</i>	<p>(local). REAL for psdttrsv DOUBLE PRECISION for pddttrsv COMPLEX for pcdttrsv COMPLEX*16 for pzdttrsv. Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, <i>dl</i>(1) is not referenced, and <i>dl</i> must be aligned with <i>d</i>. Must be of size $\geq \text{desca}(nb_)$.</p>
<i>d</i>	<p>(local). REAL for psdttrsv DOUBLE PRECISION for pddttrsv COMPLEX for pcdttrsv COMPLEX*16 for pzdttrsv. Pointer to local part of global vector storing the main diagonal of the matrix.</p>
<i>du</i>	<p>(local). REAL for psdttrsv DOUBLE PRECISION for pddttrsv</p>

	<p>COMPLEX for pcdttrsv COMPLEX*16 for pzdttrsv. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du(n)$ is not referenced, and du must be aligned with d.</p>
ja	<p>(global) INTEGER. The index in the global array a that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).</p>
$desca$	<p>(global and local). INTEGER array of DIMENSION ($dlen_$). if 1d type ($dtype_a = 501$ or 502), $dlen \geq 7$; if 2d type ($dtype_a = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix A. Contains information of mapping of A to memory.</p>
b	<p>(local) REAL for psdttrsv DOUBLE PRECISION for pddttrsv COMPLEX for pcdttrsv COMPLEX*16 for pzdttrsv. Pointer into the local memory to an array of local lead DIMENSION $lld_b \geq nb$. On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1$:$nrhs)$.</p>
ib	<p>(global). INTEGER. The row index in the global array b that points to the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).</p>
$descb$	<p>(global and local). INTEGER array of DIMENSION ($dlen_$). if 1d type ($dtype_b = 502$), $dlen \geq 7$; if 2d type ($dtype_b = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix B. Contains information of mapping B to memory.</p>
laf	<p>(local). INTEGER. Size of user-input Auxiliary Filling space af.</p>

laf must be $\geq 2*(nb+2)$. If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*(1).

work (local).
 REAL for psdttrsv
 DOUBLE PRECISION for pddttrsv
 COMPLEX for pcdttrsv
 COMPLEX*16 for pzdttrsv.
 Temporary workspace. This space may be overwritten in between calls to routines.
work must be the size given in *lwork*.

lwork (local or global).INTEGER.
 Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.
 $lwork \geq 10*npcol+4*nrhs$.

Output Parameters

dl (local).
 On exit, this array contains information containing the factors of the matrix.

d On exit, this array contains information containing the factors of the matrix. Must be of size $\geq desca(nb_)$.

b On exit, this contains the local piece of the solutions distributed matrix X.

af (local).
 REAL for psdttrsv
 DOUBLE PRECISION for pddttrsv
 COMPLEX for pcdttrsv
 COMPLEX*16 for pzdttrsv.
 Auxiliary Filling Space. Filling is created during the factorization routine p?dttrf and this is stored in *af*. If a linear system is to be solved using p?dttrs after the factorization routine, *af* must not be altered after the factorization.

work On exit, *work*(1) contains the minimal *lwork*.

info (local). INTEGER.
 If *info*=0, the execution is successful.
 if *info*< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?gebd2

Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).

Syntax

```
call psgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine reduces a real/complex general *m*-by-*n* distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form *B* by an orthogonal/unitary transformation:
 $Q^* \text{sub}(A) P = B$.

If $m \geq n$, *B* is the upper bidiagonal; if $m < n$, *B* is the lower bidiagonal.

Input Parameters

m (global) INTEGER.
 The number of rows of the distributed submatrix $\text{sub}(A)$.
 ($m \geq 0$).

n (global) INTEGER.
 The order of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

a (local).
 REAL for psgebd2

DOUBLE PRECISION for pdgebd2
 COMPLEX for pcgebd2
 COMPLEX*16 for pzgebd2.
 Pointer into the local memory to an array of
 DIMENSION(*lld_a*, *LOCc(ja+n-1)*).
 On entry, this array contains the local pieces of the general
 distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the global
 array *a* indicating the first row and the first column of the
 submatrix *A*, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The
 array descriptor for the distributed matrix *A*.

work (local).
 REAL for psgebd2
 DOUBLE PRECISION for pdgebd2
 COMPLEX for pcgebd2
 COMPLEX*16 for pzgebd2.
 This is a workspace array of DIMENSION (*lwork*).

lwork (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq$
 $\max(mpa0, nqa0)$,
 where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia-1, nb)$,
 $iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb, mycol, csrc_a, npcol)$,
 $mpa0 = \text{numroc}(m+iroffa, nb, myrow, iarow,$
 $nprow)$,
 $nqa0 = \text{numroc}(n+icoffa, nb, mycol, iacol,$
 $npcol)$.
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*,
mycol, *nprow*, and *npcol* can be determined by calling the
 subroutine *blacs_gridinfo*.
 If *lwork* = -1, then *lwork* is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by *p_xerbla*.

Output Parameters

<i>a</i>	<p>(local).</p> <p>On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array <i>tauq</i>, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <i>taup</i>, represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array <i>tauq</i>, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array <i>taup</i>, represent the orthogonal matrix P as a product of elementary reflectors. See <i>Applications Notes</i> below.</p>
<i>d</i>	<p>(local)</p> <p>REAL for psgebd2 DOUBLE PRECISION for pdgebd2 COMPLEX for pcgebd2 COMPLEX*16 for pzgebd2.</p> <p>Array, DIMENSION $LOCc(ja+\min(m,n)-1)$ if $m \geq n$; $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B: $d(i) = a(i, i)$. <i>d</i> is tied to the distributed matrix A.</p>
<i>e</i>	<p>(local)</p> <p>REAL for psgebd2 DOUBLE PRECISION for pdgebd2 COMPLEX for pcgebd2 COMPLEX*16 for pzgebd2.</p> <p>Array, DIMENSION $LOCc(ja+\min(m,n)-1)$ if $m \geq n$; $LOCr(ia+\min(m,n)-2)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B:</p> <p>if $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$. <i>e</i> is tied to the distributed matrix A.</p>

tauq (local).
 REAL for psgebd2
 DOUBLE PRECISION for pdgebd2
 COMPLEX for pcgebd2
 COMPLEX*16 for pzgebd2.
 Array, DIMENSION $LOCc(ja+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . *tauq* is tied to the distributed matrix A .

taup (local).
 REAL for psgebd2
 DOUBLE PRECISION for pdgebd2
 COMPLEX for pcgebd2
 COMPLEX*16 for pzgebd2.
 Array, DIMENSION $LOCr(ia+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix P . *taup* is tied to the distributed matrix A .

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local)
 INTEGER.
 If *info* = 0, the execution is successful.
 if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (i*100+j),
 if the *i*-th argument is a scalar and had an illegal value,
 then *info* = -i.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1)*H(2)*\dots*H(n), \text{ and } P = G(1)*G(2)*\dots*G(n-1)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_q v v', \text{ and } G(i) = I - \tau_p u u',$$

where τ_q and τ_p are real/complex scalars, and v and u are real/complex vectors. $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i-ia+m-1, a+i-1);$
 $u(1:i) = 0, u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1);$
 $tauq$ is stored in $TAUQ(ja+i-1)$ and $taup$ in $TAUP(ia+i-1).$

If $m < n$,

$v(1:i) = 0, v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i+1: ia+m-1, ja+i-1);$
 $u(1:i-1) = 0, u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1);$
 $tauq$ is stored in $TAUQ(ja+i-1)$ and $taup$ in $TAUP(ia+i-1).$

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples:

$$\begin{array}{l}
 m = 6 \text{ and } n = 5 (m > n) : \\
 \begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}
 \end{array}
 \qquad
 \begin{array}{l}
 m = 5 \text{ and } n = 6 (m < n) : \\
 \begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}
 \end{array}$$

where d and e denote diagonal and off-diagonal elements of B , vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

p?gehd2

Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).

Syntax

```
call psgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine reduces a real/complex general distributed matrix $\text{sub}(A)$ to upper Hessenberg form H by an orthogonal/unitary similarity transformation: $Q' * \text{sub}(A) * Q = H$, where $\text{sub}(A) = A(\text{ia}+n-1 : \text{ia}+n-1, \text{ja}+n-1 : \text{ja}+n-1)$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed submatrix A . ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. It is assumed that $\text{sub}(A)$ is already upper triangular in rows $\text{ia}:\text{ia}+\text{ilo}-2$ and $\text{ia}+\text{ihi}:\text{ia}+n-1$ and columns $\text{ja}:\text{ja}+\text{jlo}-2$ and $\text{ja}+\text{jhi}:\text{ja}+n-1$. See <i>Application Notes</i> for further information. If $n \geq 0, 1 \leq \text{ilo} \leq \text{ihi} \leq n$; otherwise set $\text{ilo} = 1, \text{ihi} = n$.
<i>a</i>	(local). REAL for psgehd2 DOUBLE PRECISION for pdgehd2 COMPLEX for pcgehd2 COMPLEX*16 for pzgehd2. Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOcc(ja+n-1))</code> . On entry, this array contains the local pieces of the n -by- n general distributed matrix $\text{sub}(A)$ to be reduced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix A .
<i>work</i>	(local). REAL for psgehd2 DOUBLE PRECISION for pdgehd2 COMPLEX for pcgehd2 COMPLEX*16 for pzgehd2. This is a workspace array of <code>DIMENSION(lwork)</code> .
<i>lwork</i>	(local or global). INTEGER. The dimension of the array <i>work</i> .

lwork is local input and must be at least $lwork \geq nb + \max(npa0, nb)$, where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$, $npa0 = \text{numroc}(ihi+iroffa, nb, myrow, iarow, nprow)$.

indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pserbla*.

Output Parameters

<i>a</i>	(local). On exit, the upper triangle and the first subdiagonal of sub(<i>A</i>) are overwritten with the upper Hessenberg matrix <i>H</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors. (see <i>Application Notes</i> below).
<i>tau</i>	(local). REAL for <i>psgehd2</i> DOUBLE PRECISION for <i>pdgehd2</i> COMPLEX for <i>pcgehd2</i> COMPLEX*16 for <i>pzgehd2</i> . Array, DIMENSION <i>LOCc</i> (<i>ja+n-2</i>) The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). Elements <i>ja:ja+ilo-2</i> and <i>ja+ihi:ja+n-2</i> of <i>tau</i> are set to zero. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local).INTEGER. If <i>info</i> = 0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo)*H(ilo+1)*...*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i)=0$, $v(i+1)=1$ and $v(ihi+1:n)=0$; $v(i+2:ihi)$ is stored on exit in $A(ia+ilo+i:ia+ihi-1, ia+ilo+i-2)$, and τ in $\tau(ja+ilo+i-2)$.

The contents of $A(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ & a & h & h & h & h & a \\ & h & h & h & h & h & h \\ & v2 & h & h & h & h & h \\ & v2 & v3 & h & h & h & h \\ & v2 & v3 & v4 & h & h & h \\ & & & & & & a \end{bmatrix}$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?gelq2

Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes an LQ factorization of a real/complex distributed m -by- n matrix `sub(A)`
 $= A(ia:ia+m-1, ja:ja+n-1) = L^*Q$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix <code>sub(A)</code> . ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix <code>sub(A)</code> . ($n \geq 0$).
<i>a</i>	(local). REAL for <code>psgelq2</code> DOUBLE PRECISION for <code>pdgelq2</code> COMPLEX for <code>pcgelq2</code> COMPLEX*16 for <code>pzgelq2</code> . Pointer into the local memory to an array of DIMENSION(<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). On entry, this array contains the local pieces of the m -by- n distributed matrix <code>sub(A)</code> which is to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for <code>psgelq2</code> DOUBLE PRECISION for <code>pdgelq2</code> COMPLEX for <code>pcgelq2</code> COMPLEX*16 for <code>pzgelq2</code> . This is a workspace array of DIMENSION (<code>lwork</code>).
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> .

lwork is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$,

where $irow = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,

$iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$,

$mp0 = \text{numroc}(m+irow, mb_a, myrow, iarow, nprow)$,

$nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcot)$,

indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcot$ can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

(local).

On exit, the elements on and below the diagonal of sub(*A*) contain the m by $\min(m, n)$ lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau

(local).

REAL for `psgelq2`

DOUBLE PRECISION for `pdgelq2`

COMPLEX for `pcgelq2`

COMPLEX*16 for `pzgelq2`.

Array, DIMENSION $LOCr(ia+\min(m, n)-1)$. This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local).INTEGER. If *info* = 0, the execution is successful. if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia+k-1) * H(ia+k-2) * \dots * H(ia)$ for real flavors, $Q = (H(ia+k-1))^H * (H(ia+k-2))^H \dots * (H(ia))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau v v'$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ (for real flavors) or $\text{conjg}(v(i+1:n))$ (for complex flavors) is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$, and τ in $TAU(ia+i-1)$.

p?gseq12

Computes a QL factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes a QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$.

Input Parameters

<i>m</i>	<p>(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).</p>
<i>n</i>	<p>(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).</p>
<i>a</i>	<p>(local). REAL for psgeql2 DOUBLE PRECISION for pdgeql2 COMPLEX for pcgeql2 COMPLEX*16 for pzgeql2. Pointer into the local memory to an array of DIMENSION ($lld_a, LOCC(ja+n-1)$). On entry, this array contains the local pieces of the m-by-n distributed matrix $\text{sub}(A)$ which is to be factored.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix <i>A</i>.</p>
<i>work</i>	<p>(local). REAL for psgeql2 DOUBLE PRECISION for pdgeql2 COMPLEX for pcgeql2 COMPLEX*16 for pzgeql2. This is a workspace array of DIMENSION (<i>lwork</i>).</p>
<i>lwork</i>	<p>(local or global) INTEGER. The dimension of the array <i>work</i>. <i>lwork</i> is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $irow = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nrow)$,</p>

`iacol = indxg2p(ja, nb_a, mycol, csrc_a, npc0l),`
`mp0 = numroc(m+iroff, mb_a, myrow, iarow, nprow),`
`nq0 = numroc(n+icoff, nb_a, mycol, iacol, npc0l),`
`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`,
`mycol`, `nprow`, and `npc0l` can be determined by calling the
subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by `pserbla`.

Output Parameters

<code>a</code>	<p>(local).</p> <p>On exit,</p> <p>if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n-by-n lower triangular matrix L;</p> <p>if $m \leq n$, the elements on and below the $(n-m)$-th superdiagonal contain the m-by-n lower trapezoidal matrix L; the remaining elements, with the array <code>tau</code>, represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).</p>
<code>tau</code>	<p>(local).</p> <p>REAL for <code>psgeql2</code> DOUBLE PRECISION for <code>pdgeql2</code> COMPLEX for <code>pcgeql2</code> COMPLEX*16 for <code>pzgeql2</code>.</p> <p>Array, DIMENSION <code>LOCc(ja+n-1)</code>. This array contains the scalar factors of the elementary reflectors. <code>tau</code> is tied to the distributed matrix A.</p>
<code>work</code>	On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local). INTEGER.

If $info = 0$, the execution is successful. If $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = - (i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja)$, where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau v v'$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in $TAU(ja+n-k+i-1)$.

p?geqr2

Computes a QR factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes a QR factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * R$.

Input Parameters

m (global). INTEGER.

	The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for psgeqr2 DOUBLE PRECISION for pdgeqr2 COMPLEX for pcgeqr2 COMPLEX*16 for pzgeqr2. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)). On entry, this array contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix $\text{sub}(A)$ which is to be factored.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for psgeqr2 DOUBLE PRECISION for pdgeqr2 COMPLEX for pcgeqr2 COMPLEX*16 for pzgeqr2. This is a workspace array of DIMENSION (<i>lwork</i>).
<i>lwork</i>	(local or global). INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npc0)$, $mp0 = \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npc0)$.

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	<p>(local).</p> <p>On exit, the elements on and above the diagonal of sub(<i>A</i>) contain the $\min(m,n)$ by n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array <code>tau</code>, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).</p>
<code>tau</code>	<p>(local).</p> <p>REAL for <code>psgeqr2</code> DOUBLE PRECISION for <code>pdgeqr2</code> COMPLEX for <code>pcgeqr2</code> COMPLEX*16 for <code>pzgeqr2</code>.</p> <p>Array, DIMENSION <code>LOCc(ja+min(m,n)-1)</code>. This array contains the scalar factors of the elementary reflectors. <code>tau</code> is tied to the distributed matrix <i>A</i>.</p>
<code>work</code>	<p>On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code>.</p>
<code>info</code>	<p>(local). INTEGER.</p> <p>If <code>info = 0</code>, the execution is successful. if <code>info < 0</code>: If the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <code>info = - (i*100+j)</code>, if the <i>i</i>-th argument is a scalar and had an illegal value, then <code>info = -i</code>.</p>

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * . . . * H(ja+k-1), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(j) = I - \tau v v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ in $TAU(ja+i-1)$.

p?gerq2

Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgqrq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgqrq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgqrq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgqrq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes an RQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R^*Q$.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). REAL for psgqrq2 DOUBLE PRECISION for pdgqrq2 COMPLEX for pcgqrq2 COMPLEX*16 for pzgqrq2.

Pointer into the local memory to an array of DIMENSION
 $(lld_a, LOCC(ja+n-1))$.
 On entry, this array contains the local pieces of the m -by- n
 distributed matrix $sub(A)$ which is to be factored.

ia, ja (global) INTEGER. The row and column indices in the global
 array *a* indicating the first row and the first column of the
 submatrix *A*, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The
 array descriptor for the distributed matrix *A*.

work (local).
 REAL for psgqrq2
 DOUBLE PRECISION for pdgqrq2
 COMPLEX for pcgqrq2
 COMPLEX*16 for pzgqrq2.
 This is a workspace array of DIMENSION (*lwork*).

lwork (local or global). INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$, where
 $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$,
 $mp0 = \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcot)$,
 indxg2p and numroc are ScaLAPACK tool functions; *myrow*,
mycol, *nprow*, and *npcot* can be determined by calling the
 subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by `pxerbla`.

Output Parameters

a (local).
 On exit,

if $m \leq n$, the upper triangle of $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ;
 if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau (local).
 REAL for psgerq2
 DOUBLE PRECISION for pdgerq2
 COMPLEX for pcgerq2
 COMPLEX*16 for pzgerq2.
 Array, DIMENSION $LOCr(ia+m-1)$. This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix A .

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local). INTEGER.
 If *info* = 0, the execution is successful.
 if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1)$ for real flavors,

$Q = (H(ia))^H * (H(ia+1))^H * \dots * (H(ia+k-1))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$,

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ for real flavors or $\text{conjg}(v(1:n-k+i-1))$ for complex flavors is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in $TAU(ia+m-k+i-1)$.

p?getf2

Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).

Syntax

```
call psgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pdgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pcgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pzgetf2(m, n, a, ia, ja, desca, ipiv, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes an LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using partial pivoting with row interchanges.

The factorization has the form $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($nb_a - \text{mod}(ja-1, nb_a) \geq n \geq 0$).
a	(local). REAL for psgetf2 DOUBLE PRECISION for pdgetf2 COMPLEX for pcgetf2 COMPLEX*16 for pzgetf2.

Pointer into the local memory to an array of

`DIMENSION(11d_a, LOCc(ja+n-1))`.

On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.

ia, ja

(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca

(global and local) INTEGER array, `DIMENSION(dlen_)`. The array descriptor for the distributed matrix *A*.

Output Parameters

ipiv

(local). INTEGER.

Array, `DIMENSION(LOCr(m_a) + mb_a)`. This array contains the pivoting information. *ipiv*(*i*) -> The global row that local row *i* was swapped with. This array is tied to the distributed matrix *A*.

info

(local). INTEGER.

If *info* = 0: successful exit.

If *info* < 0:

- if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$,
- if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0: If *info* = *k*, $u(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor *u* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?labrd

Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .

Syntax

```
call pslabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

```
call pdlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

```
call pclabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

```
call pzlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine reduces the first nb rows and columns of a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form by an orthogonal/unitary transformation $Q'^* A * P$, and returns the matrices X and Y necessary to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $m \geq n$, $\text{sub}(A)$ is reduced to upper bidiagonal form; if $m < n$, $\text{sub}(A)$ is reduced to lower bidiagonal form.

This is an auxiliary routine called by `p?gebrd`.

Input Parameters

m

(global). INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

<i>n</i>	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>nb</i>	(global) INTEGER. The number of leading rows and columns of $\text{sub}(A)$ to be reduced.
<i>a</i>	(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd. Pointer into the local memory to an array of $\text{DIMENSION}(lld_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, $\text{DIMENSION}(dlen_)$. The array descriptor for the distributed matrix A.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array, $\text{DIMENSION}(dlen_)$. The array descriptor for the distributed matrix X.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the global array <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array, $\text{DIMENSION}(dlen_)$. The array descriptor for the distributed matrix Y.
<i>work</i>	(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd Workspace array, $\text{DIMENSION}(lwork)$

$lwork \geq nb_a + nq$,
 with $nq = \text{numroc}(n + \text{mod}(ia-1, nb_y), nb_y, mycol, iacol, npcol)$
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$
 indxg2p and numroc are ScaLAPACK tool functions; $myrow$,
 $mycol$, $nprow$, and $npcol$ can be determined by calling the
 subroutine `blacs_gridinfo`.

Output Parameters

a

(local)

On exit, the first nb rows and columns of the matrix are overwritten; the rest of the distributed matrix $\text{sub}(A)$ is unchanged.

If $m \geq n$, elements on and below the diagonal in the first nb columns, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first nb rows, with the array taup , represent the orthogonal/unitary matrix P as a product of elementary reflectors.

If $m < n$, elements below the diagonal in the first nb columns, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first nb rows, with the array taup , represent the orthogonal/unitary matrix P as a product of elementary reflectors. See *Application Notes* below.

d

(local).

REAL for `pslabrd`

DOUBLE PRECISION for `pdlabrd`

COMPLEX for `pclabrd`

COMPLEX*16 for `pzlabrd`

Array, DIMENSION $LOCr(ia + \min(m, n) - 1)$ if $m \geq n$;
 $LOCc(ja + \min(m, n) - 1)$ otherwise. The distributed diagonal
 elements of the bidiagonal distributed matrix B :

$d(i) = A(ia+i-1, ja+i-1)$.

d is tied to the distributed matrix A .

<i>e</i>	<p>(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd</p> <p>Array, DIMENSION $LOCr(ia+\min(m,n)-1)$ if $m \geq n$; $LOCc(ja+\min(m,n)-2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix <i>B</i>:</p> <p>if $m \geq n$, $E(i) = A(ia+i-1, ja+i)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $E(i) = A(ia+i, ja+i-1)$ for $i = 1, 2, \dots, m-1$. <i>e</i> is tied to the distributed matrix <i>A</i>.</p>
<i>tauq, taup</i>	<p>(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd</p> <p>Array DIMENSION $LOCc(ja+\min(m, n)-1)$ for <i>tauq</i>, DIMENSION $LOCr(ia+\min(m, n)-1)$ for <i>taup</i>. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix <i>Q</i> for <i>tauq</i>, <i>P</i> for <i>taup</i>. <i>tauq</i> and <i>taup</i> are tied to the distributed matrix <i>A</i>. See <i>Application Notes</i> below.</p>
<i>x</i>	<p>(local) REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd</p> <p>Pointer into the local memory to an array of DIMENSION (lld_x, nb). On exit, the local pieces of the distributed <i>m</i>-by-<i>nb</i> matrix $X(ix:ix+m-1, jx:jx+nb-1)$ required to update the unreduced part of sub(<i>A</i>).</p>
<i>y</i>	<p>(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd</p>

COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd
 Pointer into the local memory to an array of DIMENSION
 (*lld_y*, *nb*). On exit, the local pieces of the distributed
n-by-*nb* matrix $Y(iy:iy+n-1, jy:jy+nb-1)$ required to
 update the unreduced part of sub(*A*).

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

$$Q = H(1)*H(2)*\dots*H(nb), \text{ and } P = G(1)*G(2)*\dots*G(nb)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{uq} v v', \text{ and } G(i) = I - \tau_{up} u u',$$

where τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors.

If $m \geq n$, $v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit
 in $A(ia+i-1, ja+i:ja+n-1)$; τ_{uq} is stored in $TAUQ(ja+i-1)$ and τ_{up} in $TAUP(ia+i-1)$.

If $m < n$, $v(1:i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in
 $A(ia+i-1, ja+i:ja+n-1)$; τ_{uq} is stored in $TAUQ(ja+i-1)$ and τ_{up} in $TAUP(ia+i-1)$. The
 elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U'
 which are necessary, with X and Y , to apply the transformation to the unreduced part of the
 matrix, using a block update of the form: $\text{sub}(A) := \text{sub}(A) - V*Y' - X*U'$. The contents
 of $\text{sub}(A)$ on exit are illustrated by the following examples with $nb = 2$:

$m = 6$ and $n = 5 (m > n)$:

$$\begin{bmatrix} 1 & 1 & u1 & u1 & u1 \\ v1 & 1 & 1 & u2 & u2 \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

$m = 5$ and $n = 6 (m < n)$:

$$\begin{bmatrix} 1 & u1 & u1 & u1 & u1 & u1 \\ 1 & 1 & u2 & u2 & u2 & u2 \\ v1 & 1 & a & a & a & a \\ v1 & v2 & a & a & a & a \\ v1 & v2 & a & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix which is unchanged, vi denotes an element
 of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

p?lacon

Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

```
call pslacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pdlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pclacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pzlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine estimates the 1-norm of a square, real/unitary distributed matrix A . Reverse communication is used for evaluating matrix-vector products. x and v are aligned with the distributed matrix A , this information is implicitly contained within iv , ix , $descv$, and $descx$.

Input Parameters

n	(global).INTEGER. The length of the distributed vectors v and x . $n \geq 0$.
v	(local). REAL for pslacon DOUBLE PRECISION for pdlacon COMPLEX for pclacon COMPLEX*16 for pzlacon. Pointer into the local memory to an array of DIMENSION $LOCr(n+\text{mod}(iv-1, mb_v))$. On the final return, $v = a*w$, where $est = \text{norm}(v)/\text{norm}(w)$ (w is not returned).
iv, jv	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix V , respectively.
$descv$	(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix V .
x	(local).

```

REAL for pslacon
DOUBLE PRECISION for pdlacon
COMPLEX for pclacon
COMPLEX*16 for pzlacon.
Pointer into the local memory to an array of DIMENSION
LOCr(n+mod(ix-1, mb_x)).
ix, jx (global) INTEGER. The row and column indices in the global
array x indicating the first row and the first column of the
submatrix x, respectively.
descx (global and local) INTEGER array, DIMENSION (dlen_). The
array descriptor for the distributed matrix X.
isgn (local). INTEGER.
Array, DIMENSION LOCr(n+mod(ix-1, mb_x)). isgn is
aligned with x and v.
kase (local). INTEGER.
On the initial call to p?lacon, kase should be 0.

```

Output Parameters

```

x (local).
On an intermediate return, X should be overwritten by  $A^*X$ ,
if kase=1,  $A' * X$ , if kase=2,
p?lacon must be re-called with all the other parameters
unchanged.
est (global). REAL for single precision flavors
DOUBLE PRECISION for double precision flavors
kase (local)
INTEGER. On an intermediate return, kase is 1 or 2,
indicating whether x should be overwritten by  $A^*X$ , or  $A' * X$ .
On the final return from p?lacon, kase is again 0.

```

p?laconsb

Looks for two consecutive small subdiagonal elements.

Syntax

```
call pslaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
call pdlaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift *QR* iteration given by *h44*, *h33*, and *h43h34* to see if this process makes a subdiagonal negligible.

Input Parameters

<i>a</i>	(global). REAL for pslaconsb DOUBLE PRECISION for pdlaconsb Array, DIMENSION (<i>desca</i> (<i>lld_</i>),*). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER. Array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>i</i>	(global) INTEGER. The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>l</i>	(global) INTEGER. The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>h44, h33, h43h34</i>	(global). REAL for pslaconsb DOUBLE PRECISION for pdlaconsb These three values are for the double shift <i>QR</i> iteration.
<i>lwork</i>	(global) INTEGER.

This must be at least $7 * \text{ceil}(\text{ceil}((i-1)/hbl) / \text{lcm}(nprow, npcold))$. Here lcm is least common multiple and $nprow \times npcold$ is the logical grid size.

Output Parameters

<i>m</i>	(global). On exit, this yields the starting location of the <i>QR</i> double shift. This will satisfy: $1 \leq m \leq i-2$.
<i>buf</i>	(local). REAL for <i>pslaconsb</i> DOUBLE PRECISION for <i>pdlaconsb</i> Array of size <i>lwork</i> .
<i>lwork</i>	(global). On exit, <i>lwork</i> is the size of the work buffer.

p?lacp2

Copies all or part of a distributed matrix to another distributed matrix.

Syntax

```
call pslacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, *p?lacp2* performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, a:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

p?lacp2 requires that only dimension of the matrix operands is distributed.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied:</p> <p>= 'U': Upper triangular part is copied; the strictly lower triangular part of $\text{sub}(A)$ is not referenced;</p> <p>= 'L': Lower triangular part is copied; the strictly upper triangular part of $\text{sub}(A)$ is not referenced.</p> <p>Otherwise: all of the matrix $\text{sub}(A)$ is copied.</p>
<i>m</i>	<p>(global) INTEGER.</p> <p>The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).</p>
<i>n</i>	<p>(global) INTEGER.</p> <p>The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).</p>
<i>a</i>	<p>(local).</p> <p>REAL for pslacp2 DOUBLE PRECISION for pdlacp2 COMPLEX for pclacp2 COMPLEX*16 for pzlacp2.</p> <p>Pointer into the local memory to an array of $\text{DIMENSION}(\text{lld_a}, \text{LOC}(ja+n-1))$.</p> <p>On entry, this array contains the local pieces of the m-by-n distributed matrix $\text{sub}(A)$.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of $\text{sub}(A)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, $\text{DIMENSION}(\text{dlen_})$. The array descriptor for the distributed matrix A.</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of $\text{sub}(B)$, respectively.</p>
<i>descb</i>	<p>(global and local) INTEGER array, $\text{DIMENSION}(\text{dlen_})$. The array descriptor for the distributed matrix B.</p>

Output Parameters

b (local).
 REAL for pslacp2
 DOUBLE PRECISION for pdlacp2
 COMPLEX for pclacp2
 COMPLEX*16 for pzlacp2.
 Pointer into the local memory to an array of DIMENSION
 (*lld_b*, *LOCc(jb+n-1)*). This array contains on exit the local
 pieces of the distributed matrix sub(*B*) set as follows:
 if *uplo* = 'U', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$,
 $1 \leq i \leq j, 1 \leq j \leq n$;
 if *uplo* = 'L', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$,
 $j \leq i \leq m, 1 \leq j \leq n$;
 otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 \leq i$
 $\leq m, 1 \leq j \leq n$.

p?lacp3

Copies from a global parallel array into a local replicated array or vice versa.

Syntax

```
call pslacp3(m, i, a, desca, b, ldb, ii, jj, rev)
```

```
call pdlacp3(m, i, a, desca, b, ldb, ii, jj, rev)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This is an auxiliary routine that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

Input Parameters

m (global) INTEGER.
m is the order of the square submatrix that is copied.

	$m \geq 0$. Unchanged on exit.
<i>i</i>	(global) INTEGER. $A(i, i)$ is the global location that the copying starts from. Unchanged on exit.
<i>a</i>	(global). REAL for pslacp3 DOUBLE PRECISION for pdlacp3 Array, DIMENSION (<i>desca</i> (<i>lld_</i>),*). On entry, the parallel matrix to be copied into or from.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix A.
<i>b</i>	(local). REAL for pslacp3 DOUBLE PRECISION for pdlacp3 Array, DIMENSION (<i>ldb</i> , <i>m</i>). If <i>rev</i> = 0, this is the global portion of the array $A(i:i+m-1, i:i+m-1)$. If <i>rev</i> = 1, this is the unchanged on exit.
<i>ldb</i>	(local) INTEGER. The leading dimension of <i>B</i> .
<i>ii</i>	(global) INTEGER. By using <i>rev</i> 0 and 1, data can be sent out and returned again. If <i>rev</i> = 0, then <i>ii</i> is destination row index for the node(s) receiving the replicated <i>B</i> . If <i>ii</i> ≥ 0 , <i>jj</i> ≥ 0 , then node (<i>ii</i> , <i>jj</i>) receives the data. If <i>ii</i> = -1, <i>jj</i> ≥ 0 , then all rows in column <i>jj</i> receive the data. If <i>ii</i> ≥ 0 , <i>jj</i> = -1, then all cols in row <i>ii</i> receive the data. If <i>ii</i> = -1, <i>jj</i> = -1, then all nodes receive the data. If <i>rev</i> != 0, then <i>ii</i> is the source row index for the node(s) sending the replicated <i>B</i> .
<i>jj</i>	(global) INTEGER. Similar description as <i>ii</i> above.
<i>rev</i>	(global) INTEGER. Use <i>rev</i> = 0 to send global <i>A</i> into locally replicated <i>B</i> (on node (<i>ii</i> , <i>jj</i>)). Use <i>rev</i> != 0 to send locally replicated <i>B</i> from node (<i>ii</i> , <i>jj</i>) to its owner (which changes depending on its location in <i>A</i>) into the global <i>A</i> .

Output Parameters

a	(global). On exit, if $rev = 1$, the copied data. Unchanged on exit if $rev = 0$.
b	(local). If $rev = 1$, this is unchanged on exit.

p?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call pslacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine copies all or part of a distributed matrix A to another distributed matrix B . No communication is performed, `p?lacpy` performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

Input Parameters

$uplo$	(global). CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not referenced. Otherwise: all of the matrix $\text{sub}(A)$ is copied.
m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) INTEGER.

	<p>The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(A). ($n \geq 0$).</p>
<i>a</i>	<p>(local). REAL for pslacpy DOUBLE PRECISION for pdlacpy COMPLEX for pclacpy COMPLEX*16 for pzlacpy. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the distributed matrix sub(A).</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix sub(A), respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix A.</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of sub(B) respectively.</p>
<i>descb</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix A.</p>

Output Parameters

<i>b</i>	<p>(local). REAL for pslacpy DOUBLE PRECISION for pdlacpy COMPLEX for pclacpy COMPLEX*16 for pzlacpy. Pointer into the local memory to an array of DIMENSION (<i>lld_b</i>, <i>LOCc(jb+n-1)</i>). This array contains on exit the local pieces of the distributed matrix sub(B) set as follows: if <i>uplo</i> = 'U', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq j, 1 \leq j \leq n$; if <i>uplo</i> = 'L', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $j \leq i \leq m, 1 \leq j \leq n$;</p>
----------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq m$,
 $1 \leq j \leq n$.

p?laevswp

Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.

Syntax

```
call pslaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pdlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pclaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pzlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

n (global). INTEGER.

The order of the matrix A . $n \geq 0$.

zin (local).

REAL for pslaevswp

DOUBLE PRECISION for pdlaevswp

COMPLEX for pclaevswp

COMPLEX*16 for pzlaevswp. Array, DIMENSION ($ldzi$, $nvs(iam)$). The eigenvectors on input. Each eigenvector resides entirely in one process. Each process holds a

	contiguous set of $nvs(iam)$ eigenvectors. The first eigenvector which the process holds is: sum for $i=[0, iam-1]$ of $nvs(i)$.
<i>ldzi</i>	(local) INTEGER. The leading dimension of the <i>zin</i> array.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i> .
<i>nvs</i>	(global) INTEGER. Array, DIMENSION (<i>nprocs</i> +1) $nvs(i)$ = number of processes number of eigenvectors held by processes $[0, i-1]$ $nvs(1)$ = number of eigen vectors held by $[0, 1 -1] = 0$ $nvs(nprocs+1)$ = number of eigen vectors held by $[0, nprocs)$ = total number of eigenvectors.
<i>key</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). Indicates the actual index (after sorting) for each of the eigenvectors.
<i>rwork</i>	(local). REAL for pslaevswp DOUBLE PRECISION for pdlaevswp COMPLEX for pclaevswp COMPLEX*16 for pzlaevswp. Array, DIMENSION (<i>lrwork</i>).
<i>lrwork</i>	(local) INTEGER. Dimension of <i>work</i> .

Output Parameters

<i>z</i>	(local). REAL for pslaevswp DOUBLE PRECISION for pdlaevswp COMPLEX for pclaevswp COMPLEX*16 for pzlaevswp.
----------	------------------------------------------------------------------------------------------------------------------------

Array, global DIMENSION (n, n), local DIMENSION ($descz(dlen_), nq$). The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of nb .

p?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .

Syntax

```
call pslahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pdlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pclahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pzlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine reduces the first nb columns of a real general n -by- $(n-k+1)$ distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$ so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q'^*A*Q . The routine returns the matrices V and T which determine Q as a block reflector $I-V*T*V'$, and also the matrix $Y = A*V*T$.

This is an auxiliary routine called by `p?gehrd`. In the following comments $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

n (global) INTEGER.
The order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.

k (global) INTEGER.

	The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
<i>nb</i>	(global) INTEGER. The number of columns to be reduced.
<i>a</i>	(local). REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i> , <i>LOCc(ja+n-k)</i>). On entry, this array contains the local pieces of the n -by- $(n-k+1)$ general distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the global array <i>Y</i> indicating the first row and the first column of the submatrix sub(<i>Y</i>), respectively.
<i>descy</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Y</i> .
<i>work</i>	(local). REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Array, DIMENSION (<i>nb</i>).

Output Parameters

<i>a</i>	(local). On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the k -th subdiagonal, with the
----------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	array <i>tau</i> , represent the matrix <i>Q</i> as a product of elementary reflectors. The other columns of $A(ia:ia+n-1, ja:ja+n-k)$ are unchanged. (See <i>Application Notes</i> below.)
<i>tau</i>	(local) REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Array, DIMENSION $LOCc(ja+n-2)$. The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>t</i>	(local)REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Array, DIMENSION (nb_a, nb_a) The upper triangular matrix <i>T</i> .
<i>y</i>	(local). REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Pointer into the local memory to an array of DIMENSION (lld_y, nb_a) . On exit, this array contains the local pieces of the <i>n</i> -by- <i>nb</i> distributed matrix <i>Y</i> . $lld_y \geq LOCr(ia+n-1)$.

Application Notes

The matrix *Q* is represented as a product of *nb* elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $A(ia+i+k:ia+n-1, ja+i-1)$, and *tau* in $TAU(ja+i-1)$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form: $A(ia:ia+n-1, ja:ja+n-k) := (I-V*T*V')*(A(ia:ia+n-1, ja:ja+n-k)-Y*V')$. The contents of $A(ia:ia+n-1, ja:ja+n-k)$ on exit are illustrated by the following example with $n = 7$, $k = 3$, and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix $A(ia:ia+n-1, ja:ja+n-k)$, h denotes a modified element of the upper Hessenberg matrix H , and vi denotes an element of the vector defining $H(i)$.

p?laiect

Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).

Syntax

```
void pslaiect(float *sigma, int *n, float *d, int *count);
void pdlaiectb(float *sigma, int *n, float *d, int *count);
void pdlaiectl(float *sigma, int *n, float *d, int *count);
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the number of negative eigenvalues of $(A - \sigma I)$. This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real routine `pslaiect` is assumed to be bit 32. Double precision routines `pdlaiectb` and `pdlaiectl` differ in the order of the double precision word storage and,

consequently, in the signbit location. For `pdlaiectb`, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For `pdlaiectl`, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

sigma Real for `pslaiect`
 DOUBLE PRECISION for `pdlaiectb/pdlaiectl`.
 The shift. `p?laiect` finds the number of eigenvalues less than equal to *sigma*.

n INTEGER. The order of the tridiagonal matrix *T*. $n \geq 1$.

d Real for `pslaiect`
 DOUBLE PRECISION for `pdlaiectb/pdlaiectl`.
 Array of DIMENSION $(2n - 1)$.
 On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix *T*. These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of *T* are in the entries $d(1), d(3), \dots, d(2n-1)$, while the squares of the off-diagonal entries are $d(2), d(4), \dots, d(2n-2)$. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

Output Parameters

n INTEGER. The count of the number of eigenvalues of *T* less than or equal to *sigma*.

p?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

Syntax

```
val = pslange(norm, m, n, a, ia, ja, desca, work)
val = pdlange(norm, m, n, a, ia, ja, desca, work)
val = pclange(norm, m, n, a, ia, ja, desca, work)
val = pzlange(norm, m, n, a, ia, ja, desca, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	(global) CHARACTER. Specifies what value is returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A , it s not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>m</i>	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, <code>p?lange</code> is set to zero. $m \geq 0$.
<i>n</i>	(global). INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(A).
When $n = 0$, p?lange is set to zero. $n \geq 0$.

a (local).
Real for pslange
DOUBLE PRECISION for pdlange
COMPLEX for pclange
COMPLEX*16 for pzlange.
Pointer into the local memory to an array of DIMENSION (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the distributed matrix sub(A).

ia, *ja* (global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix sub(A), respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix A.

work (local).
Real for pslange
DOUBLE PRECISION for pdlange
COMPLEX for pclange
COMPLEX*16 for pzlange.
Array DIMENSION (*lwork*).
lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),
*nq*0 if *norm* = '1', 'O' or 'o',
*mp*0 if *norm* = 'I' or 'i',
0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
where
iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),
iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),
iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),
*mp*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),
*nq*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),

`indxg2p` and `numroc` are ScaLAPACK tool routines; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

`val` The value returned by the routine.

p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Syntax

```
val = pslanhs(norm, n, a, ia, ja, desca, work)
val = pdlanhs(norm, n, a, ia, ja, desca, work)
val = pclanhs(norm, n, a, ia, ja, desca, work)
val = pzlanhs(norm, n, a, ia, ja, desca, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

`norm` CHARACTER*1. Specifies the value to be returned by the routine:

- = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
- = '1' or 'O' or 'o': $val = \text{norml}(A)$, 1-norm of the matrix A (maximum column sum),
- = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),

= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

n (global) INTEGER.
The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$.
When $n = 0$, $p?lanhs$ is set to zero. $n \geq 0$.

a (local).
Real for $p\text{slanhs}$
DOUBLE PRECISION for $p\text{dlanhs}$
COMPLEX for $p\text{clanhs}$
COMPLEX*16 for $p\text{zlanhs}$.
Pointer into the local memory to an array of
DIMENSION(lld_a , $LOCc(ja+n-1)$) containing the local pieces of the distributed matrix $\text{sub}(A)$.

ia, ja (global) INTEGER.
The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .

work (local).
Real for $p\text{slanhs}$
DOUBLE PRECISION for $p\text{dlanhs}$
COMPLEX for $p\text{clanhs}$
COMPLEX*16 for $p\text{zlanh}$.
Array, DIMENSION ($lwork$).
 $lwork \geq 0$ if $norm = 'M'$ or $'m'$ (not referenced),
 $nq0$ if $norm = '1'$, $'O'$ or $'o'$,
 $mp0$ if $norm = 'I'$ or $'i'$,
 0 if $norm = 'F'$, $'f'$, $'E'$ or $'e'$ (not referenced),
where
 $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$,
 $mp0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcot)$,

`indxg2p` and `numroc` are ScaLAPACK tool routines; `myrow`, `imycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

`val` The value returned by the fuction.

p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

Syntax

```
val = pslansy(norm, uplo, n, a, ia, ja, desca, work)
val = pdlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclansy(norm, uplo, n, a, ia, ja, desca, work)
val = pzlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclanhe(norm, uplo, n, a, ia, ja, desca, work)
val = pzlanhe(norm, uplo, n, a, ia, ja, desca, work)
```

Description

The routines return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

`norm` (global) CHARACTER. Specifies what value is returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A , it s not a matrix norm.
 = '1' or 'O' or 'o': $val = \text{norml}(A)$, 1-norm of the matrix A (maximum column sum),

= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
uplo (global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced.
 = 'U': Upper triangular part of $\text{sub}(A)$ is referenced,
 = 'L': Lower triangular part of $\text{sub}(A)$ is referenced.
n (global) INTEGER.
 The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, *p?lansy* is set to zero. $n \geq 0$.
a (local).
 Real for *pslansy*
 DOUBLE PRECISION for *pdlansy*
 COMPLEX for *pclansy*, *pclanhe*
 COMPLEX*16 for *pzlansy*, *pzlanhe*.
 Pointer into the local memory to an array of DIMENSION (*lld_a*, *LOCc(ja+n-1)*) containing the local pieces of the distributed matrix $\text{sub}(A)$.
 If *uplo* = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If *uplo* = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
ia, ja (global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
desca (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix A .
work (local).
 Real for *pslansy*
 DOUBLE PRECISION for *pdlansy*
 COMPLEX for *pclansy*, *pclanhe*

```

COMPLEX*16 for pzlansy, pzlanhe.
Array DIMENSION (lwork).
lwork ≥ 0 if norm = 'M' or 'm' (not referenced),
2*nq0+np0+ldw if norm = '1', 'O' or 'o', 'I' or 'i',
where ldw is given by:
if( nprow.ne.npcol ) then
ldw = mb_a*ceil(ceil(np0/mb_a)/(lcm/nprow))
else
ldw = 0
end if
0 if norm = 'F', 'f', 'E' or 'e' (not referenced),
where lcm is the least common multiple of nprow and
npcol, lcm = ilcm( nprow, npcil ) and ceil denotes
the ceiling operation (iceil).
iroffa = mod(ia-1, mb_a ), icoffa = mod( ja-1, nb_a ),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcil),
mp0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
nq0 = numroc(n+icoffa, nb_a, mycol, iacol, npcil),
indxg2p and numroc are ScaLAPACK tool functions; myrow,
mycol, nprow, and npcil can be determined by calling the
subroutine blacs_gridinfo.

```

Output Parameters

val

The value returned by the routine.

p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

```
val = pslantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pdlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pclantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pzlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix `sub(A)` = `A(ia:ia+m-1, ja:ja+n-1)`.

Input Parameters

<i>norm</i>	<p>(global) CHARACTER. Specifies what value is returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': <code>val = max(abs(A_{ij}))</code>, largest absolute value of the matrix <code>A</code>, it s not a matrix norm. = '1' or 'O' or 'o': <code>val = norm1(A)</code>, 1-norm of the matrix <code>A</code> (maximum column sum), = 'I' or 'i': <code>val = normI(A)</code>, infinity norm of the matrix <code>A</code> (maximum row sum), = 'F', 'f', 'E' or 'e': <code>val = normF(A)</code>, Frobenius norm of the matrix <code>A</code> (square root of sum of squares).
<i>uplo</i>	<p>(global) CHARACTER.</p> <p>Specifies whether the upper or lower triangular part of the symmetric matrix <code>sub(A)</code> is to be referenced.</p> <ul style="list-style-type: none"> = 'U': Upper trapezoidal, = 'L': Lower trapezoidal. <p>Note that <code>sub(A)</code> is triangular instead of trapezoidal if <code>m = n</code>.</p>

<i>diag</i>	<p>(global). CHARACTER. Specifies whether the distributed matrix sub(<i>A</i>) has unit diagonal. = 'N': Non-unit diagonal. = 'U': Unit diagonal.</p>
<i>m</i>	<p>(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>A</i>). When $m = 0$, <i>p?lantr</i> is set to zero. $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER. The number of columns to be operated on i.e the number of columns of the distributed submatrix sub(<i>A</i>). When $n = 0$, <i>p?lantr</i> is set to zero. $n \geq 0$.</p>
<i>a</i>	<p>(local). Real for <i>p?lantr</i> DOUBLE PRECISION for <i>pdlantr</i> COMPLEX for <i>pclantr</i> COMPLEX*16 for <i>pzlantr</i>. Pointer into the local memory to an array of DIMENSION(<i>lld_a</i>, <i>LOCc(ja+n-1)</i>) containing the local pieces of the distributed matrix sub(<i>A</i>).</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p>
<i>work</i>	<p>(local). Real for <i>p?lantr</i> DOUBLE PRECISION for <i>pdlantr</i> COMPLEX for <i>pclantr</i> COMPLEX*16 for <i>pzlantr</i>. Array DIMENSION (<i>lwork</i>). <i>lwork</i> ≥ 0 if <i>norm</i> = 'M' or 'm' (not referenced), <i>nq</i>0 if <i>norm</i> = '1', 'O' or 'o', <i>mp</i>0 if <i>norm</i> = 'I' or 'i',</p>

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
 where *lcm* is the least common multiple of *nprow* and *npcol*
 $lcm = \text{ilcm}(nprow, npcol)$ and *ceil* denotes the ceiling
 operation (*iceil*).
 $iroffa = \text{mod}(ia-1, mb_a), icoffa = \text{mod}(ja-1,$
 $nb_a),$
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow),$
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol),$
 $mp0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow,$
 $nprow),$
 $nq0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol,$
 $npcol),$
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*,
mycol, *nprow*, and *npcol* can be determined by calling the
 subroutine *blacs_gridinfo*.

Output Parameters

val The value returned by the routine.

p?lapiv

*Applies a permutation matrix to a general
 distributed matrix, resulting in row or column
 pivoting.*

Syntax

```
call pslapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)

call pdlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)

call pclapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)

call pzlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine applies either P (permutation matrix indicated by *ipiv*) or $\text{inv}(P)$ to a general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$, resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix A . This routine will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of $\text{sub}(A)$, pass *rowcol*='C' and *pivroc*='C'.

Input Parameters

<i>direc</i>	<p>(global) CHARACTER*1. Specifies in which order the permutation is applied: = 'F' (Forward). Applies pivots forward from top of matrix. Computes $P * \text{sub}(A)$. = 'B' (Backward). Applies pivots backward from bottom of matrix. Computes $\text{inv}(P) * \text{sub}(A)$.</p>
<i>rowcol</i>	<p>(global) CHARACTER*1. Specifies if the rows or columns are to be permuted: = 'R' Rows will be permuted, = 'C' Columns will be permuted.</p>
<i>pivroc</i>	<p>(global) CHARACTER*1. Specifies whether <i>ipiv</i> is distributed over a process row or column: = 'R' <i>ipiv</i> is distributed over a process row, = 'C' <i>ipiv</i> is distributed over a process column.</p>
<i>m</i>	<p>(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, <i>p?lapiv</i> is set to zero. $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, <i>p?lapiv</i> is set to zero. $n \geq 0$.</p>
<i>a</i>	<p>(local). Real for <i>pslapiv</i></p>

DOUBLE PRECISION for pdlapiv
 COMPLEX for pclapiv
 COMPLEX*16 for pzlapiv.
 Pointer into the local memory to an array of
 DIMENSION(lld_a , $LOCc(ja+n-1)$) containing the local
 pieces of the distributed matrix sub(A).

ia, ja (global) INTEGER.
 The row and column indices in the global array A indicating
 the first row and the first column of the submatrix sub(A),
 respectively.

desca (global and local) INTEGER array, DIMENSION ($dlen_$). The
 array descriptor for the distributed matrix A .

ipiv (local). INTEGER.
 Array, DIMENSION ($lipiv$) ;
 when $rowcol='R'$ or $'r'$:
 $lipiv \geq LOCr(ia+m-1) + mb_a$ if $pivroc='C'$ or $'c'$,
 $lipiv \geq LOCc(m + mod(jp-1, nb_p))$ if $pivroc='R'$ or
 $'r'$, and,
 when $rowcol='C'$ or $'c'$:
 $lipiv \geq LOCr(n + mod(ip-1, mb_p))$ if $pivroc='C'$ or
 $'c'$,
 $lipiv \geq LOCc(ja+n-1) + nb_a$ if $pivroc='R'$ or $'r'$.
 This array contains the pivoting information. $ipiv(i)$ is the
 global row (column), local row (column) i was swapped
 with. When $rowcol='R'$ or $'r'$ and $pivroc='C'$ or $'c'$,
 or $rowcol='C'$ or $'c'$ and $pivroc='R'$ or $'r'$, the last
 piece of this array of size mb_a (resp. nb_a) is used as
 workspace. In those cases, this array is tied to the
 distributed matrix A .

ip, jp (global) INTEGER. The row and column indices in the global
 array P indicating the first row and the first column of the
 submatrix sub(P), respectively.

descip (global and local) INTEGER array, DIMENSION ($dlen_$). The
 array descriptor for the distributed vector $ipiv$.

iwork (local). INTEGER.

Array, DIMENSION (*ldw*), where *ldw* is equal to the workspace necessary for transposition, and the storage of the transposed *ipiv* :

Let *lcm* be the least common multiple of *nprow* and *npcol*.

If(*rowcol*.eq.'r' .and. *pivroc*. eq.'r') then

If(*nprow*.eq. *npcol*) then

ldw = LOCr(*n_p* + mod(*jp*-1, *nb_p*)) + *nb_p*

else

ldw = LOCr(*n_p* + mod(*jp*-1, *nb_p*)) +

nb_p * ceil(ceil(LOCc(*n_p*)/*nb_p*) / (*lcm*/*npcol*))

end if

else if(*rowcol*.eq.'c' .and. *pivroc*.eq.'c') then

if(*nprow*.eq.

npcol) then

ldw = LOCc(*m_p* + mod(*ip*-1, *mb_p*)) + *mb_p*

else

ldw = LOCc(*m_p* + mod(*ip*-1, *mb_p*)) +

mb_p *ceil(ceil(LOCr(*m_p*)/*mb_p*) / (*lcm*/*nprow*))

end if

else

iwork is not referenced.

end if.

Output Parameters

a

(local).

On exit, the local pieces of the permuted distributed submatrix.

p?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ .

Syntax

```
call pslaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pdlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pclaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pzlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine equilibrates a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using the row and scaling factors in the vectors r and c computed by `p?geequ`.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). REAL for pslaqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge. Pointer into the local memory to an array of DIMENSION(lld_a , $LOCc(ja+n-1)$). On entry, this array contains the distributed matrix $\text{sub}(A)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>r</i>	(local). REAL for pslagge DOUBLE PRECISION for pdlagge COMPLEX for pclagge COMPLEX*16 for pzlagge. Array, DIMENSION <i>LOCr(m_a)</i> . The row scale factors for <i>sub(A)</i> . <i>r</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>r</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local). REAL for pslagge DOUBLE PRECISION for pdlagge COMPLEX for pclagge COMPLEX*16 for pzlagge. Array, DIMENSION <i>LOCc(n_a)</i> . The row scale factors for <i>sub(A)</i> . <i>c</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>c</i> is tied to the distributed matrix <i>A</i> .
<i>rowcnd</i>	(local). REAL for pslagge DOUBLE PRECISION for pdlagge COMPLEX for pclagge COMPLEX*16 for pzlagge. The global ratio of the smallest <i>r(i)</i> to the largest <i>r(i)</i> , $ia \leq i \leq ia+m-1$.
<i>colcnd</i>	(local). REAL for pslagge DOUBLE PRECISION for pdlagge COMPLEX for pclagge COMPLEX*16 for pzlagge.

The global ratio of the smallest $c(i)$ to the largest $c(i)$,
 $ia \leq i \leq ia+n-1$.

amax (global). REAL for pslaqge
 DOUBLE PRECISION for pdlaqge
 COMPLEX for pclaqge
 COMPLEX*16 for pzlaqge.
 Absolute value of largest distributed submatrix entry.

Output Parameters

a (local).
 On exit, the equilibrated distributed matrix. See *equed* for the form of the equilibrated distributed submatrix.

equed (global) CHARACTER.
 Specifies the form of equilibration that was done.
 = 'N': No equilibration
 = 'R': Row equilibration, that is, $\text{sub}(A)$ has been pre-multiplied by $\text{diag}(r(ia:ia+m-1))$,
 = 'C': column equilibration, that is, $\text{sub}(A)$ has been post-multiplied by $\text{diag}(c(ja:ja+n-1))$,
 = 'B': Both row and column equilibration, that is, $\text{sub}(A)$ has been replaced by $\text{diag}(r(ia:ia+m-1)) * \text{sub}(A) * \text{diag}(c(ja:ja+n-1))$.

p?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.

Syntax

```
call pslaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pdlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pclaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pzlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine equilibrates a symmetric distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the scaling factors in the vectors *sr* and *sc*. The scaling factors are computed by [p?poequ](#).

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>a</i>	(local). REAL for pslagsy DOUBLE PRECISION for pdlagsy COMPLEX for pclagsy COMPLEX*16 for pzlagsy. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. On entry, the local pieces of the distributed symmetric matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

<i>sr</i>	<p>(local)</p> <p>REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy.</p> <p>Array, DIMENSION $LOCr(m_a)$. The scale factors for $A(ia:ia+m-1, ja:ja+n-1)$. <i>sr</i> is aligned with the distributed matrix <i>A</i>, and replicated across every process column. <i>sr</i> is tied to the distributed matrix <i>A</i>.</p>
<i>sc</i>	<p>(local)</p> <p>REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy.</p> <p>Array, DIMENSION $LOCc(m_a)$. The scale factors for $A(ia:ia+m-1, ja:ja+n-1)$. <i>sc</i> is aligned with the distributed matrix <i>A</i>, and replicated across every process column. <i>sc</i> is tied to the distributed matrix <i>A</i>.</p>
<i>scond</i>	<p>(global). REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy.</p> <p>Ratio of the smallest $sr(i)$ (respectively $sc(j)$) to the largest $sr(i)$ (respectively $sc(j)$), with $ia \leq i \leq ia+n-1$ and $ja \leq j \leq ja+n-1$.</p>
<i>amax</i>	<p>(global).</p> <p>REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy.</p> <p>Absolute value of largest distributed submatrix entry.</p>

Output Parameters

<i>a</i>	<p>On exit, if <i>equed</i> = 'Y', the equilibrated matrix:</p>
----------	----------------------------------------------------------------------

```

                                diag(sr(ia:ia+n-1)) * sub(A) *
                                diag(sc(ja:ja+n-1)).
eques                           (global) CHARACTER*1.
                                Specifies whether or not equilibration was done.
                                = 'N': No equilibration.
                                = 'Y': Equilibration was done, that is, sub(A) has been
                                replaced by:
                                diag(sr(ia:ia+n-1)) * sub(A) *
                                diag(sc(ja:ja+n-1)).

```

p?lared1d

Redistributes an array assuming that the input array, `bycol`, is distributed across rows and that all process columns contain the same copy of `bycol`.

Syntax

```

call pslared1d(n, ia, ja, desc, bycol, byall, work, lwork)
call pdlared1d(n, ia, ja, desc, bycol, byall, work, lwork)

```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine redistributes a 1D array. It assumes that the input array `bycol` is distributed across rows and that all process column contain the same copy of `bycol`. The output array `byall` is identical on all processes and contains the entire array.

Input Parameters

<code>np</code>	= Number of local rows in <code>bycol()</code>
<code>n</code>	(global). INTEGER. The number of elements to be redistributed. $n \geq 0$.
<code>ia, ja</code>	(global) INTEGER. <code>ia, ja</code> must be equal to 1.
<code>desc</code>	(global and local) INTEGER array, DIMENSION 8. A 2D array descriptor, which describes <code>bycol</code> .
<code>bycol</code>	(local).

work
 REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlarred1d.
 Distributed block cyclic array global DIMENSION (n), local
 DIMENSION np . $bycol$ is distributed across the process rows.
 All process columns are assumed to contain the same value.
 (local).
 REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlarred1d.
 DIMENSION ($lwork$). Used to hold the buffers sent from one
 process to another.
lwork
 (local)
 INTEGER. The size of the *work* array. $lwork \geq \text{numroc}(n,$
 $\text{desc}(nb_), 0, 0, npcol)$.

Output Parameters

byall
 (global). REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlarred1d.
 Global DIMENSION (n), local DIMENSION (n). *byall* is exactly
 duplicated on all processes. It contains the same values as
bycol, but it is replicated across all processes rather than
 being distributed.

p?lared2d

Redistributes an array assuming that the input array `byrow` is distributed across columns and that all process rows contain the same copy of `byrow`.

Syntax

```
call pslared2d(n, ia, ja, desc, byrow, byall, work, lwork)
call pdlared2d(n, ia, ja, desc, byrow, byall, work, lwork)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine redistributes a 1D array. It assumes that the input array `byrow` is distributed across columns and that all process rows contain the same copy of `byrow`. The output array `byall` will be identical on all processes and will contain the entire array.

Input Parameters

`np` = Number of local rows in `byrow()`

`n` (global) INTEGER.
The number of elements to be redistributed. $n \geq 0$.

`ia, ja` (global) INTEGER. `ia, ja` must be equal to 1.

`desc` (global and local) INTEGER array, DIMENSION (`dlen_`). A 2D array descriptor, which describes `byrow`.

`byrow` (local).
REAL for `pslared2d`
DOUBLE PRECISION for `pdlared2d`
COMPLEX for `pclared2d`
COMPLEX*16 for `pzlared2d`.
Distributed block cyclic array global DIMENSION (`n`), local DIMENSION `np`. `bycol` is distributed across the process columns. All process rows are assumed to contain the same value.

`work` (local).
REAL for `pslared2d`
DOUBLE PRECISION for `pdlared2d`

COMPLEX for pclared2d
 COMPLEX*16 for pzlarred2d.
 DIMENSION (*lwork*). Used to hold the buffers sent from one process to another.

lwork (local). INTEGER. The size of the *work* array. $lwork \geq \text{numroc}(n, \text{desc}(nb_), 0, 0, npcol)$.

Output Parameters

byall (global). REAL for pslared2d
 DOUBLE PRECISION for pdlared2d
 COMPLEX for pclared2d
 COMPLEX*16 for pzlarred2d.
 Global DIMENSION(*n*), local DIMENSION (*n*). *byall* is exactly duplicated on all processes. It contains the same values as *bycol*, but it is replicated across all processes rather than being distributed.

p?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

```
call pslarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau * v * v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global) CHARACTER. = 'L': form $Q \cdot \text{sub}(C)$, = 'R': form $\text{sub}(C) \cdot Q$, $Q = Q^T$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>v</i>	(local). REAL for <code>pslarf</code> DOUBLE PRECISION for <code>pdlarf</code> COMPLEX for <code>pclarf</code> COMPLEX*16 for <code>pzlarf</code> . Pointer into the local memory to an array of DIMENSION (<i>lld_v</i> ,*) containing the local pieces of the distributed vectors <i>v</i> representing the Householder transformation Q , $v(iv:iv+m-1, jv)$ if <i>side</i> = 'L' and <i>incv</i> = 1, $v(iv, jv:jv+m-1)$ if <i>side</i> = 'L' and <i>incv</i> = m_v , $v(iv:iv+n-1, jv)$ if <i>side</i> = 'R' and <i>incv</i> = 1, $v(iv, jv:jv+n-1)$ if <i>side</i> = 'R' and <i>incv</i> = m_v . The vector <i>v</i> is the representation of Q . <i>v</i> is not used if $\tau = 0$.
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>V</i> .
<i>incv</i>	(global) INTEGER. The global increment for the elements of <i>v</i> . Only two values of <i>incv</i> are supported in this version, namely 1 and m_v . <i>incv</i> must not be zero.

<i>tau</i>	<p>(local).</p> <p>REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf.</p> <p>Array, DIMENSION $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>v</i>.</p>
<i>c</i>	<p>(local).</p> <p>REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf.</p> <p>Pointer into the local memory to an array of DIMENSION($lld_c, LOCc(jc+n-1)$), containing the local pieces of sub(<i>c</i>).</p>
<i>ic, jc</i>	<p>(global) INTEGER.</p> <p>The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix sub(<i>c</i>), respectively.</p>
<i>desc</i>	<p>(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix <i>c</i>.</p>
<i>work</i>	<p>(local).</p> <p>REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf.</p> <p>Array, DIMENSION ($lwork$).</p> <p>If $incv = 1$, if $side = 'L'$, if $ivcol = iccol$, $lwork \geq nqc0$ else $lwork \geq mpc0 + \max(1, nqc0)$ end if else if $side = 'R'$,</p>

```

        lwork ≥ nqc0 + max( max( 1, mpc0 ), numroc( numroc( n+
            icoffc, nb_v, 0, 0, npcol ), nb_v, 0, 0, lcmq ) )
    end if
else if incv = m_v,
    if side = 'L',
        lwork ≥ mpc0 + max( max( 1, nqc0 ), numroc(
            numroc( m+iroffc, mb_v, 0, 0, nprow ), mb_v, 0, 0, lcmq )
        )
    else if side = 'R',
        if ivrow = icrow,
            lwork ≥ mpc0
        else
            lwork ≥ nqc0 + max( 1, mpc0 )
        end if
    end if
end if,
where lcm is the least common multiple of nprow and npcol
and lcm = ilcm( nprow, npcol ), lcmq = lcm/nprow, lcmq
= lcm/npcol,
iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1,
nb_c ),
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nprow
),
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol
),
mpc0 = numroc( m+iroffc, mb_c, myrow, icrow,
nprow ),
nqc0 = numroc( n+icoffc, nb_c, mycol, iccol,
npcol ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npcol can be determined by
calling the subroutine blacs_gridinfo.

```

Output Parameters

c

(local).

On exit, sub(*c*) is overwritten by the $Q \cdot \text{sub}(C)$ if *side* = 'L',

or $\text{sub}(c) * Q$ if $\text{side} = 'R'$.

p?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```
call pslarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c,
ic, jc, descc, work)
```

```
call pdlarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c,
ic, jc, descc, work)
```

```
call pclarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c,
ic, jc, descc, work)
```

```
call pzlarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c,
ic, jc, descc, work)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine applies a real/complex block reflector Q or its transpose Q^T /conjugate transpose Q^H to a real/complex distributed m -by- n matrix $\text{sub}(c) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Input Parameters

<i>side</i>	(global).CHARACTER. if <i>side</i> = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Left; if <i>side</i> = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Right.
<i>trans</i>	(global).CHARACTER. if <i>trans</i> = 'N': no transpose, apply Q ; for real flavors, if <i>trans</i> ='T': transpose, apply Q^T for complex flavors, if <i>trans</i> = 'C': conjugate transpose, apply Q^H ;

<i>direct</i>	<p>(global) CHARACTER. Indicates how Q is formed from a product of elementary reflectors.</p> <p>if <i>direct</i> = 'F': $Q = H(1)*H(2)*\dots*H(k)$ (Forward)</p> <p>if <i>direct</i> = 'B': $Q = H(k)*\dots*H(2)*H(1)$ (Backward)</p>
<i>storev</i>	<p>(global) CHARACTER.</p> <p>Indicates how the vectors that define the elementary reflectors are stored:</p> <p>if <i>storev</i> = 'C': Columnwise</p> <p>if <i>storev</i> = 'R': Rowwise.</p>
<i>m</i>	<p>(global) INTEGER.</p> <p>The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>c</i>). ($m \geq 0$).</p>
<i>n</i>	<p>(global) INTEGER.</p> <p>The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(<i>c</i>). ($n \geq 0$).</p>

ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npcol can be determined by
calling the subroutine blacs_gridinfo.

```

Output Parameters

<i>t</i>	<p>(local). REAL for pslarfb DOUBLE PRECISION for pdlarfb COMPLEX for pclarfb COMPLEX*16 for pzlarfb. Array, DIMENSION(<i>mb_v</i>, <i>mb_v</i>) if <i>storev</i> = 'R', and (<i>nb_v</i>, <i>nb_v</i>) if <i>storev</i> = 'C'. The triangular matrix <i>t</i> is the representation of the block reflector.</p>
<i>c</i>	<p>(local). On exit, sub(<i>c</i>) is overwritten by the $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q'$. Q' is transpose (conjugate transpose) of Q.</p>

p?larfc

Applies the conjugate transpose of an elementary reflector to a general matrix.

Syntax

```
call pclarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v^H,$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global). CHARACTER. if <i>side</i> = 'L': form $Q^H * \text{sub}(C)$; if <i>side</i> = 'R': form $\text{sub}(C) * Q^H$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<i>v</i>	(local). COMPLEX for pclarfc COMPLEX*16 for pzlarfc.

	<p>Pointer into the local memory to an array of <code>DIMENSION (lld_v,*)</code> containing the local pieces of the distributed vectors <code>v</code> representing the Householder transformation <code>Q</code>, <code>v(iv:iv+m-1, jv)</code> if <code>side = 'L'</code> and <code>incv = 1</code>, <code>v(iv, jv:jv+m-1)</code> if <code>side = 'L'</code> and <code>incv = m_v</code>, <code>v(iv:iv+n-1, jv)</code> if <code>side = 'R'</code> and <code>incv = 1</code>, <code>v(iv, jv:jv+n-1)</code> if <code>side = 'R'</code> and <code>incv = m_v</code>. The vector <code>v</code> is the representation of <code>Q</code>. <code>v</code> is not used if <code>tau = 0</code>.</p>
<code>iv, jv</code>	<p>(global) INTEGER. The row and column indices in the global array <code>v</code> indicating the first row and the first column of the submatrix <code>sub(v)</code>, respectively.</p>
<code>descv</code>	<p>(global and local) INTEGER array, <code>DIMENSION (dlen_)</code>. The array descriptor for the distributed matrix <code>v</code>.</p>
<code>incv</code>	<p>(global) INTEGER. The global increment for the elements of <code>v</code>. Only two values of <code>incv</code> are supported in this version, namely 1 and <code>m_v</code>. <code>incv</code> must not be zero.</p>
<code>tau</code>	<p>(local) COMPLEX for <code>pclarfc</code> COMPLEX*16 for <code>pzlarfc</code>. Array, <code>DIMENSION LOcc(jv)</code> if <code>incv = 1</code>, and <code>LOCr(iv)</code> otherwise. This array contains the Householder scalars related to the Householder vectors. <code>tau</code> is tied to the distributed matrix <code>v</code>.</p>
<code>c</code>	<p>(local). COMPLEX for <code>pclarfc</code> COMPLEX*16 for <code>pzlarfc</code>. Pointer into the local memory to an array of <code>DIMENSION (lld_c, LOcc(jc+n-1))</code>, containing the local pieces of <code>sub(c)</code>.</p>

Output Parameters

`c` (local).
 On exit, `sub(c)` is overwritten by the $Q^H \cdot \text{sub}(C)$ if `side = 'L'`, or `sub(C) * Q^H` if `side = 'R'`.

p?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
call pslarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pdlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pclarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pzlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine generates a real/complex elementary reflector H of order n , such that

$$H^* \text{sub}(X) = H^* (x(iax, jax)) = (\alpha), \quad H^* H = I,$$

$$\begin{pmatrix} x \\ 0 \end{pmatrix}$$

where α is a scalar (a real scalar - for complex flavors), and `sub(X)` is an $(n-1)$ -element real/complex distributed vector $X(ix:ix+n-2, jx)$ if `incx = 1` and $X(ix, jx:jx+n-2)$ if `incx = descx(m_)`. H is represented in the form

$$H = I - \tau \begin{pmatrix} 1 \\ v' \end{pmatrix} \begin{pmatrix} 1 & v \end{pmatrix},$$

(v)

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that H is not Hermitian.

If the elements of $\text{sub}(x)$ are all zero (and $X(iax, jax)$ is real for complex flavors), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise $1 \leq \text{real}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$.

Input Parameters

n	(global) INTEGER. The global order of the elementary reflector. $n \geq 0$.
iax, jax	(global) INTEGER. The global row and column indices in x of $X(iax, jax)$.
x	(local). Real for pslarfg DOUBLE PRECISION for pdlarfg COMPLEX for pclarfg COMPLEX*16 for pzlarfg. Pointer into the local memory to an array of DIMENSION $(lld_x, *)$. This array contains the local pieces of the distributed vector $\text{sub}(x)$. Before entry, the incremented array $\text{sub}(x)$ must contain vector x .
ix, jx	(global) INTEGER. The row and column indices in the global array x indicating the first row and the first column of $\text{sub}(x)$, respectively.
$descx$	(global and local) INTEGER. Array of DIMENSION $(dlen_)$. The array descriptor for the distributed matrix x .
$incx$	(global) INTEGER. The global increment for the elements of x . Only two values of $incx$ are supported in this version, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

α	(local)
----------	---------

	REAL for pslafg
	DOUBLE PRECISION for pdlafg
	COMPLEX for pclafg
	COMPLEX*16 for pzlafg.
	On exit, <i>alpha</i> is computed in the process scope having the vector sub(<i>x</i>).
<i>x</i>	(local). On exit, it is overwritten with the vector <i>v</i> .
<i>tau</i>	(local). Real for pslarfg DOUBLE PRECISION for pdlarfg COMPLEX for pclarfg COMPLEX*16 for pzlarfg. Array, DIMENSION <i>LOCc(jx)</i> if <i>incx</i> = 1, and <i>LOCr(ix)</i> otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>X</i> .

p?larft

*Forms the triangular vector *T* of a block reflector*

$$H = I - V * T * V^H.$$

Syntax

```
call pslarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine forms the triangular factor *T* of a real/complex block reflector *H* of order *n*, which is defined as a product of *k* elementary reflectors.

If *direct* = 'F', *H* = *H*(1)**H*(2) ... **H*(*k*), and *T* is upper triangular;

If *direct* = 'B', *H* = *H*(*k*)*...**H*(2)**H*(1), and *T* is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the distributed matrix V , and

$$H = I - V * T * V'$$

If $storev = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the distributed matrix V , and

$$H = I - V' * T * V.$$

Input Parameters

<i>direct</i>	(global) CHARACTER*1. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) if <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward).
<i>storev</i>	(global) CHARACTER*1. Specifies how the vectors that define the elementary reflectors are stored (See <i>Application Notes</i> below): if <i>storev</i> = 'C': columnwise; if <i>storev</i> = 'R': rowwise.
<i>n</i>	(global) INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	(global) INTEGER. The order of the triangular factor T , is equal to the number of elementary reflectors. $1 \leq k \leq mb_v$ ($= nb_v$).
<i>v</i>	REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Pointer into the local memory to an array of local DIMENSION (LOCr(iv+n-1), LOCc(jv+k-1)) if <i>storev</i> = 'C', and (LOCr(iv+k-1), LOCc(jv+n-1)) if <i>storev</i> = 'R'. The distributed matrix V contains the Householder vectors. (See <i>Application Notes</i> below).
<i>iv, jv</i>	(global) INTEGER.

	The row and column indices in the global array v indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix v .
<i>tau</i>	(local) REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Array, DIMENSION $\text{LOCr}(iv+k-1)$ if $incv = m_v$, and $\text{LOCc}(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix v .
<i>work</i>	(local). REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Workspace array, DIMENSION $(k*(k-1)/2)$.

Output Parameters

v	REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft.
t	(local) REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Array, DIMENSION (nb_v, nb_v) if $storev = 'C'$, and (mb_v, mb_v) otherwise. It contains the k -by- k triangular factor of the block reflector associated with v . If $direct = 'F'$, t is upper triangular; if $direct = 'B'$, t is lower triangular.

Application Notes

The shape of the matrix v and the storage of the vectors that define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and *storev* = 'C' :

$$V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} 1 & & & & \\ v1 & 1 & & & \\ v1 & v2 & 1 & & \\ v1 & v2 & v3 & & \\ v1 & v2 & v3 & & \end{bmatrix}$$

direct = 'F' and *storev* = 'R'

$$V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} 1 & v1 & v1 & v1 & v1 \\ & 1 & v2 & v2 & v2 \\ & & 1 & v3 & v3 \end{bmatrix}$$

direct = 'B' and *storev* = 'C'

$$V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} v1 & v2v & v3 \\ v1 & v2 & v3 \\ 1 & v2 & v3 \\ & 1 & v3 \\ & & 1 \end{bmatrix}$$

direct = 'B' and *storev* = 'R'

$$V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} v1 & v1 & 1 & & \\ v2 & v2 & v2 & 1 & \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix}$$

p?larz

Applies an elementary reflector as returned by p?tzzrf to a general matrix.

Syntax

```
call pslarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)

call pdlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)

call pclarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)

call pzlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau * v * v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by `p?tzzrf`.

Input Parameters

<i>side</i>	(global) CHARACTER. if <i>side</i> = 'L': form $Q * \text{sub}(C)$, if <i>side</i> = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$ (for real flavors).
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER.

	<p>The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).</p>
<i>l</i>	<p>(global) INTEGER.</p> <p>The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If $\text{side} = 'L', m \geq l \geq 0$,</p> <p>if $\text{side} = 'R', n \geq l \geq 0$.</p>
<i>v</i>	<p>(local).</p> <p>REAL for pslarz DOUBLE PRECISION for pdlarz COMPLEX for pclarz COMPLEX*16 for pzlarz.</p> <p>Pointer into the local memory to an array of DIMENSION ($lld_v, *$) containing the local pieces of the distributed vectors v representing the Householder transformation Q, $v(iv:iv+l-1, jv)$ if $\text{side} = 'L'$ and $incv = 1$, $v(iv, jv:jv+l-1)$ if $\text{side} = 'L'$ and $incv = m_v$, $v(iv:iv+l-1, jv)$ if $\text{side} = 'R'$ and $incv = 1$, $v(iv, jv:jv+l-1)$ if $\text{side} = 'R'$ and $incv = m_v$.</p> <p>The vector v in the representation of Q. v is not used if $\tau = 0$.</p>
<i>iv, jv</i>	<p>(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.</p>
<i>descv</i>	<p>(global and local) INTEGER array, DIMENSION ($dlen_v$). The array descriptor for the distributed matrix v.</p>
<i>incv</i>	<p>(global) INTEGER.</p> <p>The global increment for the elements of v. Only two values of $incv$ are supported in this version, namely 1 and m_v. $incv$ must not be zero.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for pslarz DOUBLE PRECISION for pdlarz COMPLEX for pclarz COMPLEX*16 for pzlarz.</p>

	<p>Array, DIMENSION $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors.</p> <p>τ is tied to the distributed matrix V.</p>
c	<p>(local).</p> <p>REAL for pslarz DOUBLE PRECISION for pdlarz COMPLEX for pclarz COMPLEX*16 for pzlarz.</p> <p>Pointer into the local memory to an array of DIMENSION $(lld_c, LOCc(jc+n-1))$, containing the local pieces of $sub(c)$.</p>
ic, jc	<p>(global) INTEGER.</p> <p>The row and column indices in the global array c indicating the first row and the first column of the submatrix $sub(c)$, respectively.</p>
$descc$	<p>(global and local) INTEGER array, DIMENSION $(dlen_)$. The array descriptor for the distributed matrix c.</p>
$work$	<p>(local).</p> <p>REAL for pslarz DOUBLE PRECISION for pdlarz COMPLEX for pclarz COMPLEX*16 for pzlarz.</p> <p>Array, DIMENSION $(lwork)$</p> <p>If $incv = 1$, if $side = 'L'$, if $ivcol = iccol$, $lwork \geq NqC0$ else $lwork \geq MpC0 + \max(1, NqC0)$ end if else if $side = 'R'$, $lwork \geq NqC0 + \max(\max(1, MpC0),$ $numroc(numroc(n+icoffc,nb_v,0,0,npcol),nb_v,0,0,lcmq))$ end if else if $incv = m_v$, if $side = 'L'$,</p>

```

    lwork ≥ MpC0 + max(max(1, NqC0),
numroc(numroc(m+iroffc,mb_v,0,0,nprow),mb_v,0,0,lcmp))
    else if side = 'R' ,
        if ivrow = icrow,
            lwork ≥ MpC0
        else
            lwork ≥ NqC0 + max(1, MpC0)
        end if
    end if
end if.

```

Here *lcm* is the least common multiple of *nprow* and *npcol* and

```

lcm = ilcm( nprow, npcol ), lcmp = lcm / nprow,
lcmq = lcm / npcol,
iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1, nb_c ),
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nprow ),
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol ),
mpc0 = numroc( m+iroffc, mb_c, myrow, icrow, nprow ),
nqc0 = numroc( n+icoffc, nb_c, mycol, iccol, npcol ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npcol can be determined by
calling the subroutine blacs_gridinfo.

```

Output Parameters

c

(local).

On exit, *sub(c)* is overwritten by the $Q \cdot \text{sub}(C)$ if *side* = 'L', or *sub(C) * Q* if *side* = 'R'.

p?larzb

Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzzrf to a general matrix.

Syntax

```
call pslarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c,
ic, jc, descc, work)

call pdlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c,
ic, jc, descc, work)

call pclarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c,
ic, jc, descc, work)

call pzlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c,
ic, jc, descc, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine applies a real/complex block reflector Q or its transpose Q^T (conjugate transpose Q^H for complex flavors) to a real/complex distributed m -by- n matrix `sub(C) = C(ic:ic+m-1, jc:jc+n-1)` from the left or the right.

Q is a product of k elementary reflectors as returned by `p?tzzrf`.

Currently, only `storev = 'R'` and `direct = 'B'` are supported.

Input Parameters

<code>side</code>	(global) CHARACTER. if <code>side = 'L'</code> : apply Q or Q^T (Q^H for complex flavors) from the Left; if <code>side = 'R'</code> : apply Q or Q^T (Q^H for complex flavors) from the Right.
<code>trans</code>	(global) CHARACTER. if <code>trans = 'N'</code> : No transpose, apply Q ; If <code>trans='T'</code> : Transpose, apply Q^T (real flavors); If <code>trans='C'</code> : Conjugate transpose, apply Q^H (complex flavors).

direct (global) CHARACTER.
Indicates how H is formed from a product of elementary reflectors.
if *direct* = 'F': $H = H(1) * H(2) * \dots * H(k)$ - forward (not supported) ;
if *direct* = 'B': $H = H(k) * \dots * H(2) * H(1)$ - backward.

storev (global) CHARACTER.
Indicates how the vectors that define the elementary reflectors are stored:
if *storev* = 'C': columnwise (not supported).
if *storev* = 'R': rowwise.

m (global) INTEGER.
The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(*c*). ($m \geq 0$).

n (global) INTEGER.
The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(*c*). ($n \geq 0$).

k (global) INTEGER.
The order of the matrix T . (= the number of elementary reflectors whose product defines the block reflector).

l (global) INTEGER.
The columns of the distributed submatrix sub(*a*) containing the meaningful part of the Householder reflectors.
If *side* = 'L', $m \geq l \geq 0$,
if *side* = 'R', $n \geq l \geq 0$.

v (local).
REAL for pslarzb
DOUBLE PRECISION for pdlarzb
COMPLEX for pclarzb
COMPLEX*16 for pzlarzb.
Pointer into the local memory to an array of
DIMENSION(*lld_v*, *LOCc*(*jv+m-1*)) if *side* = 'L',
(*lld_v*, *LOCc*(*jv+m-1*)) if *side* = 'R'.

	<p>It contains the local pieces of the distributed vectors v representing the Householder transformation as returned by <code>p?tzrzf</code>.</p> <p>$lld_v \geq LOCr(iv+k-1)$.</p>
iv, jv	<p>(global) INTEGER.</p> <p>The row and column indices in the global array v indicating the first row and the first column of the submatrix $sub(v)$, respectively.</p>
$descv$	<p>(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix v.</p>
t	<p>(local)</p> <p>REAL for <code>pslarzb</code> DOUBLE PRECISION for <code>pdlarzb</code> COMPLEX for <code>pclarzb</code> COMPLEX*16 for <code>pzlarzb</code>.</p> <p>Array, DIMENSION mb_v by mb_v. The lower triangular matrix T in the representation of the block reflector.</p>
c	<p>(local).</p> <p>REAL for <code>pslarfb</code> DOUBLE PRECISION for <code>pdlarfb</code> COMPLEX for <code>pclarfb</code> COMPLEX*16 for <code>pzlarfb</code>.</p> <p>Pointer into the local memory to an array of DIMENSION ($lld_c, LOCc(jc+n-1)$). On entry, the m-by-n distributed matrix $sub(c)$.</p>
ic, jc	<p>(global) INTEGER.</p> <p>The row and column indices in the global array c indicating the first row and the first column of the submatrix $sub(c)$, respectively.</p>
$descc$	<p>(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix c.</p>
$work$	<p>(local).</p> <p>REAL for <code>pslarzb</code> DOUBLE PRECISION for <code>pdlarzb</code> COMPLEX for <code>pclarzb</code></p>

```

COMPLEX*16 for pzlarzb.
Array, DIMENSION (lwork).
If storev = 'C' ,
    if side = 'L' ,
        lwork ≥ (nqc0 + mpc0) * k
    else if side = 'R' ,
        lwork ≥ (nqc0 + max(npv0 + numroc(numroc(n+icoffc,
nb_v, 0, 0, npcol),
        nb_v, 0, 0, lcmq), mpc0)) * k
    end if
else if storev = 'R' ,
    if side = 'L' ,
        lwork ≥ (mpc0 + max(mqv0 + numroc(numroc(m+iroffc,
mb_v, 0, 0, nprow),
        mb_v, 0, 0, lcmp), nqc0)) * k
    else if side = 'R' ,
        lwork ≥ (mpc0 + nqc0) * k
    end if
end if.

Here lcmq = lcm/npcol with lcm = iclm(nprow,
npcol),
iroffv = mod(iv-1, mb_v), icoffv = mod( jv-1,
nb_v),
ivrow = indxg2p(iv, mb_v, myrow, rsrc_v, nprow),
ivcol = indxg2p(jv, nb_v, mycol, csrc_v, npcol),
mqv0 = numroc(m+icoffv, nb_v, mycol, ivcol,
npcol),
npv0 = numroc(n+iroffv, mb_v, myrow, ivrow,
nprow),
iroffc = mod(ic-1, mb_c ), icoffc= mod( jc-1,
nb_c),

```

```
icrow= indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol= indxg2p(jc, nb_c, mycol, csrc_c, npc0),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow,
nprow),
npc0 = numroc(n+icoffc, mb_c, myrow, icrow,
nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol,
npc0),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npc0 can be determined by
calling the subroutine blacs_gridinfo.
```

Output Parameters

c (local).
On exit, *sub(c)* is overwritten by the $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q'$, where Q' is the transpose (conjugate transpose) of Q .

p?larzc

Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tزرzf to a general matrix.

Syntax

```
call pclarzc(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

```
call pzlarzc(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau \cdot v \cdot v',$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by `p?tzzrf`.

Input Parameters

side (global) CHARACTER.
 if *side* = 'L': form $Q^H \text{sub}(C)$;
 if *side* = 'R': form $\text{sub}(C) * Q^H$.

m (global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).

n (global) INTEGER.
 The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).

l (global) INTEGER.
 The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors.
 If *side* = 'L', $m \geq l \geq 0$,
 if *side* = 'R', $n \geq l \geq 0$.

v (local).
 COMPLEX for `pclarzc`
 COMPLEX*16 for `pzlarzc`.
 Pointer into the local memory to an array of DIMENSION (*lld_v*,*) containing the local pieces of the distributed vectors v representing the Householder transformation Q ,
 $v(iv:iv+l-1, jv)$ if *side* = 'L' and *incv* = 1,
 $v(iv, jv:jv+l-1)$ if *side* = 'L' and *incv* = *m_v*,
 $v(iv:iv+l-1, jv)$ if *side* = 'R' and *incv* = 1,
 $v(iv, jv:jv+l-1)$ if *side* = 'R' and *incv* = *m_v*.
 The vector v in the representation of Q . v is not used if $\tau = 0$.

iv, jv (global) INTEGER.

	The row and column indices in the global array v indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
$descv$	(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix v .
$incv$	(global). INTEGER. The global increment for the elements of v . Only two values of $incv$ are supported in this version, namely 1 and m_v . $incv$ must not be zero.
tau	(local) COMPLEX for pclarzc COMPLEX*16 for pzlarzc. Array, DIMENSION $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix v .
c	(local). COMPLEX for pclarzc COMPLEX*16 for pzlarzc. Pointer into the local memory to an array of DIMENSION (lld_c , $LOCc(jc+n-1)$), containing the local pieces of $\text{sub}(c)$.
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix $\text{sub}(c)$, respectively.
$descc$	(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix c .

work

```
(local).
If incv = 1,
    if side = 'L' ,
        if ivcol = iccol,

            lwork ≥ nqc0

        else

            lwork ≥ mpc0 + max(1, nqc0)

        end if
    else if side = 'R' ,

        lwork ≥ nqc0 + max(max(1, mpc0),
numroc(numroc(n+icoffc, nb_v, 0, 0, npcol),
            nb_v, 0, 0, lcmq))

        end if
    else if incv = m_v,
        if side = 'L' ,

            lwork ≥ mpc0 + max(max(1, nqc0),
numroc(numroc(m+iroffc, mb_v, 0, 0, nprow),
            mb_v, 0, 0, lcmp))

        else if side = 'R',
            if ivrow = icrow,

                lwork ≥ mpc0

            else

                lwork ≥ nqc0 + max(1, mpc0)

            end if
        end if
    end if
end if
```

Here *lcm* is the least common multiple of *nprow* and *npcol*;

```
lcm = ilcm(nprow, npc0l), lcmp = lcm/nprow, lcmq =
lcm/npcol,
iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1,
nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npc0l),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow,
nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol,
npc0l),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npc0l can be determined by
calling the subroutine blacs_gridinfo.
```

Output Parameters

c

(local).

On exit, $\text{sub}(c)$ is overwritten by the $Q^H * \text{sub}(C)$ if *side* = 'L', or $\text{sub}(C) * Q^H$ if *side* = 'R'.

p?larzt

*Forms the triangular factor T of a block reflector $H = I - V * T * V^H$ as returned by p?tzzrf.*

Syntax

```
call pslarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzlarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine forms the triangular factor T of a real/complex block reflector H of order greater than n , which is defined as a product of k elementary reflectors as returned by `p?tzzrf`.

If *direct* = 'F', $H = H(1) * H(2) * \dots * H(k)$, and T is upper triangular;

If $direct = 'B'$, $H = H(k) * \dots * H(2) * H(1)$, and T is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$, is stored in the i -th column of the array v , and

$$H = I - v * t * v'.$$

If $storev = 'R'$, the vector, which defines the elementary reflector $H(i)$, is stored in the i -th row of the array v , and

$$H = I - v' * t * v$$

Currently, only $storev = 'R'$ and $direct = 'B'$ are supported.

Input Parameters

<i>direct</i>	(global) CHARACTER. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if $direct = 'F'$: $H = H(1) * H(2) * \dots * H(k)$ (Forward, not supported) if $direct = 'B'$: $H = H(k) * \dots * H(2) * H(1)$ (Backward).
<i>storev</i>	(global) CHARACTER. Specifies how the vectors which defines the elementary reflectors are stored: if $storev = 'C'$: columnwise (not supported); if $storev = 'R'$: rowwise.
<i>n</i>	(global). INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	(global). INTEGER. The order of the triangular factor T (= the number of elementary reflectors). $1 \leq k \leq mb_v (= nb_v)$.
<i>v</i>	REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Pointer into the local memory to an array of local DIMENSION($LOCr(iv+k-1)$, $LOCc(jv+n-1)$).

	The distributed matrix v contains the Householder vectors. See <i>Application Notes</i> below.
iv, jv	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
$descv$	(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix v .
τ	(local) REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Array, DIMENSION $LOCr(iv+k-1)$ if $incv = m_v$, and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. τ is tied to the distributed matrix v .
$work$	(local). REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Workspace array, DIMENSION $(k*(k-1)/2)$.

Output Parameters

v	REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt.
t	(local) REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Array, DIMENSION (mb_v, mb_v). It contains the k -by- k triangular factor of the block reflector associated with v . t is lower triangular.

Application Notes

The shape of the matrix v and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct='F' and storev='C'

$$v = \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

$$v = \begin{bmatrix} . & . & . \\ . & . & . \\ 1 & . & . \\ . & 1 & . \\ . & . & 1 \end{bmatrix}$$

direct='F' and storev='R'

$$\begin{bmatrix} \overbrace{v1 \ v1 \ v1 \ v1 \ v1}^v & . & . & . & 1 \\ v2 \ v2 \ v2 \ v2 \ v2 & . & . & . & 1 \\ v3 \ v3 \ v3 \ v3 \ v3 & . & . & . & 1 \end{bmatrix}$$

direct='B' and storev='C'

$$v = \begin{bmatrix} 1 \\ . & 1 \\ . & . & 1 \\ . & . & . \\ . & . & . \end{bmatrix}$$

$$\begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

direct='B' and storev='R':

$$\begin{bmatrix} 1 & . & . & . & \overbrace{.v1 \ v1 \ v1 \ v1 \ v1}^v \\ . & 1 & . & . & .v2 \ v2 \ v2 \ v2 \ v2 \\ . & . & 1 & . & .v3 \ v3 \ v3 \ v3 \ v3 \end{bmatrix}$$

p?lascl

Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from}

Syntax

```
call pslascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pdlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pclascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pzlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine multiplies the m -by- n real/complex distributed matrix `sub(A)` denoting $A(ia:ia+m-1, ja:ja+n-1)$ by the real/complex scalar $cto/cfrom$. This is done without over/underflow as long as the final result $cto*A(i, j)/cfrom$ does not over/underflow. *type* specifies that `sub(A)` may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

type (global) CHARACTER.
type indicates the storage type of the input distributed matrix.
 if *type* = 'G': `sub(A)` is a full matrix,
 if *type* = 'L': `sub(A)` is a lower triangular matrix,
 if *type* = 'U': `sub(A)` is an upper triangular matrix,
 if *type* = 'H': `sub(A)` is an upper Hessenberg matrix.

<i>cfrom, cto</i>	<p>(global)</p> <p>REAL for pslascl/pclascl DOUBLE PRECISION for pdlascl/pzlascl.</p> <p>The distributed matrix sub(<i>A</i>) is multiplied by <i>cto/cfrom</i>. <i>A</i>(<i>i,j</i>) is computed without over/underflow if the final result <i>cto</i>*<i>A</i>(<i>i,j</i>) / <i>cfrom</i> can be represented without over/underflow. <i>cfrom</i> must be nonzero.</p>
<i>m</i>	<p>(global) INTEGER.</p> <p>The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>A</i>). (<i>m</i>≥0).</p>
<i>n</i>	<p>(global) INTEGER.</p> <p>The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(<i>A</i>). (<i>n</i>≥0).</p>
<i>a</i>	<p>(local input/local output)</p> <p>REAL for pslascl DOUBLE PRECISION for pdlascl COMPLEX for pcascl COMPLEX*16 for pzlascl.</p> <p>Pointer into the local memory to an array of DIMENSION(<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)). This array contains the local pieces of the distributed matrix sub(<i>A</i>).</p>
<i>ia, ja</i>	<p>(global) INTEGER.</p> <p>The column and row indices in the global array <i>A</i> indicating the first row and column of the submatrix sub(<i>A</i>), respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER .</p> <p>Array of DIMENSION (<i>dlen_</i>).The array descriptor for the distributed matrix <i>A</i>.</p>

Output Parameters

<i>a</i>	<p>(local).</p> <p>On exit, this array contains the local pieces of the distributed matrix multiplied by <i>cto/cfrom</i>.</p>
<i>info</i>	<p>(local)</p>

INTEGER.
 if *info* = 0: the execution is successful.
 if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$,
 if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

p?laset

Initializes the offdiagonal elements of a matrix to alpha and the diagonal elements to beta.

Syntax

```
call pslaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pdlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pclaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pzlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine initializes an *m*-by-*n* distributed matrix sub(*A*) denoting *A*(*ia:ia+m-1*, *ja:ja+n-1*) to *beta* on the diagonal and *alpha* on the offdiagonals.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the part of the distributed matrix sub(<i>A</i>) to be set: if <i>uplo</i> = 'U': upper triangular part; the strictly lower triangular part of sub(<i>A</i>) is not changed; if <i>uplo</i> = 'L': lower triangular part; the strictly upper triangular part of sub(<i>A</i>) is not changed. Otherwise: all of the matrix sub(<i>A</i>) is set.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>A</i>). ($m \geq 0$).
<i>n</i>	(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$.
 $(n \geq 0)$.

alpha (global).
 REAL for pslaset
 DOUBLE PRECISION for pdlaset
 COMPLEX for pclaset
 COMPLEX*16 for pzlaset.
 The constant to which the offdiagonal elements are to be set.

beta (global).
 REAL for pslaset
 DOUBLE PRECISION for pdlaset
 COMPLEX for pclaset
 COMPLEX*16 for pzlaset.
 The constant to which the diagonal elements are to be set.

Output Parameters

a (local).
 REAL for pslaset
 DOUBLE PRECISION for pdlaset
 COMPLEX for pclaset
 COMPLEX*16 for pzlaset.
 Pointer into the local memory to an array of
 DIMENSION(*lld_a*, *LOCc(ja+n-1)*).
 This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading m -by- n submatrix $\text{sub}(A)$ is set as follows:

if *uplo* = 'U', $A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq j-1,$
 $1 \leq j \leq n,$

if *uplo* = 'L', $A(ia+i-1, ja+j-1) = \alpha, j+1 \leq i \leq m,$
 $1 \leq j \leq n,$

otherwise, $A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq m, 1 \leq j \leq n,$
 $ia+i.ne.ja+j,$ and, for all *uplo*, $A(ia+i-1, ja+i-1) =$
 $\beta, 1 \leq i \leq \min(m, n).$

<i>ia, ja</i>	(global) INTEGER. The column and row indices in the global array <i>A</i> indicating the first row and column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER . Array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

```
call pslasmsub(a, desca, i, l, k, smlnum, buf, lwork)
call pdlasmsub(a, desca, i, l, k, smlnum, buf, lwork)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This routine does a global maximum and must be called by all processes.

Input Parameters

<i>a</i>	(global) REAL for pslasmsub DOUBLE PRECISION for pdlasmsub Array, DIMENSION (<i>desca(lld_)</i> , *). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER. Array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>i</i>	(global) INTEGER. The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>l</i>	(global) INTEGER.

The global location of the top of the unreduced submatrix of A .
 Unchanged on exit.

smlnum (global)
 REAL for pslasmsub
 DOUBLE PRECISION for pdlasmsub
 On entry, a “small number” for the given matrix. Unchanged on exit.

lwork (global) INTEGER.
 On exit, *lwork* is the size of the work buffer.
 This must be at least $2 * \text{ceil}(\text{ceil}((i-1)/hbl) / \text{lcm}(nprow, npcold))$. Here *lcm* is least common multiple, and $nprow \times npcold$ is the logical grid size.

Output Parameters

k (global) INTEGER.
 On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $l \leq m \leq i-1$.

buf (local).
 REAL for pslasmsub
 DOUBLE PRECISION for pdlasmsub
 Array of size *lwork*.

p?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call pslasq(n, x, ix, jx, descx, incx, scale, sumsq)
call pdlasq(n, x, ix, jx, descx, incx, scale, sumsq)
call pclasq(n, x, ix, jx, descx, incx, scale, sumsq)
call pzlasq(n, x, ix, jx, descx, incx, scale, sumsq)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine returns the values `scl` and `sumsq` such that

$$scl^2 * sumsq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = \text{sub}(X) = X(ix + (jx-1)*descx(m_) + (i - 1)*incx)$ for `plassq/pdlassq`,

and $x(i) = \text{sub}(X) = \text{abs}(X(ix + (jx-1)*descx(m_) + (i - 1)*incx))$ for `pclassq/pzlassq`.

For real routines `plassq/pdlassq` the value of `sumsq` is assumed to be non-negative and `scl` returns the value

$$scl = \max(scale, \text{abs}(x(i))).$$

For complex routines `pclassq/pzlassq` the value of `sumsq` is assumed to be at least unity and the value of `ssq` will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value `scale` is assumed to be non-negative and `scl` returns the value

$$scl = \max_i \left(scale, \text{abs}(\text{real}(x(i))), \text{abs}(\text{aimag}(x(i))) \right)$$

For all routines `p?lassq` values `scale` and `sumsq` must be supplied in `scale` and `sumsq` respectively, and `scale` and `sumsq` are overwritten by `scl` and `ssq` respectively.

All routines `p?lassq` make only one pass through the vector `sub(x)`.

Input Parameters

<code>n</code>	(global) INTEGER. The length of the distributed vector <code>sub(x)</code> .
<code>x</code>	REAL for <code>plassq</code> DOUBLE PRECISION for <code>pdlassq</code> COMPLEX for <code>pclassq</code> COMPLEX*16 for <code>pzlassq</code> . The vector for which a scaled sum of squares is computed:

	$x(ix + (jx-1)*m_x + (i - 1)*incx), 1 \leq i \leq n.$
<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of sub(<i>x</i>).
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of sub(<i>x</i>).
<i>descx</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. The global increment for the elements of <i>x</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> . The argument <i>incx</i> must not equal zero.
<i>scale</i>	(local). REAL for psllassq/pclassq DOUBLE PRECISION for pdlassq/pzlassq. On entry, the value <i>scale</i> in the equation above.
<i>sumsq</i>	(local) REAL for psllassq/pclassq DOUBLE PRECISION for pdlassq/pzlassq. On entry, the value <i>sumsq</i> in the equation above.

Output Parameters

<i>scale</i>	(local). On exit, <i>scale</i> is overwritten with <i>scl</i> , the scaling factor for the sum of squares.
<i>sumsq</i>	(local). On exit, <i>sumsq</i> is overwritten with the value <i>smsq</i> , the basic sum of squares from which <i>scl</i> has been factored out.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call pslaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pdlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pclaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pzlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine performs a series of row or column interchanges on the distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$. One interchange is initiated for each of rows or columns $k1$ through $k2$ of $\text{sub}(A)$. This routine assumes that the pivoting information has already been broadcast along the process row or column. Also note that this routine will only work for $k1-k2$ being in the same *mb* (or *nb*) block. If you want to pivot a full matrix, use [p?lapiv](#).

Input Parameters

<i>direc</i>	(global) CHARACTER. Specifies in which order the permutation is applied: = 'F' - forward, = 'B' - backward.
<i>rowcol</i>	(global) CHARACTER. Specifies if the rows or columns are permuted: = 'R' - rows, = 'C' - columns.
<i>n</i>	(global) INTEGER. If <i>rowcol</i> ='R', the length of the rows of the distributed matrix $A(*, ja:ja+n-1)$ to be permuted; If <i>rowcol</i> ='C', the length of the columns of the distributed matrix $A(ia:ia+n-1, *)$ to be permuted;
<i>a</i>	(local) REAL for pslaswp

DOUBLE PRECISION for pdlaswp
 COMPLEX for pclaswp
 COMPLEX*16 for pzlaswp.
 Pointer into the local memory to an array of DIMENSION
 (*lld_a*, *). On entry, this array contains the local pieces of
 the distributed matrix to which the row/columns
 interchanges will be applied.

ia (global) INTEGER.
 The row index in the global array *A* indicating the first row
 of sub(*A*).

ja (global) INTEGER.
 The column index in the global array *A* indicating the first
 column of sub(*A*).

desca (global and local) INTEGER array of DIMENSION (*dlen_*).
 The array descriptor for the distributed matrix *A*.

k1 (global) INTEGER.
 The first element of *ipiv* for which a row or column
 interchange will be done.

k2 (global) INTEGER.
 The last element of *ipiv* for which a row or column
 interchange will be done.

ipiv (local)
 INTEGER. Array, DIMENSION *LOCr(m_a)+mb_a* for row
 pivoting and *LOCr(n_a)+nb_a* for column pivoting. This
 array is tied to the matrix *A*, *ipiv*(*k*)=*l* implies rows (or
 columns) *k* and *l* are to be interchanged.

Output Parameters

A (local)
 REAL for pslaswp
 DOUBLE PRECISION for pdlaswp
 COMPLEX for pclaswp
 COMPLEX*16 for pzlaswp.
 On exit, the permuted distributed matrix.

p?latra

Computes the trace of a general square distributed matrix.

Syntax

```
val = pslatra(n, a, ia, ja, desca)
val = pdlatra(n, a, ia, ja, desca)
val = pclatra(n, a, ia, ja, desca)
val = pzlatra(n, a, ia, ja, desca)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This function computes the trace of an n -by- n distributed matrix `sub(A)` denoting `A(ia:ia+n-1, ja:ja+n-1)`. The result is left on every process of the grid.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix <code>sub(A)</code> . $n \geq 0$.
<i>a</i>	(local). Real for <code>pslatra</code> DOUBLE PRECISION for <code>pdlatra</code> COMPLEX for <code>pclatra</code> COMPLEX*16 for <code>pzlatra</code> . Pointer into the local memory to an array of <code>DIMENSION(11d_a, LOCc(ja+n-1))</code> containing the local pieces of the distributed matrix, the trace of which is to be computed.
<i>ia, ja</i>	(global) INTEGER. The row and column indices respectively in the global array <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) INTEGER array of <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix <code>A</code> .

Output Parameters

`val` The value returned by the fuction.

p?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call pslatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pdlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pclatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pzlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine reduces nb rows and columns of a real symmetric or complex Hermitian matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation $Q'^* \text{sub}(A) Q$, and returns the matrices V and W , which are needed to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $uplo = U$, `p?latrd` reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if $uplo = L$, `p?latrd` reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by `p?sytrd/p?hetrd`.

Input Parameters

`uplo` (global) CHARACTER.
 Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored:
 = 'U': Upper triangular
 = L: Lower triangular.

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>nb</i>	(global) INTEGER. The number of rows and columns to be reduced.
<i>a</i>	REAL for pslatrd DOUBLE PRECISION for pdlatrd COMPLEX for pclatrd COMPLEX*16 for pzlatrd. Pointer into the local memory to an array of DIMENSION(<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = U, the leading <i>n</i> -by- <i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = L, the leading <i>n</i> -by- <i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of $\text{sub}(A)$.
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of $\text{sub}(A)$.
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iw</i>	(global) INTEGER. The row index in the global array <i>W</i> indicating the first row of $\text{sub}(W)$.
<i>jw</i>	(global) INTEGER. The column index in the global array <i>W</i> indicating the first column of $\text{sub}(W)$.
<i>descw</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>W</i> .
<i>work</i>	(local)

REAL for pslatrd
 DOUBLE PRECISION for pdlatrd
 COMPLEX for pclatrd
 COMPLEX*16 for pzlatrd.
 Workspace array of DIMENSION (nb_a).

Output Parameters

a (local)
 On exit, if $uplo = 'U'$, the last nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $sub(A)$; the elements above the diagonal with the array τ represent the orthogonal/unitary matrix Q as a product of elementary reflectors;
 if $uplo = 'L'$, the first nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $sub(A)$; the elements below the diagonal with the array τ represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

d (local)
 REAL for pslatrd/pclatrd
 DOUBLE PRECISION for pdlatrd/pzlatrd.
 Array, DIMENSION $LOCc(ja+n-1)$.
 The diagonal elements of the tridiagonal matrix T : $d(i) = a(i, i)$. d is tied to the distributed matrix A .

e (local)
 REAL for pslatrd/pclatrd
 DOUBLE PRECISION for pdlatrd/pzlatrd.
 Array, DIMENSION $LOCc(ja+n-1)$ if $uplo = 'U'$, $LOCc(ja+n-2)$ otherwise.
 The off-diagonal elements of the tridiagonal matrix T :
 $e(i) = a(i, i + 1)$ if $uplo = 'U'$,
 $e(i) = a(i + 1, i)$ if $uplo = L$.
 e is tied to the distributed matrix A .

tau (local)
 REAL for pslatrd
 DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd
 COMPLEX*16 for pzlatrd.
 Array, DIMENSION $LOCc(ja+n-1)$. This array contains the scalar factors τ of the elementary reflectors. τ is tied to the distributed matrix A .

w (local)
 REAL for pslatrd
 DOUBLE PRECISION for pdlatrd
 COMPLEX for pclatrd
 COMPLEX*16 for pzlatrd.
 Pointer into the local memory to an array of DIMENSION (lld_w, nb_w) . This array contains the local pieces of the n -by- nb_w matrix w required to update the unreduced part of $sub(A)$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-1, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1: ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The elements of the vectors v together form the n -by- nb matrix V which is needed, with w , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$ update of the form:

$$sub(A) := sub(A) - v w^T - w v^T.$$

The contents of a on exit are illustrated by the following examples with

$n = 5$ and $nb = 2$:

$$\begin{array}{ll} \text{if } \text{uplo}='U': & \text{if } \text{uplo}='L': \\ \begin{bmatrix} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{bmatrix} & \begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{bmatrix} \end{array}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

p?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

```
call pslatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

```
call pdlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

```
call pclatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

```
call pzlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine solves a triangular system of equations $Ax = sb$, $A^T x = sb$ or $A^H x = sb$, where s is a scale factor set to prevent overflow. The description of the routine will be extended in the future releases.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the matrix <i>A</i> is upper or lower triangular.</p> <p>= 'U': Upper triangular</p> <p>= 'L': Lower triangular</p>
<i>trans</i>	<p>CHARACTER*1.</p> <p>Specifies the operation applied to Ax.</p> <p>= 'N': Solve $Ax = s*b$ (no transpose)</p> <p>= 'T': Solve $A^T x = s*b$ (transpose)</p> <p>= 'C': Solve $A^H x = s*b$ (conjugate transpose), where <i>s</i> - is a scale factor</p>
<i>diag</i>	<p>CHARACTER*1.</p> <p>Specifies whether or not the matrix <i>A</i> is unit triangular.</p> <p>= 'N': Non-unit triangular</p> <p>= 'U': Unit triangular</p>
<i>normin</i>	<p>CHARACTER*1.</p> <p>Specifies whether <i>cnorm</i> has been set or not.</p> <p>= 'Y': <i>cnorm</i> contains the column norms on entry;</p> <p>= 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i>.</p>
<i>n</i>	<p>INTEGER.</p> <p>The order of the matrix <i>A</i>. $n \geq 0$</p>
<i>a</i>	<p>REAL for pslatrs/pclatrs</p> <p>DOUBLE PRECISION for pdlatrs/pzlatrs</p> <p>Array, DIMENSION (<i>lda</i>, <i>n</i>). Contains the triangular matrix <i>A</i>.</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced.</p> <p>If <i>diag</i> = 'U', the diagonal elements of <i>a</i> are also not referenced and are assumed to be 1.</p>

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>x</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs Array, DIMENSION (<i>n</i>). On entry, the right hand side <i>b</i> of the triangular system.
<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of sub(<i>x</i>).
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of sub(<i>x</i>).
<i>descx</i>	(global and local) INTEGER. Array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i> .
<i>cnorm</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs. Array, DIMENSION (<i>n</i>). If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i> (<i>j</i>) contains the norm of the off-diagonal part of the <i>j</i> -th column of <i>A</i> . If <i>trans</i> = 'N', <i>cnorm</i> (<i>j</i>) must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm</i> (<i>j</i>) must be greater than or equal to the 1-norm.
<i>work</i>	(local). REAL for pslatrs DOUBLE PRECISION for pdlatrs COMPLEX for pclatrs COMPLEX*16 for pzlatrs. Temporary workspace.

Output Parameters

<i>x</i>	On exit, <i>x</i> is overwritten by the solution vector <i>x</i> .
<i>scale</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs.

Array, DIMENSION (lda, n). The scaling factor s for the triangular system as described above.

If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $Ax = 0$.

$cnorm$

If $normin = 'N'$, $cnorm$ is an output argument and $cnorm(j)$ returns the 1-norm of the off-diagonal part of the j -th column of A .

p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

Syntax

```
call pslatz(m, n, l, a, ia, ja, desca, tau, work)
```

```
call pdlatrz(m, n, l, a, ia, ja, desca, tau, work)
```

```
call pclatz(m, n, l, a, ia, ja, desca, tau, work)
```

```
call pzlatrz(m, n, l, a, ia, ja, desca, tau, work)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $sub(A) = [A(ia:ia+m-1, ja:ja+m-1) A(ia:ia+m-1, ja+n-l:ja+n-1)]$ to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix $sub(A)$ is factored as

$$sub(A) = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $sub(A)$. $m \geq 0$.

<i>n</i>	<p>(global) INTEGER.</p> <p>The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.</p>
<i>l</i>	<p>(global) INTEGER.</p> <p>The number of columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. $l > 0$.</p>
<i>a</i>	<p>(local)</p> <p>REAL for pslatz DOUBLE PRECISION for pdlatrz COMPLEX for pclatz COMPLEX*16 for pzlatrz.</p> <p>Pointer into the local memory to an array of $\text{DIMENSION}(lld_a, LOCC(ja+n-1))$. On entry, the local pieces of the m-by-n distributed matrix $\text{sub}(A)$, which is to be factored.</p>
<i>ia</i>	<p>(global) INTEGER.</p> <p>The row index in the global array <i>A</i> indicating the first row of $\text{sub}(A)$.</p>
<i>ja</i>	<p>(global) INTEGER.</p> <p>The column index in the global array <i>A</i> indicating the first column of $\text{sub}(A)$.</p>
<i>desca</i>	<p>(global and local) INTEGER array of $\text{DIMENSION}(dlen_)$.</p> <p>The array descriptor for the distributed matrix <i>A</i>.</p>
<i>work</i>	<p>(local)</p> <p>REAL for pslatz DOUBLE PRECISION for pdlatrz COMPLEX for pclatz COMPLEX*16 for pzlatrz.</p> <p>Workspace array, $\text{DIMENSION}(lwork)$.</p> <p>$lwork \geq nq0 + \max(1, mp0)$, where</p> <p>$iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$,</p>

`mp0 = numroc(m+iroff, mb_a, myrow, iarow, nprow),`
`nq0 = numroc(n+icoff, nb_a, mycol, iacol, npc0l),`
`numroc, indxg2p, and numroc` are ScaLAPACK tool
 functions; `myrow, mycol, nprow, and npc0l` can be
 determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

<i>a</i>	On exit, the leading m -by- m upper triangular part of <code>sub(A)</code> contains the upper triangular matrix R , and elements $n-l+1$ to n of the first m rows of <code>sub(A)</code> , with the array <i>tau</i> , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors.
<i>tau</i>	(local) REAL for <code>pslatrz</code> DOUBLE PRECISION for <code>pdlatz</code> COMPLEX for <code>pclatz</code> COMPLEX*16 for <code>pzlatrz</code> . Array, <code>DIMENSION (LOCr(ja+m-1))</code> . This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix A .

Application Notes

The factorization is obtained by Householder's method. The k -th transformation matrix, $Z(k)$, which is used (or, in case of complex routines, whose conjugate transpose is used) to introduce zeros into the $(m - k + 1)$ -th row of `sub(A)`, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{bmatrix} I \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an $(n-m)$ -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $z(k)$ are in $a(k, m+1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$.

Z is given by

$$Z = Z(1)Z(2)\dots Z(m).$$

p?lauu2

*Computes the product U^*U' or L'^*L , where U and L are upper or lower triangular matrices (local unblocked algorithm).*

Syntax

```
call pslauu2(uplo, n, a, ia, ja, desca)
call pdlauu2(uplo, n, a, ia, ja, desca)
call pclauu2(uplo, n, a, ia, ja, desca)
call pzlauu2(uplo, n, a, ia, ja, desca)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes the product U^*U' or L'^*L , where the triangular factor U or L is stored in the upper or lower triangular part of the distributed matrix

$\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$.

If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this routine, the matrix to operate on should be strictly local to one process.

Input Parameters

$uplo$ (global) CHARACTER*1.

Specifies whether the triangular factor stored in the *matrix* `sub(A)` is upper or lower triangular:

= U: upper triangular

= L: lower triangular.

n

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the triangular factor *U* or *L*. $n \geq 0$.

a

(local)

REAL for `pslauu2`

DOUBLE PRECISION for `pdlauu2`

COMPLEX for `pclauu2`

COMPLEX*16 for `pzlauu2`.

Pointer into the local memory to an array of

`DIMENSION (lld_a, LOcc(ja+n-1))`. On entry, the local pieces of the triangular factor *U* or *L*.

ia

(global) INTEGER.

The row index in the global array *A* indicating the first row of `sub(A)`.

ja

(global) INTEGER.

The column index in the global array *A* indicating the first column of `sub(A)`.

desca

(global and local) INTEGER array of `DIMENSION (dlen_)`.

The array descriptor for the distributed matrix *A*.

Output Parameters

a

(local)

On exit, if `uplo = 'U'`, the upper triangle of the distributed matrix `sub(A)` is overwritten with the upper triangle of the product $U*U'$; if `uplo = 'L'`, the lower triangle of `sub(A)` is overwritten with the lower triangle of the product $L*L$.

p?lauum

*Computes the product $U*U'$ or $L'*L$, where U and L are upper or lower triangular matrices.*

Syntax

```
call pslauum(uplo, n, a, ia, ja, desca)
call pdlauum(uplo, n, a, ia, ja, desca)
call pclauum(uplo, n, a, ia, ja, desca)
call pzlauum(uplo, n, a, ia, ja, desca)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the product $U*U'$ or $L'*L$, where the triangular factor U or L is stored in the upper or lower triangular part of the matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$. If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

$uplo$	(global) CHARACTER*1. Specifies whether the triangular factor stored in the matrix $\text{sub}(A)$ is upper or lower triangular: = 'U': upper triangular = 'L': lower triangular.
n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the triangular factor U or L . $n \geq 0$.
a	(local) REAL for pslauum DOUBLE PRECISION for pdlauum COMPLEX for pclauum COMPLEX*16 for pzlauum.

	Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOCC(ja+n-1))</code> . On entry, the local pieces of the triangular factor U or L .
<code>ia</code>	(global) INTEGER. The row index in the global array A indicating the first row of <code>sub(A)</code> .
<code>ja</code>	(global) INTEGER. The column index in the global array A indicating the first column of <code>sub(A)</code> .
<code>desca</code>	(global and local) INTEGER array of <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix A .

Output Parameters

<code>a</code>	(local) On exit, if <code>uplo = 'U'</code> , the upper triangle of the distributed matrix <code>sub(A)</code> is overwritten with the upper triangle of the product $U*U'$; if <code>uplo = 'L'</code> , the lower triangle of <code>sub(A)</code> is overwritten with the lower triangle of the product $L'*L$.
----------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

p?lawil

Forms the Wilkinson transform.

Syntax

```
call pslawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
call pdlawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine gets the transform given by `h44`, `h33`, and `h43h34` into `v` starting at row `m`.

Input Parameters

<code>ii</code>	(global) INTEGER. Row owner of $h(m+2, m+2)$.
<code>jj</code>	(global) INTEGER.

	Column owner of $h(m+2, m+2)$.
m	(global) INTEGER. On entry, the location from where the transform starts (row m). Unchanged on exit.
a	(global) REAL for pslawil DOUBLE PRECISION for pdlawil Array, DIMENSION ($desca(lld_)$, *). On entry, the Hessenberg matrix. Unchanged on exit.
$desca$	(global and local) INTEGER Array of DIMENSION ($dlen_$). The array descriptor for the distributed matrix A . Unchanged on exit.
$h43h34$	(global) REAL for pslawil DOUBLE PRECISION for pdlawil These three values are for the double shift QR iteration. Unchanged on exit.

Output Parameters

v	(global) REAL for pslawil DOUBLE PRECISION for pdlawil Array of size 3 that contains the transform on output.
-----	------------------------------------------------------------------------------------------------------------------------

p?org2l/p?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

```
call psorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine `p?org2l/p?ung2l` generates an m -by- n real/complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m :

$Q = H(k) * \dots * H(2) * H(1)$ as returned by `p?geqlf`.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $m \geq n \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	REAL for <code>psorg2l</code> DOUBLE PRECISION for <code>pdorg2l</code> COMPLEX for <code>pcung2l</code> COMPLEX*16 for <code>pzung2l</code> . Pointer into the local memory to an array, DIMENSION (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). On entry, the j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by <code>p?geqlf</code> in the k columns of its <i>distributed matrix</i> argument $A(ia:*, ja+n-k:ja+n-1)$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of sub(A).
ja	(global) INTEGER. The column index in the global array A indicating the first column of sub(A).

desca (global and local) INTEGER array of DIMENSION (*dlen_*).
The array descriptor for the distributed matrix *A*.

tau (local)
REAL for *psorg2l*
DOUBLE PRECISION for *pdorg2l*
COMPLEX for *pcung2l*
COMPLEX*16 for *pzung2l*.
Array, DIMENSION *LOCc(ja+n-1)*.
This array contains the scalar factor *tau(j)* of the elementary reflector $H(j)$, as returned by [p?geqlf](#).

work (local)
REAL for *psorg2l*
DOUBLE PRECISION for *pdorg2l*
COMPLEX for *pcung2l*
COMPLEX*16 for *pzung2l*.
Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where
 $iroffa = \text{mod}(ia-1, mb_a),$
 $icoffa = \text{mod}(ja-1, nb_a),$
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow),$
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcold),$
 $mpa0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow),$
 $nqa0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcold).$
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine [blacs_gridinfo](#).
If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	On exit, this array contains the local pieces of the m -by- n distributed matrix Q .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the i -th argument is an array and the j -entry had an illegal value, then <i>info</i> = - ($i*100 + j$), if the i -th argument is a scalar and had an illegal value, then <i>info</i> = - i .

p?org2r/p?ung2r

Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).

Syntax

```
call psorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine p?org2r/p?ung2r generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m :

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by p?geqrf.

Input Parameters

m (global) INTEGER.

	<p>The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q. $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER.</p> <p>The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q. $m \geq n \geq 0$.</p>
<i>k</i>	<p>(global) INTEGER.</p> <p>The number of elementary reflectors whose product defines the matrix Q. $n \geq k \geq 0$.</p>
<i>a</i>	<p>REAL for psorg2r DOUBLE PRECISION for pdorg2r COMPLEX for pcung2r COMPLEX*16 for pzung2r.</p> <p>Pointer into the local memory to an array, DIMENSION(<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)).</p> <p>On entry, the <i>j</i>-th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the <i>k</i> columns of its <i>distributed matrix</i> argument $A(ia:*, ja:ja+k-1)$.</p>
<i>ia</i>	<p>(global) INTEGER.</p> <p>The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).</p>
<i>ja</i>	<p>(global) INTEGER.</p> <p>The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array of DIMENSION (<i>dlen_</i>).</p> <p>The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for psorg2r DOUBLE PRECISION for pdorg2r COMPLEX for pcung2r COMPLEX*16 for pzung2r.</p> <p>Array, DIMENSION <i>LOCc</i>(<i>ja</i>+<i>k</i>-1).</p>

This array contains the scalar factor $\tau(j)$ of the elementary reflector $H(j)$, as returned by [p?geqrf](#). This array is tied to the distributed matrix A .

work (local)
 REAL for psorg2r
 DOUBLE PRECISION for pdorg2r
 COMPLEX for pcung2r
 COMPLEX*16 for pzung2r.
 Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$,
 where
 $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$,
 $mpa0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$,
 $nqa0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcot)$.
 indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a On exit, this array contains the local pieces of the m -by- n distributed matrix Q .

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.

= 0: successful exit
 < 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $info = - (i*100+j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

p?orgl2/p?ungl2

Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).

Syntax

```
call psorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine p?orgl2/p?ungl2 generates a m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = H(k) * \dots * H(2) * H(1)$ (for real flavors),

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ (for complex flavors) as returned by p?gelqf.

Input Parameters

m (global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.

n (global) INTEGER.
 The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $n \geq m \geq 0$.

<i>k</i>	<p>(global) INTEGER.</p> <p>The number of elementary reflectors whose product defines the matrix Q. $m \geq k \geq 0$.</p>
<i>a</i>	<p>REAL for psorgl2 DOUBLE PRECISION for pdorgl2 COMPLEX for pcungl2 COMPLEX*16 for pzungl2.</p> <p>Pointer into the local memory to an array, DIMENSION (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)).</p> <p>On entry, the <i>i</i>-th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the <i>k</i> rows of its <i>distributed matrix</i> argument $A(ia:ia+k-1, ja:*)$.</p>
<i>ia</i>	<p>(global) INTEGER.</p> <p>The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).</p>
<i>ja</i>	<p>(global) INTEGER.</p> <p>The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array of DIMENSION (<i>dlen_</i>).</p> <p>The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for psorgl2 DOUBLE PRECISION for pdorgl2 COMPLEX for pcungl2 COMPLEX*16 for pzungl2.</p> <p>Array, DIMENSION <i>LOCr</i>(<i>ja</i>+<i>k</i>-1). This array contains the scalar factors <i>tau</i>(<i>i</i>) of the elementary reflectors $H(i)$, as returned by p?gelqf. This array is tied to the distributed matrix <i>A</i>.</p>
<i>WORK</i>	<p>(local)</p> <p>REAL for psorgl2 DOUBLE PRECISION for pdorgl2 COMPLEX for pcungl2 COMPLEX*16 for pzungl2.</p> <p>Workspace array, DIMENSION (<i>lwork</i>).</p>

lwork

(local or global) INTEGER.

The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where

$$iroffa = \text{mod}(ia-1, mb_a),$$

$$icoffa = \text{mod}(ja-1, nb_a),$$

$$iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow),$$

$$iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot),$$

$$mpa0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow),$$

$$nqa0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcot).$$

indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcot* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,

then *info* = - (*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

p?orgr2/p?ungr2

Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).

Syntax

```
call psorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine p?orgr2/p?ungr2 generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1) * H(2) * \dots * H(k)$ (for real flavors);

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ (for complex flavors) as returned by p?gerqf.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $n \geq m \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for psorgr2 DOUBLE PRECISION for pdorgr2 COMPLEX for pcungr2

COMPLEX*16 for pzungr2.
 Pointer into the local memory to an array,
 DIMENSION (*lld_a*, *LOCc(ja+n-1)*).
 On entry, the *i*-th row must contain the vector that defines
 the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$,
 as returned by [p?gerqf](#) in the *k* rows of its *distributed*
matrix argument $A(ia+m-k:ia+m-1, ja:*)$.

ia (global) INTEGER.
 The row index in the global array *A* indicating the first row
 of sub(*A*).

ja (global) INTEGER.
 The column index in the global array *A* indicating the first
 column of sub(*A*).

desca (global and local) INTEGER array of DIMENSION (*dlen_*).
 The array descriptor for the distributed matrix *A*.

tau (local)
 REAL for psorgr2
 DOUBLE PRECISION for pdorgr2
 COMPLEX for pcungr2
 COMPLEX*16 for pzungr2.
 Array, DIMENSION *LOCr(ja+m-1)*. This array contains the
 scalar factors *tau(i)* of the elementary reflectors $H(i)$, as
 returned by [p?gerqf](#). This array is tied to the distributed
 matrix *A*.

work (local)
 REAL for psorgr2
 DOUBLE PRECISION for pdorgr2
 COMPLEX for pcungr2
 COMPLEX*16 for pzungr2.
 Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
 The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 +$
 $\max(1, mpa0)$, where $iroffa = \text{mod}(ia-1, mb_a)$,
 $icoffa = \text{mod}(ja-1, nb_a)$,

```

iarow = indxg2p( ia, mb_a, myrow, rsrc_a, nprow
),
iacol = indxg2p( ja, nb_a, mycol, csrc_a, npcol
),
mpa0 = numroc( m+iroffa, mb_a, myrow, iarow,
nprow ),
nqa0 = numroc( n+icoffa, nb_a, mycol, iacol,
npcol ).

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	On exit, this array contains the local pieces of the m -by- n distributed matrix Q .
<code>work</code>	On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	<p>(local) INTEGER.</p> <p>= 0: successful exit</p> <p>< 0: if the i-th argument is an array and the j-entry had an illegal value,</p> <p>then <code>info = - (i*100+j)</code>,</p> <p>if the i-th argument is a scalar and had an illegal value,</p> <p>then <code>info = -i</code>.</p>

p?orm2l/p?unm2l

Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

```
call psorm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdorm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pcunm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine p?orm2l/p?unm2l overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1,jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C)*Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k)*\dots*H(2)*H(1)$ as returned by p?geqlf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER.
 = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left,

	= 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . If <i>side</i> = 'L', $m \geq k \geq 0$; if <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psorm2l DOUBLE PRECISION for pdorm2l COMPLEX for pcunm2l COMPLEX*16 for pzunm2l. Pointer into the local memory to an array, DIMENSION(<i>lld_a</i> , <i>LOCc</i> (<i>ja+k-1</i>)). On entry, the <i>j</i> -th row must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqlf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', $\text{lld_a} \geq \max(1, \text{LOCr}(ia+m-1))$, if <i>side</i> = 'R', $\text{lld_a} \geq \max(1, \text{LOCr}(ia+n-1))$.
<i>ia</i>	(global) INTEGER.

	The row index in the global array <i>A</i> indicating the first row of <i>sub(A)</i> .
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of <i>sub(A)</i> .
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <i>psorm21</i> DOUBLE PRECISION for <i>pdorm21</i> COMPLEX for <i>pcunm21</i> COMPLEX*16 for <i>pzunm21</i> . Array, DIMENSION <i>LOCc(ja+n-1)</i> . This array contains the scalar factor <i>tau(j)</i> of the elementary reflector <i>H(j)</i> , as returned by <i>p?geqlf</i> . This array is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for <i>psorm21</i> DOUBLE PRECISION for <i>pdorm21</i> COMPLEX for <i>pcunm21</i> COMPLEX*16 for <i>pzunm21</i> . Pointer into the local memory to an array, DIMENSION (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>). On entry, the local pieces of the distributed matrix <i>sub(c)</i> .
<i>ic</i>	(global) INTEGER. The row index in the global array <i>c</i> indicating the first row of <i>sub(c)</i> .
<i>jc</i>	(global) INTEGER. The column index in the global array <i>c</i> indicating the first column of <i>sub(c)</i> .
<i>descc</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) REAL for <i>psorm21</i> DOUBLE PRECISION for <i>pdorm21</i> COMPLEX for <i>pcunm21</i>

lwork COMPLEX*16 for pzunm2l.
Workspace array, DIMENSION (*lwork*).
On exit, *work*(1) returns the minimal and optimal *lwork*.
(local or global) INTEGER.
The dimension of the array *work*.
lwork is local input and must be at least
if *side* = 'L', $lwork \geq mpc0 + \max(1, nqc0)$,
if *side* = 'R', $lwork \geq nqc0 + \max(\max(1, mpc0),$
 $\text{numroc}(\text{numroc}(n+icoffc, nb_a, 0, 0, npc0),$
 $nb_a, 0, 0, lcmq))$,
where
 $lcmq = lcm/npcol$,
 $lcm = iclm(nprow, npc0)$,
 $iroffc = \text{mod}(ic-1, mb_c)$,
 $icoffc = \text{mod}(jc-1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$,
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npc0)$,
 $Mqc0 = \text{numroc}(m+icoffc, nb_c, mycol, icrow,$
 $nprow)$,
 $Npc0 = \text{numroc}(n+iroffc, mb_c, myrow, iccol,$
 $npc0)$,
ilcm, *indxg2p*, and *numroc* are ScaLAPACK tool functions;
myrow, *mycol*, *nprow*, and *npcol* can be determined by
calling the subroutine *blacs_gridinfo*.
If *lwork* = -1, then *lwork* is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by *pxerbla*.

Output Parameters

c On exit, *c* is overwritten by $Q * \text{sub}(C)$, or $Q^T * \text{sub}(C) /$
 $Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
work On exit, *work*(1) returns the minimal and optimal *lwork*.
info (local) INTEGER.
= 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $info = - (i*100+j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, ($mb_a.eq.mb_c$.AND. $iroffa.eq.iroffc$.AND. $iarow.eq.icrow$)

If $side = 'R'$, ($mb_a.eq.nb_c$.AND. $iroffa.eq.iroffc$).

p?orm2r/p?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqrf (unblocked algorithm).

Syntax

```
call psorm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdorm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pcunm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine p?orm2r/p?unm2r overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

$Q*sub(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*sub(C) / Q^H*sub(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by [p?geqrf](#). Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

<i>side</i>	<p>(global) CHARACTER. = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.</p>
<i>trans</i>	<p>(global) CHARACTER. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)</p>
<i>m</i>	<p>(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.</p>
<i>n</i>	<p>(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.</p>
<i>k</i>	<p>(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. If $\text{side} = 'L'$, $m \geq k \geq 0$; if $\text{side} = 'R'$, $n \geq k \geq 0$.</p>
<i>a</i>	<p>(local) REAL for psorm2r DOUBLE PRECISION for pdorm2r COMPLEX for pcunm2r</p>

COMPLEX*16 for pzunm2r.
 Pointer into the local memory to an array,
 DIMENSION(*lld_a*, *LOCc*(*ja+k-1*)).
 On entry, the *j*-th column must contain the vector that
 defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$,
 as returned by `p?geqrf` in the *k* columns of its distributed
 matrix argument $A(ia:*, ja:ja+k-1)$. The argument
 $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored
 on exit.

If *side* = 'L', $lld_a \geq \max(1, LOCr(ia+m-1))$,
 if *side* = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$.

ia (global) INTEGER.
 The row index in the global array *A* indicating the first row
 of sub(*A*).

ja (global) INTEGER.
 The column index in the global array *A* indicating the first
 column of sub(*A*).

desca (global and local) INTEGER array of DIMENSION (*dlen_*).
 The array descriptor for the distributed matrix *A*.

tau (local)
 REAL for psorm2r
 DOUBLE PRECISION for pdorm2r
 COMPLEX for pcunm2r
 COMPLEX*16 for pzunm2r.
 Array, DIMENSION *LOCc*(*ja+k-1*). This array contains the
 scalar factors *tau*(*j*) of the elementary reflector $H(j)$, as
 returned by `p?geqrf`. This array is tied to the distributed
 matrix *A*.

c (local)
 REAL for psorm2r
 DOUBLE PRECISION for pdorm2r
 COMPLEX for pcunm2r
 COMPLEX*16 for pzunm2r.
 Pointer into the local memory to an array,
 DIMENSION(*lld_c*, *LOCc*(*jc+n-1*)).
 On entry, the local pieces of the distributed matrix sub (*c*).

ic (global) INTEGER.
The row index in the global array *c* indicating the first row of sub(*c*).

jc (global) INTEGER.
The column index in the global array *c* indicating the first column of sub(*c*).

descc (global and local) INTEGER array of DIMENSION (*dlen_*).
The array descriptor for the distributed matrix *c*.

work (local)
REAL for psorm2r
DOUBLE PRECISION for pdorm2r
COMPLEX for pcunm2r
COMPLEX*16 for pzunm2r.
Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
The dimension of the array *work*.
lwork is local input and must be at least
if *side* = 'L', $lwork \geq mpc0 + \max(1, nqc0)$,
if *side* = 'R', $lwork \geq nqc0 + \max(\max(1, mpc0),$
 $\text{numroc}(\text{numroc}(n+icoffc, nb_a, 0, 0, npcol),$
 $nb_a, 0, 0, lcmq)),$
where
 $lcmq = lcm/npcol,$
 $lcm = iclm(nprow, npcol),$
 $iroffc = \text{mod}(ic-1, mb_c),$
 $icoffc = \text{mod}(jc-1, nb_c),$
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol),$
 $Mqc0 = \text{numroc}(m+icoffc, nb_c, mycol, icrow,$
 $nprow),$
 $Npc0 = \text{numroc}(n+iroffc, mb_c, myrow, iccol,$
 $npcol),$
ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions;
myrow, *mycol*, *nprow*, and *npcol* can be determined by
calling the subroutine *blacs_gridinfo*.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by $Q * \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*mb_a*.eq.*mb_c* .AND. *iroffa*.eq.*iroffc* .AND. *iarow*.eq.*icrow*)

If *side* = 'R', (*mb_a*.eq.*nb_c* .AND. *iroffa*.eq.*iroffc*).

p?orml2/p?unml2

Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).

Syntax

```
call psorml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pdorml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pcunml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pzunml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine p?orml2/p?unml2 overwrites the general real/complex m -by- n distributed matrix sub (C)=C(ic:ic+m-1, jc:jc+n-1) with

$Q^T \text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ (for real flavors)

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ (for complex flavors)

as returned by p?gelqf . Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER.

= 'L': apply Q or Q^T for real flavors (Q^H for complex flavors)
 from the left,
 = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors)
 from the right.

trans (global) CHARACTER.
 = 'N': apply Q (no transpose)
 = 'T': apply Q^T (transpose, for real flavors)
 = 'C': apply Q^H (conjugate transpose, for complex flavors)

m (global) INTEGER.
 The number of rows to be operated on, that is, the number
 of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.

n (global) INTEGER.
 The number of columns to be operated on, that is, the
 number of columns of the distributed submatrix $\text{sub}(C)$. n
 ≥ 0 .

k (global) INTEGER.
 The number of elementary reflectors whose product defines
 the matrix Q .
 If $\text{side} = \text{'L'}$, $m \geq k \geq 0$;
 if $\text{side} = \text{'R'}$, $n \geq k \geq 0$.

a (local)
 REAL for psorml2
 DOUBLE PRECISION for pdorml2
 COMPLEX for pcunml2
 COMPLEX*16 for pzunml2.
 Pointer into the local memory to an array, DIMENSION
 (lld_a , $\text{LOCc}(ja+m-1)$ if $\text{side}=\text{'L'}$,
 (lld_a , $\text{LOCc}(ja+n-1)$ if $\text{side}=\text{'R'}$,
 where $\text{lld_a} \geq \max(1, \text{LOCr}(ia+k-1))$.
 On entry, the i -th row must contain the vector that defines
 the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as
 returned by [p?gelqf](#) in the k rows of its distributed matrix
 argument $A(ia:ia+k-1, ja:*)$. The argument
 $A(ia:ia+k-1, ja:*)$ is modified by the routine but
 restored on exit.

<i>ia</i>	<p>(global) INTEGER.</p> <p>The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).</p>
<i>ja</i>	<p>(global) INTEGER.</p> <p>The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array of DIMENSION (<i>dlen_</i>).</p> <p>The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for psorml2</p> <p>DOUBLE PRECISION for pdorml2</p> <p>COMPLEX for pcunml2</p> <p>COMPLEX*16 for pzunml2.</p> <p>Array, DIMENSION <i>LOCc(ia+k-1)</i>. This array contains the scalar factors <i>tau(i)</i> of the elementary reflector <i>H(i)</i>, as returned by p?gelqf. This array is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local)</p> <p>REAL for psorml2</p> <p>DOUBLE PRECISION for pdorml2</p> <p>COMPLEX for pcunml2</p> <p>COMPLEX*16 for pzunml2.</p> <p>Pointer into the local memory to an array, DIMENSION(<i>lld_c</i>, <i>LOCc(jc+n-1)</i>). On entry, the local pieces of the distributed matrix sub (<i>c</i>).</p>
<i>ic</i>	<p>(global) INTEGER.</p> <p>The row index in the global array <i>c</i> indicating the first row of sub(<i>c</i>).</p>
<i>jc</i>	<p>(global) INTEGER.</p> <p>The column index in the global array <i>c</i> indicating the first column of sub(<i>c</i>).</p>
<i>descc</i>	<p>(global and local) INTEGER array of DIMENSION (<i>dlen_</i>).</p> <p>The array descriptor for the distributed matrix <i>C</i>.</p>
<i>work</i>	<p>(local)</p> <p>REAL for psorml2</p> <p>DOUBLE PRECISION for pdorml2</p>

COMPLEX for pcunml2
 COMPLEX*16 for pzunml2.
 Workspace array, DIMENSION (*lwork*).
lwork (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least
 if *side* = 'L', $lwork \geq mqc0 + \max(\max(1, npc0),$
 $\text{numroc}(\text{numroc}(m+icoffc, mb_a, 0, 0, nprow),$
 $mb_a, 0, 0, lcm)),$
 if *side* = 'R', $lwork \geq npc0 + \max(1, mqc0),$
 where
 $lcmp = lcm / nprow,$
 $lcm = iclm(nprow, npc0),$
 $iroffc = \text{mod}(ic-1, mb_c),$
 $icoffc = \text{mod}(jc-1, nb_c),$
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npc0),$
 $Mpc0 = \text{numroc}(m+icoffc, mb_c, mycol, icrow,$
 $nprow),$
 $Nqc0 = \text{numroc}(n+iroffc, nb_c, myrow, iccol,$
 $npc0),$
 $ilcm, \text{indxg2p}$ and numroc are ScaLAPACK tool functions;
 $myrow, mycol, nprow,$ and $npc0$ can be determined by
 calling the subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by `pxerbla`.

Output Parameters

c On exit, *c* is overwritten by $Q^* \text{sub}(C)$, or $Q^T \text{sub}(C) /$
 $Q^H \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
work On exit, *work*(1) returns the minimal and optimal *lwork*.
info (local) INTEGER.
 = 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,
then $info = - (i*100+j)$,
if the i -th argument is a scalar and had an illegal value,
then $info = -i$.

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, $(nb_a.eq.mb_c .AND. icoffa.eq.iroffc)$

If $side = 'R'$, $(nb_a.eq.nb_c .AND. icoffa.eq.icroffc .AND. iacol.eq.iccol)$.

p?ormr2/p?unmr2

Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).

Syntax

```
call psormr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pcunmr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunmr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine p?ormr2/p?unmr2 overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^* \text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ (for real flavors)

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ (for complex flavors)

as returned by [p?gerqf](#). Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

side	(global) CHARACTER. = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
trans	(global) CHARACTER. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $\text{side} = 'L'$, $m \geq k \geq 0$; if $\text{side} = 'R'$, $n \geq k \geq 0$.
a	(local) REAL for psormr2

DOUBLE PRECISION for pdormr2
 COMPLEX for pcunmr2
 COMPLEX*16 for pzunmr2.

Pointer into the local memory to an array, DIMENSION

(lld_a, LOCc(ja+m-1) if side='L',
 (lld_a, LOCc(ja+n-1) if side='R',

where $lld_a \geq \max(1, LOCr(ia+k-1))$.

On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gerqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

The argument $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

ia

(global) INTEGER.

The row index in the global array A indicating the first row of sub(A).

ja

(global) INTEGER.

The column index in the global array A indicating the first column of sub(A).

desca

(global and local) INTEGER array of DIMENSION ($dlen_$).

The array descriptor for the distributed matrix A .

tau

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Array, DIMENSION $LOCc(ia+k-1)$. This array contains the scalar factors $tau(i)$ of the elementary reflector $H(i)$, as returned by [p?gerqf](#). This array is tied to the distributed matrix A .

c

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Pointer into the local memory to an array,
 DIMENSION(*lld_c*, *LOCc(jc+n-1)*). On entry, the local
 pieces of the distributed matrix sub (*c*).

ic (global) INTEGER.
 The row index in the global array *c* indicating the first row
 of sub(*c*).

jc (global) INTEGER.
 The column index in the global array *c* indicating the first
 column of sub(*c*).

descc (global and local) INTEGER array of DIMENSION (*dlen_*).
 The array descriptor for the distributed matrix *c*.

work (local)
 REAL for psormr2
 DOUBLE PRECISION for pdormr2
 COMPLEX for pcunmr2
 COMPLEX*16 for pzunmr2.
 Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least

```

if side = 'L', lwork ≥ mpc0 + max(max(1, nqc0),
numroc(numroc(m+iroffc, mb_a, 0, 0, nprow),
mb_a, 0, 0, lcmp)),
if side = 'R', lwork ≥ nqc0 + max(1, mpc0),
where lcmp = lcm/nprow,
lcm = iclm(nprow, npc0),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npc0),
Mpc0 = numroc(m+iroffc, mb_c, myrow, icrow,
nprow),
Nqc0 = numroc(n+icoffc, nb_c, mycol, iccol,
npc0),

```

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	On exit, <code>c</code> is overwritten by $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$
<code>work</code>	On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = - (i*100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If `side = 'L'`, (`nb_a.eq.mb_c .AND. icoffa.eq.iroffc`)

If `side = 'R'`, (`nb_a.eq.nb_c .AND. icoffa.eq.icoffc .AND. iacol.eq.iccol`).

p?pbtrsv

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.

Syntax

```
call pspbtrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

```
call pdpbtrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

```
call pcpbtrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

```
call pzpbttrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine p?pbtrsv solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Cholesky factorization code p?pbtrf and is stored in $A(1:n, ja:ja+n-1)$ and *af*. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*.

Routine p?pbtrf must be called first.

Input Parameters

uplo (global) CHARACTER. Must be 'U' or 'L'.
If *uplo* = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;

	<p>If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.</p>
<i>trans</i>	<p>(global) CHARACTER. Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <i>trans</i> = 'T' or 'C' for real flavors, solve with $A(1:n, ja:ja+n-1)^T$. If <i>trans</i> = 'C' for complex flavors, solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.</p>
<i>n</i>	<p>(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.</p>
<i>bw</i>	<p>(global) INTEGER. The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$.</p>
<i>nrhs</i>	<p>(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.</p>
<i>a</i>	<p>(local) REAL for pspbtrsv DOUBLE PRECISION for pdpbtrsv COMPLEX for pcgbtrsv COMPLEX*16 for pzpbtrsv. Pointer into the local memory to an array with the first DIMENSION $lld_a \geq (bw+1)$, stored in <i>desca</i>. On entry, this array contains the local pieces of the n-by-n symmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).</p>

<i>desca</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p> <p>If 1D type (<i>dtype_a</i> = 501), then <i>dlen</i> ≥ 7;</p> <p>If 2D type (<i>dtype_a</i> = 1), then <i>dlen</i> ≥ 9.</p> <p>Contains information on mapping of <i>A</i> to memory. (See ScaLAPACK manual for full description and options.)</p>
<i>b</i>	<p>(local)</p> <p>REAL for pspbtrsv DOUBLE PRECISION for pdpbtrsv COMPLEX for pcpbtrsv COMPLEX*16 for pzpbttrsv.</p> <p>Pointer into the local memory to an array of local lead</p> <p>DIMENSION <i>lld_b</i> ≥ <i>nb</i>.</p> <p>On entry, this array contains the local pieces of the right hand sides <i>B</i>(<i>jb:jb+n-1</i>, 1:<i>nrhs</i>).</p>
<i>ib</i>	<p>(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).</p>
<i>descb</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i>.</p> <p>If 1D type (<i>dtype_b</i> = 502), then <i>dlen</i> ≥ 7;</p> <p>If 2D type (<i>dtype_b</i> = 1), then <i>dlen</i> ≥ 9.</p> <p>Contains information on mapping of <i>B</i> to memory. Please, see ScaLAPACK manual for full description and options.</p>
<i>laf</i>	<p>(local)</p> <p>INTEGER. The size of user-input auxiliary Fillin space <i>af</i>.</p> <p>Must be <i>laf</i> ≥ (<i>nb</i>+2*<i>bw</i>)*<i>bw</i>. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).</p>
<i>work</i>	<p>(local)</p> <p>REAL for pspbtrsv DOUBLE PRECISION for pdpbtrsv COMPLEX for pcpbtrsv COMPLEX*16 for pzpbttrsv.</p>

The array *work* is a temporary workspace array of DIMENSION *lwork*. This space may be overwritten in between calls to routines.

lwork (local or global) INTEGER. The size of the user-input workspace *work*, must be at least $lwork \geq bw*nrhs$. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

af (local)
 REAL for pspbtrsv
 DOUBLE PRECISION for pdpbtrsv
 COMPLEX for pcpbtrsv
 COMPLEX*16 for pzpbttrsv.
 The array *af* is of DIMENSION *laf*. It contains auxiliary Fillin space. Fillin is created during the factorization routine [p?pbtrf](#) and this is stored in *af*. If a linear system is to be solved using [p?pbtrs](#) after the factorization routine, *af* must not be altered after the factorization.

b On exit, this array contains the local piece of the solutions distributed matrix *x*.

work(1) On exit, *work*(1) contains the minimum value of *lwork*.

info (local) INTEGER.
 = 0: successful exit
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
 then $info = -(i*100+j)$,
 if the *i*-th argument is a scalar and had an illegal value,
 then $info = -i$.

Application Notes

If the factorization routine and the solve routine are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space *af* must not be altered between calls to the factorization routine and the solve routine.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case $N/P \gg bw$ are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix A one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into P pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

- 1. Local Phase:** The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space af . Mathematically, this is equivalent to reordering the matrix A as PAP^T and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of A in memory.
- 2. Reduced System Phase:** A small $(bw * (P-1))$ system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space af . A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
- 3. Back Substitution Phase:** For a linear system, a local backsubstitution is performed on each processor in parallel.

p?pttrsv

*Solves a single triangular linear system via
frontsolve or backsolve where the triangular matrix
is a factor of a tridiagonal matrix computed by
p?pttrf.*

Syntax

```
call pspttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pdpttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pcpttrsv(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzpttrsv(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a tridiagonal triangular matrix factor produced by the Cholesky factorization code `p?pttrf` and is stored in $A(1:n, ja:ja+n-1)$ and `af`. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`.

Routine `p?pttrf` must be called first.

Input Parameters

`uplo` (global) CHARACTER. Must be 'U' or 'L'.
If `uplo` = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;

	<p>If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.</p>
<i>trans</i>	<p>(global) CHARACTER. Must be 'N' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <i>trans</i> = 'C' (for complex flavors), solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.</p>
<i>n</i>	<p>(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.</p>
<i>nrhs</i>	<p>(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.</p>
<i>d</i>	<p>(local) REAL for pspttrsv DOUBLE PRECISION for pdpttrsv COMPLEX for pcpttrsv COMPLEX*16 for pzpttrsv. Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq \text{desca}(nb_)$.</p>
<i>e</i>	<p>(local) REAL for pspttrsv DOUBLE PRECISION for pdpttrsv COMPLEX for pcpttrsv COMPLEX*16 for pzpttrsv. Pointer to the local part of the global vector storing the upper diagonal of the matrix; must be of size $\geq \text{desca}(nb_)$. Globally, $du(n)$ is not referenced, and <i>du</i> must be aligned with <i>d</i>.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p>

	<p>If 1D type (<i>dtype_a</i> = 501 or 502), then <i>dlen</i> ≥ 7;</p> <p>If 2D type (<i>dtype_a</i> = 1), then <i>dlen</i> ≥ 9.</p> <p>Contains information on mapping of <i>A</i> to memory. See ScaLAPACK manual for full description and options.</p>
<i>b</i>	<p>(local)</p> <p>REAL for pspttrsv DOUBLE PRECISION for pdpttrsv COMPLEX for pcpttrsv COMPLEX*16 for pzpttrsv.</p> <p>Pointer into the local memory to an array of local lead</p> <p>DIMENSION <i>lld_b</i> ≥ <i>nb</i>.</p> <p>On entry, this array contains the local pieces of the right hand sides <i>B</i>(<i>jb:jb+n-1</i>, 1:<i>nrhs</i>).</p>
<i>ib</i>	<p>(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).</p>
<i>descb</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i>.</p> <p>If 1D type (<i>dtype_b</i> = 502), then <i>dlen</i> ≥ 7;</p> <p>If 2D type (<i>dtype_b</i> = 1), then <i>dlen</i> ≥ 9.</p> <p>Contains information on mapping of <i>B</i> to memory. See ScaLAPACK manual for full description and options.</p>
<i>laf</i>	<p>(local)</p> <p>INTEGER. The size of user-input auxiliary Fillin space <i>af</i>.</p> <p>Must be <i>laf</i> ≥ (<i>nb</i>+2*<i>bw</i>)*<i>bw</i>.</p> <p>If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).</p>
<i>work</i>	<p>(local)</p> <p>REAL for pspttrsv DOUBLE PRECISION for pdpttrsv COMPLEX for pcpttrsv COMPLEX*16 for pzpttrsv.</p> <p>The array <i>work</i> is a temporary workspace array of DIMENSION <i>lwork</i>. This space may be overwritten in between calls to routines.</p>

lwork (local or global) INTEGER. The size of the user-input workspace *work*, must be at least $lwork \geq (10+2*\min(100, nrhs)) * npcol + 4*nrhs$. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

d, e (local).
 REAL for pspttrsv
 DOUBLE PRECISION for pdpttrsv
 COMPLEX for pcpttrsv
 COMPLEX*16 for pzpttrsv.
 On exit, these arrays contain information on the factors of the matrix.

af (local)
 REAL for pspttrsv
 DOUBLE PRECISION for pdpttrsv
 COMPLEX for pcpttrsv
 COMPLEX*16 for pzpttrsv.
 The array *af* is of DIMENSION *laf*. It contains auxiliary Fillin space. Fillin is created during the factorization routine [p?pbtrf](#) and this is stored in *af*. If a linear system is to be solved using [p?pttrs](#) after the factorization routine, *af* must not be altered after the factorization.

b On exit, this array contains the local piece of the solutions distributed matrix *X*.

work(1) On exit, *work*(1) contains the minimum value of *lwork*.

info (local) INTEGER.
 = 0: successful exit
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
 then *info* = $-(i*100+j)$,
 if the *i*-th argument is a scalar and had an illegal value,
 then *info* = $-i$.

p?potf2

Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).

Syntax

```
call pspotf2(uplo, n, a, ia, ja, desca, info)
call pdpotf2(uplo, n, a, ia, ja, desca, info)
call pcpotf2(uplo, n, a, ia, ja, desca, info)
call pzpotf2(uplo, n, a, ia, ja, desca, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

The factorization has the form

$\text{sub}(A) = U' * U$, if $uplo = 'U'$, or $\text{sub}(A) = L * L'$, if $uplo = 'L'$,

where U is an upper triangular matrix, L is lower triangular. X' denotes transpose (conjugate transpose) of X .

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored. = 'U': upper triangle of $\text{sub}(A)$ is stored; = 'L': lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>a</i>	(local) REAL for pspotf2 DOUBLE PRECISION or pdpotf2 COMPLEX for pcpotf2

COMPLEX*16 for pzpotf2.

Pointer into the local memory to an array of

`DIMENSION(11d_a, LOcc(ja+n-1))` containing the local pieces of the n -by- n symmetric distributed matrix `sub(A)` to be factored.

If `uplo = 'U'`, the leading n -by- n upper triangular part of `sub(A)` contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced.

If `uplo = 'L'`, the leading n -by- n lower triangular part of `sub(A)` contains the lower triangular matrix and the strictly upper triangular part of `sub(A)` is not referenced.

`ia, ja`

(global) INTEGER.

The row and column indices in the global array `A` indicating the first row and the first column of the `sub(A)`, respectively.

`desca`

(global and local) INTEGER array, `DIMENSION(dlen_)`. The array descriptor for the distributed matrix `A`.

Output Parameters

`a`

(local)

On exit,

if `uplo = 'U'`, the upper triangular part of the distributed matrix contains the Cholesky factor `U`;

if `uplo = 'L'`, the lower triangular part of the distributed matrix contains the Cholesky factor `L`.

`info`

(local) INTEGER.

= 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,

then `info = -(i*100+j)`,

if the i -th argument is a scalar and had an illegal value, then `info = -i`.

> 0: if `info = k`, the leading minor of order k is not positive definite, and the factorization could not be completed.

p?rscl

Multiplies a vector by the reciprocal of a real scalar.

Syntax

```
call psrscl(n, sa, sx, ix, jx, descx, incx)
call pdrsc1(n, sa, sx, ix, jx, descx, incx)
call pcsrscl(n, sa, sx, ix, jx, descx, incx)
call pzdrsc1(n, sa, sx, ix, jx, descx, incx)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine multiplies an n -element real/complex vector `sub(x)` by the real scalar $1/a$. This is done without overflow or underflow as long as the final result `sub(x)/a` does not overflow or underflow.

`sub(x)` denotes `x(ix:ix+n-1, jx:jx)`, if `incx = 1`,
and `x(ix:ix, jx:jx+n-1)`, if `incx = m_x`.

Input Parameters

<code>n</code>	(global) INTEGER. The number of components of the distributed vector <code>sub(x)</code> . $n \geq 0$.
<code>sa</code>	REAL for <code>psrscl/pcsrscl</code> DOUBLE PRECISION for <code>pdrsc1/pzdrsc1</code> . The scalar a that is used to divide each component of the vector x . This parameter must be ≥ 0 .
<code>sx</code>	REAL for <code>psrscl</code> DOUBLE PRECISION for <code>pdrsc1</code> COMPLEX for <code>pcsrscl</code> COMPLEX*16 for <code>pzdrsc1</code> . Array containing the local pieces of a distributed matrix of DIMENSION of at least $((jx-1)*m_x + ix + (n-1)*abs(incx))$. This array contains the entries of the distributed vector <code>sub(x)</code> .

<i>ix</i>	(global) INTEGER. The row index of the submatrix of the distributed matrix <i>x</i> to operate on.
<i>jx</i>	(global) INTEGER. The column index of the submatrix of the distributed matrix <i>x</i> to operate on.
<i>descx</i>	(global and local). INTEGER. Array of <code>DIMENSION 8</code> . The array descriptor for the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. The increment for the elements of <i>x</i> . This version supports only two values of <i>incx</i> , namely 1 and <i>m_x</i> .

Output Parameters

<i>sx</i>	On exit, the result x/a .
-----------	-----------------------------

p?sygs2/p?hegs2

Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).

Syntax

```
call pssygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pdsygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pchegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pzhegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
```

Description

The routine p?sygs2/p?hegs2 reduces a real symmetric-definite or a complex Hermitian-definite generalized eigenproblem to standard form.

Here $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$, and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and $\text{sub}(A)$ is overwritten by

$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ - for real flavors, and

$\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ - for complex flavors.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A) * \text{sub}(B) x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) x = \lambda * x$$

and $\text{sub}(A)$ is overwritten by

$U * \text{sub}(A) * U^T$ or $L * * T * \text{sub}(A) * L$ - for real flavors and

$U * \text{sub}(A) * U^H$ or $L * * H * \text{sub}(A) * L$ - for complex flavors.

The matrix $\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L * L^T$ (for real flavors), or as $U^H * U$ or $L * L^H$ (for complex flavors) by [p?potrf](#).

Input Parameters

ibtype (global) INTEGER.
 = 1:
 compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or
 $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ for real subroutines,
 and $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$
 for complex subroutines;
 = 2 or 3:
 compute $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$ for real subroutines,
 and $U * \text{sub}(A) * U^H$ or $L^H * \text{sub}(A) * L$ for complex subroutines.

uplo (global) CHARACTER
 Specifies whether the upper or lower triangular part of the
 symmetric/Hermitian matrix $\text{sub}(A)$ is stored, and how
 $\text{sub}(B)$ is factorized.
 = 'U': Upper triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is
 factorized as $U^T * U$ (for real subroutines) or as $U^H * U$ (for
 complex subroutines).
 = 'L': Lower triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is
 factorized as $L * L^T$ (for real subroutines) or as $L * L^H$ (for
 complex subroutines)

<i>n</i>	<p>(global) INTEGER.</p> <p>The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$. $n \geq 0$.</p>
<i>a</i>	<p>(local)</p> <p>REAL for pssygs2 DOUBLE PRECISION for pdsygs2 COMPLEX for pcheys2 COMPLEX*16 for pzhegs2.</p> <p>Pointer into the local memory to an array, <code>DIMENSION(lld_a, LOcc(ja+n-1))</code>.</p> <p>On entry, this array contains the local pieces of the n-by-n symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading n-by-n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.</p>
<i>ia, ja</i>	<p>(global) INTEGER.</p> <p>The row and column indices in the global array <i>A</i> indicating the first row and the first column of the $\text{sub}(A)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, <code>DIMENSION(dlen_)</code>. The array descriptor for the distributed matrix <i>A</i>.</p>
<i>B</i>	<p>(local)</p> <p>REAL for pssygs2 DOUBLE PRECISION for pdsygs2 COMPLEX for pcheys2 COMPLEX*16 for pzhegs2.</p> <p>Pointer into the local memory to an array, <code>DIMENSION(lld_b, LOcc(jb+n-1))</code>.</p> <p>On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by <code>p?potrf</code>.</p>
<i>ib, jb</i>	<p>(global) INTEGER.</p> <p>The row and column indices in the global array <i>B</i> indicating the first row and the first column of the $\text{sub}(B)$, respectively.</p>

descb (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *B*.

Output Parameters

a (local)
On exit, if *info* = 0, the transformed matrix is stored in the same format as sub(*A*).

info INTEGER.
= 0: successful exit.
< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
then *info* = - (*i**100),
if the *i*-th argument is a scalar and had an illegal value,
then *info* = -*i*.

p?sytd2/p?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).

Syntax

```
call pssytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pchetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Description

The routine p?sytd2/p?hetd2 reduces a real symmetric/complex Hermitian matrix sub(*A*) to symmetric/Hermitian tridiagonal form *T* by an orthogonal/unitary similarity transformation:

$Q' * \text{sub}(A) * Q = T$, where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

uplo (global) CHARACTER.

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored:
 = 'U': upper triangular
 = 'L': lower triangular

n (global) INTEGER.
 The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.

a (local)
 REAL for pssytd2
 DOUBLE PRECISION for pdsytd2
 COMPLEX for pchetd2
 COMPLEX*16 for pzhetd2.
 Pointer into the local memory to an array,
 DIMENSION(*lld_a*, LOC(*ja*+*n*-1)).
 On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$.
 If *uplo* = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.
 If *uplo* = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja (global) INTEGER.
 The row and column indices in the global array *A* indicating the first row and the first column of the $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *A*.

work (local)
 REAL for pssytd2
 DOUBLE PRECISION for pdsytd2
 COMPLEX for pchetd2
 COMPLEX*16 for pzhetd2.
 The array *work* is a temporary workspace array of
 DIMENSION *lwork*.

Output Parameters

<i>a</i>	<p>On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i>, and the elements above the first superdiagonal, with the array <i>tau</i>, represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors;</p> <p>if <i>uplo</i> = 'L', the diagonal and first subdiagonal of <i>A</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i>, and the elements below the first subdiagonal, with the array <i>tau</i>, represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors. See the <i>Application Notes</i> below.</p>
<i>d</i>	<p>(local)</p> <p>REAL for pssytd2/pchetd2</p> <p>DOUBLE PRECISION for pdsytd2/pzheta2.</p> <p>Array, DIMENSION(<i>LOCc</i>(<i>ja+n-1</i>)). The diagonal elements of the tridiagonal matrix <i>T</i>:</p> <p><i>d</i>(<i>i</i>) = <i>a</i>(<i>i</i>,<i>i</i>); <i>d</i> is tied to the distributed matrix <i>A</i>.</p>
<i>e</i>	<p>(local)</p> <p>REAL for pssytd2/pchetd2</p> <p>DOUBLE PRECISION for pdsytd2/pzheta2.</p> <p>Array, DIMENSION(<i>LOCc</i>(<i>ja+n-1</i>)),</p> <p>if <i>uplo</i> = 'U', <i>LOCc</i>(<i>ja+n-2</i>) otherwise.</p> <p>The off-diagonal elements of the tridiagonal matrix <i>T</i>:</p> <p><i>e</i>(<i>i</i>) = <i>a</i>(<i>i</i>,<i>i+1</i>) if <i>uplo</i> = 'U',</p> <p><i>e</i>(<i>i</i>) = <i>a</i>(<i>i+1</i>,<i>i</i>) if <i>uplo</i> = 'L'.</p> <p><i>e</i> is tied to the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for pssytd2</p> <p>DOUBLE PRECISION for pdsytd2</p> <p>COMPLEX for pchetd2</p> <p>COMPLEX*16 for pzheta2.</p> <p>Array, DIMENSION(<i>LOCc</i>(<i>ja+n-1</i>)).</p> <p>The scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>

<code>work(1)</code>	On exit, <code>work(1)</code> returns the minimal and optimal value of <code>lwork</code> .
<code>lwork</code>	(local or global) INTEGER. The dimension of the workspace array <code>work</code> . <code>lwork</code> is local input and must be at least $lwork \geq 3n$. If <code>lwork = -1</code> , then <code>lwork</code> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla .
<code>info</code>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = -(i*100)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

Application Notes

If `uplo = 'U'`, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $TAU(ja+i-1)$.

If `uplo = 'L'`, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $TAU(ja+i-1)$.

The contents of sub (*A*) on exit are illustrated by the following examples with $n = 5$:

$$\begin{array}{ll}
 \text{if } \text{uplo}='U': & \text{if } \text{uplo}='L': \\
 \begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{bmatrix} & \begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix}
 \end{array}$$

where d and e denotes diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

NOTE. The distributed submatrix $\text{sub}(A)$ must verify some alignment properties, namely the following expression should be true:

$(\text{mb_a.eq.nb_a} \text{ .AND. } \text{iroffa.eq.icoffa})$ with $\text{iroffa} = \text{mod}(\text{ia} - 1, \text{mb_a})$ and $\text{icoffa} = \text{mod}(\text{ja} - 1, \text{nb_a})$.

p?trti2

Computes the inverse of a triangular matrix (local unblocked algorithm).

Syntax

```
call pstrti2(uplo, diag, n, a, ia, ja, desca, info)
call pdtrti2(uplo, diag, n, a, ia, ja, desca, info)
call pctrti2(uplo, diag, n, a, ia, ja, desca, info)
call pztrti2(uplo, diag, n, a, ia, ja, desca, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes the inverse of a real/complex upper or lower triangular block matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+\text{n}-1, \text{ja}:\text{ja}+\text{n}-1)$.

This matrix should be contained in one and only one process memory space (local operation).

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the matrix sub (<i>A</i>) is upper or lower triangular. = 'U': sub (<i>A</i>) is upper triangular = 'L': sub (<i>A</i>) is lower triangular.</p>
<i>diag</i>	<p>(global) CHARACTER*1. Specifies whether or not the matrix <i>A</i> is unit triangular. = 'N': sub (<i>A</i>) is non-unit triangular = 'U': sub (<i>A</i>) is unit triangular.</p>
<i>n</i>	<p>(global) INTEGER. The number of rows and columns to be operated on, i.e., the order of the distributed submatrix sub (<i>A</i>). $n \geq 0$.</p>
<i>a</i>	<p>(local) REAL for pstrti2 DOUBLE PRECISION for pdtrti2 COMPLEX for pctrti2 COMPLEX*16 for pztrti2. Pointer into the local memory to an array, DIMENSION (<i>lld_a</i>, LOC(<i>ja</i>+<i>n</i>-1)). On entry, this array contains the local pieces of the triangular matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of the matrix sub(<i>A</i>) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(<i>A</i>) is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of the matrix sub(<i>A</i>) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(<i>A</i>) is not referenced. If <i>diag</i> = 'U', the diagonal elements of sub(<i>A</i>) are not referenced either and are assumed to be 1.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the sub(<i>A</i>), respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.</p>

Output Parameters

<i>a</i>	On exit, the (triangular) inverse of the original matrix, in the same storage format.
<i>info</i>	<p>INTEGER.</p> <p>= 0: successful exit</p> <p>< 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <i>info</i> = - (<i>i</i>*100), if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.</p>

?lamsh

Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.

Syntax

```
call slamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
call dlamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The subroutine should only be called when there are multiple shifts/bulges (*nbulge* > 1) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

Input Parameters

<i>s</i>	<p>(local)</p> <p>INTEGER, REAL for <code>slamsh</code></p> <p>DOUBLE PRECISION for <code>dlamsh</code></p> <p>Array, DIMENSION (<i>lds</i>,*).</p>
----------	-----------------------------------------------------------------------------------------------------------------------------------------------------

	On entry, the matrix of shifts. Only the 2x2 diagonal of s is referenced. It is assumed that s has $jblk$ double shifts (size 2).
lds	(local) INTEGER. On entry, the leading dimension of s ; unchanged on exit. $1 < nbulge \leq jblk \leq lds/2$.
$nbulge$	(local) INTEGER. On entry, the number of bulges to send through h (>1). $nbulge$ should be less than the maximum determined ($jblk$). $1 < nbulge \leq jblk \leq lds/2$.
$jblk$	(local) INTEGER. On entry, the leading dimension of s ; unchanged on exit.
h	(local) INTEGER. REAL for slamsh DOUBLE PRECISION for dlamsh Array, DIMENSION (lds, n). On entry, the local matrix to apply the shifts on. h should be aligned so that the starting row is 2.
ldh	(local) INTEGER. On entry, the leading dimension of H ; unchanged on exit.
n	(local) INTEGER. On entry, the size of H . If all the bulges are expected to go through, n should be at least $4nbulge+2$. Otherwise, $nbulge$ may be reduced by this routine.
ulp	(local) REAL for slamsh DOUBLE PRECISION for dlamsh On entry, machine precision. Unchanged on exit.

Output Parameters

s	On exit, the data is rearranged in the best order for applying.
$nbulge$	On exit, the maximum number of bulges that can be sent through.
h	On exit, the data is destroyed.

slaref

Applies Householder reflectors to matrices on either their rows or columns.

Syntax

```
call slaref(type, a, lda, wantz, z, ldz, block, irow1, icoll, istart, istop,
           itmp1, itmp2, lilo, lihiz, vecs, v2, v3, t1, t2, t3)
```

```
call dlaref(type, a, lda, wantz, z, ldz, block, irow1, icoll, istart, istop,
           itmp1, itmp2, lilo, lihiz, vecs, v2, v3, t1, t2, t3)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

<i>type</i>	(global) CHARACTER*1. If <i>type</i> = 'R', apply reflectors to the rows of the matrix (apply from left). Otherwise, apply reflectors to the columns of the matrix. Unchanged on exit.
<i>a</i>	(global) REAL for slaref DOUBLE PRECISION for dlaref Array, DIMENSION (<i>lda</i> , *). On entry, the matrix to receive the reflections.
<i>lda</i>	(local) INTEGER. On entry, the leading dimension of <i>a</i> ; unchanged on exit.
<i>wantz</i>	(global) LOGICAL. If <i>wantz</i> = .TRUE., apply any column reflections to <i>z</i> as well. If <i>wantz</i> = .FALSE., do no additional work on <i>z</i> .
<i>z</i>	(global) REAL for slaref DOUBLE PRECISION for dlaref Array, DIMENSION (<i>ldz</i> , *). On entry, the second matrix to receive column reflections.
<i>ldz</i>	(local) INTEGER.

	On entry, the leading dimension of z ; unchanged on exit.
<i>block</i>	(global). LOGICAL. = .TRUE. : apply several reflectors at once and read their data from the <i>vecs</i> array; = .FALSE. : apply the single reflector given by <i>v2</i> , <i>v3</i> , <i>t1</i> , <i>t2</i> , and <i>t3</i> .
<i>irow1</i>	(local) INTEGER. On entry, the local row element of the matrix A.
<i>icoll</i>	(local) INTEGER. On entry, the local column element of the matrix A.
<i>istart</i>	(global) INTEGER. Specifies the "number" of the first reflector. <i>istart</i> is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istart</i> is ignored if <i>block</i> is .FALSE. .
<i>istop</i>	(global) INTEGER. Specifies the "number" of the last reflector. <i>istop</i> is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istop</i> is ignored if <i>block</i> is .FALSE. .
<i>itmp1</i>	(local) INTEGER. Starting range into A. For rows, this is the local first column. For columns, this is the local first row.
<i>itmp2</i>	(local) INTEGER. Ending range into A. For rows, this is the local last column. For columns, this is the local last row.
<i>liloz, li hiz</i>	(local). INTEGER. Serve the same purpose as <i>itmp1</i> , <i>itmp2</i> but for z when <i>wantz</i> is set.
<i>vecs</i>	(global) REAL for slaref DOUBLE PRECISION for dlaref. Array of size $3 * n$ (matrix size). This array holds the size 3 reflectors one after another and is only accessed when <i>block</i> is .TRUE.
<i>v2,v3,t1,t2,t3</i>	(global). INTEGER. REAL for slaref DOUBLE PRECISION for dlaref.

These parameters hold information on a single size 3 Householder reflector and are read when *block* is `.FALSE.`, and overwritten when *block* is `.TRUE.`.

Output Parameters

<i>a</i>	On exit, the updated matrix.
<i>z</i>	Changed only if <i>wantz</i> is set. If <i>wantz</i> is <code>.FALSE.</code> , <i>z</i> is not referenced.
<i>irow1</i>	Undefined.
<i>icol1</i>	Undefined.
<i>v2,v3,t1,t2,t3</i>	These parameters are read when <i>block</i> is <code>.FALSE.</code> , and overwritten when <i>block</i> is <code>.TRUE.</code> .

?lasorte

Sorts eigenpairs by real and complex data types.

Syntax

```
call slasorte(s, lds, j, out, info)
call dlasorte(s, lds, j, out, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This routine does no parallel work and makes no calls.

Input Parameters

<i>s</i>	(local) INTEGER. REAL for <code>slasorte</code> DOUBLE PRECISION for <code>dlasorte</code> Array, DIMENSION (<i>lds</i>). On entry, a matrix already in Schur form.
<i>lds</i>	(local) INTEGER.

	On entry, the leading dimension of the array <i>s</i> ; unchanged on exit.
<i>j</i>	(local) INTEGER. On entry, the order of the matrix <i>s</i> ; unchanged on exit.
<i>out</i>	(local) INTEGER. REAL for <code>slasorte</code> DOUBLE PRECISION for <code>dlasorte</code> Array, DIMENSION (2* <i>j</i>). The work buffer required by the routine.
<i>info</i>	(local) INTEGER. Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix <i>s</i> was not originally in Schur form. 0 indicates successful completion.

Output Parameters

<i>s</i>	On exit, the diagonal blocks of <i>s</i> have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.
<i>out</i>	Work buffer.

?lasrt2

Sorts numbers in increasing or decreasing order.

Syntax

```
call slasrt2(id, n, d, key, info)
call dlasrt2(id, n, d, key, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine is modified LAPACK routine [?lasrt](#), which sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of `STACK` limits *n* to about 2^{32} .

Input Parameters

<i>id</i>	<p>CHARACTER*1. = 'I': sort <i>d</i> in increasing order; = 'D': sort <i>d</i> in decreasing order.</p>
<i>n</i>	INTEGER. The length of the array <i>d</i> .
<i>d</i>	<p>REAL for slasrt2 DOUBLE PRECISION for dlasrt2. Array, DIMENSION (<i>n</i>). On entry, the array to be sorted.</p>
<i>key</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>). On entry, <i>key</i> contains a key to each of the entries in <i>d</i>(). Typically, <i>key</i>(<i>i</i>) = <i>i</i> for all <i>i</i> .</p>

Output Parameters

<i>D</i>	<p>On exit, <i>d</i> has been sorted into increasing order ($d(1) \leq \dots \leq d(n)$) or into decreasing order ($d(1) \geq \dots \geq d(n)$), depending on <i>id</i>.</p>
<i>info</i>	<p>INTEGER. = 0: successful exit < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value.</p>
<i>key</i>	<p>On exit, <i>key</i> is permuted in exactly the same manner as <i>d</i>() was permuted from input to output. Therefore, if <i>key</i>(<i>i</i>) = <i>i</i> for all <i>i</i> upon input, then $d_{out}(i) = d_{in}(key(i))$.</p>

?stein2

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.

Syntax

```
call sstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail,
info)
```

```
call dstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail,
info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine is a modified LAPACK routine [?stein](#). It computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter `maxits` (currently set to 5).

Input Parameters

n	INTEGER. The order of the matrix T ($n \geq 0$).
m	INTEGER. The number of eigenvectors to be found ($0 \leq m \leq n$).
d, e, w	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.</p> <p>Arrays: $d(*)$, DIMENSION (n). The n diagonal elements of the tridiagonal matrix T. $e(*)$, DIMENSION (n). The $(n-1)$ subdiagonal elements of the tridiagonal matrix T, in elements 1 to $n-1$. $e(n)$ need not be set. $w(*)$, DIMENSION (n).</p>

The first m elements of w contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array w from `?stebz` with `ORDER = 'B'` is expected here).

The dimension of w must be at least $\max(1, n)$.

iblock

INTEGER.

Array, DIMENSION (n).

The submatrix indices associated with the corresponding eigenvalues in w ;

$iblock(i) = 1$, if eigenvalue $w(i)$ belongs to the first submatrix from the top,

$iblock(i) = 2$, if eigenvalue $w(i)$ belongs to the second submatrix, etc. (The output array *iblock* from `?stebz` is expected here).

isplit

INTEGER.

Array, DIMENSION (n).

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to $isplit(1)$, the second submatrix consists of rows/columns $isplit(1)+1$ through $isplit(2)$, etc. (The output array *isplit* from `?stebz` is expected here).

orfac

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

orfac specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within $orfac * ||T||$ of each other are to be orthogonalized.

ldz

INTEGER. The leading dimension of the output array z ; $ldz \geq \max(1, n)$.

work

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Workspace array, DIMENSION ($5n$).

iwork

INTEGER. Workspace array, DIMENSION (n).

Output Parameters

z

REAL for `sstein2`

DOUBLE PRECISION for `dstein2`
 Array, DIMENSION (`ldz`, `m`).
 The computed eigenvectors. The eigenvector associated with the eigenvalue $w(i)$ is stored in the i -th column of z . Any vector that fails to converge is set to its current iterate after `maxits` iterations.

`ifail` INTEGER.
 Array, DIMENSION (`m`).
 On normal exit, all elements of `ifail` are zero. If one or more eigenvectors fail to converge after `maxits` iterations, then their indices are stored in the array `ifail`.

`info` INTEGER.
`info` = 0, the exit is successful.
`info` < 0: if `info` = $-i$, the i -th had an illegal value.
`info` > 0: if `info` = i , then i eigenvectors failed to converge in `maxits` iterations. Their indices are stored in the array `ifail`.

?dbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Syntax

```
call sdbtf2(m, n, kl, ku, ab, ldab, info)
call ddbtf2(m, n, kl, ku, ab, ldab, info)
call cdbtf2(m, n, kl, ku, ab, ldab, info)
call zdbtf2(m, n, kl, ku, ab, ldab, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine computes an LU factorization of a general real/complex m -by- n band matrix A without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of A ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of A ($ku \geq 0$).
<i>ab</i>	REAL for sdbtf2 DOUBLE PRECISION for ddbtf2 COMPLEX for cdbtf2 COMPLEX*16 for zdbtf2. Array, DIMENSION (<i>ldab</i> , <i>n</i>). The matrix A in band storage, in rows $kl+1$ to $2kl+ku+1$; rows 1 to kl of the array need not be set. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: $ab(kl+ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . ($ldab \geq 2kl + ku + 1$)

Output Parameters

<i>ab</i>	On exit, details of the factorization: U is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$. See the <i>Application Notes</i> below for further details.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value, > 0: if <i>info</i> = + <i>i</i> , $u(i, i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

on entry	on exit
$\begin{bmatrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$	$\begin{bmatrix} * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{bmatrix}$

The routine does not use array elements marked *; elements marked + need not be set on entry, but the routine requires them to store elements of u , because of fill-in resulting from the row interchanges.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

```
call sdbtrf(m, n, kl, ku, ab, ldab, info)
call ddbtrf(m, n, kl, ku, ab, ldab, info)
call cdbtrf(m, n, kl, ku, ab, ldab, info)
call zdbtrf(m, n, kl, ku, ab, ldab, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine computes an LU factorization of a real m -by- n band matrix A without using partial pivoting or row interchanges.

This is the blocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of A ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of A ($ku \geq 0$).
<i>ab</i>	REAL for sdbtrf DOUBLE PRECISION for ddbtrf COMPLEX for cdbtrf COMPLEX*16 for zdbtrf. Array, DIMENSION (<i>ldab</i> , <i>n</i>). The matrix A in band storage, in rows $kl+1$ to $2kl+ku+1$; rows 1 to kl of the array need not be set. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: $ab(kl+ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . ($ldab \geq 2kl + ku + 1$)

Output Parameters

<i>ab</i>	On exit, details of the factorization: U is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$. See the <i>Application Notes</i> below for further details.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value, > 0: if <i>info</i> = + <i>i</i> , $u(i, i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

on entry	on exit
$\begin{bmatrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$	$\begin{bmatrix} * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{bmatrix}$

The routine does not use array elements marked *.

?dttrf

Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).

Syntax

```
call sdttrf(n, dl, d, du, info)
call ddttrf(n, dl, d, du, info)
call cdttrf(n, dl, d, du, info)
call zdttrf(n, dl, d, du, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine computes an LU factorization of a real or complex tridiagonal matrix A using elimination without partial pivoting.

The factorization has the form $A = L^*U$, where L is a product of unit lower bidiagonal matrices and U is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

n INTEGER. The order of the matrix A ($n \geq 0$).

dl, *d*, *du* REAL for sdttrf
 DOUBLE PRECISION for ddttrf
 COMPLEX for cdttrf
 COMPLEX*16 for zdttrf.
 Arrays containing elements of A .
 The array *dl* of DIMENSION ($n - 1$) contains the sub-diagonal elements of A .
 The array *d* of DIMENSION n contains the diagonal elements of A .
 The array *du* of DIMENSION ($n - 1$) contains the super-diagonal elements of A .

Output Parameters

dl Overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .

d Overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A .

du Overwritten by the $(n-1)$ elements of the first super-diagonal of U .

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-i$, the i -th argument had an illegal value,
 > 0: if *info* = i , $u(i, i)$ is exactly 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

?dttrsv

Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.

Syntax

```
call sdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call ddttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call cdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call zdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine solves one of the following systems of linear equations:

$$L * X = B, L^T * X = B, \text{ or } L^H * X = B,$$

$$U * X = B, U^T * X = B, \text{ or } U^H * X = B$$

with factors of the tridiagonal matrix A from the LU factorization computed by [?dttrf](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether to solve with L or U .
<i>trans</i>	CHARACTER. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $A * X = B$ is solved for X (no transpose). If <i>trans</i> = 'T', then $A^T * X = B$ is solved for X (transpose). If <i>trans</i> = 'C', then $A^H * X = B$ is solved for X (conjugate transpose).
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns in the matrix B ($nrhs \geq 0$).
<i>dl,d,du,b</i>	REAL for sdttrsv DOUBLE PRECISION for ddttrsv

COMPLEX for cdttrsv
COMPLEX*16 for zdttrsv.

Arrays of DIMENSIONS: $dl(n-1)$, $d(n)$, $du(n-1)$,
 $b(ldb, nrhs)$.

The array dl contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .

The array d contains n diagonal elements of the upper triangular matrix U from the LU factorization of A .

The array du contains the $(n-1)$ elements of the first super-diagonal of U .

On entry, the array b contains the right-hand side matrix B .

ldb

INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

Output Parameters

b

Overwritten by the solution matrix X .

$info$

INTEGER. If $info=0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

?pttrsv

*Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the $L^*D^*L^H$ factorization computed by ?pttrf.*

Syntax

```
call spttrsv(trans, n, nrhs, d, e, b, ldb, info)
call dpttrsv(trans, n, nrhs, d, e, b, ldb, info)
call cpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
call zpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine solves one of the triangular systems:

$L^T * X = B$, or $L * X = B$ for real flavors,

or

$L * X = B$, or $L^H * X = B$,

$U * X = B$, or $U^H * X = B$ for complex flavors,

where L (or U for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix A such that

$A = L * D * L^H$ (computed by `spttrf/dpttrf`)

or

$A = U^H * D * U$ or $A = L * D * L^H$ (computed by `cpttrf/zpttrf`).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:</p> <p>If <i>uplo</i> = 'U', e is the superdiagonal of U, and $A = U^H * D * U$ or $A = L * D * L^H$;</p> <p>if <i>uplo</i> = 'L', e is the subdiagonal of L, and $A = L * D * L^H$.</p> <p>The two forms are equivalent, if A is real.</p>
<i>trans</i>	<p>CHARACTER.</p> <p>Specifies the form of the system of equations:</p> <p>for real flavors:</p> <p>if <i>trans</i> = 'N': $L * X = B$ (no transpose)</p> <p>if <i>trans</i> = 'T': $L^T * X = B$ (transpose)</p> <p>for complex flavors:</p> <p>if <i>trans</i> = 'N': $U * X = B$ or $L * X = B$ (no transpose)</p> <p>if <i>trans</i> = 'C': $U^H * X = B$ or $L^H * X = B$ (conjugate transpose).</p>
<i>n</i>	<p>INTEGER. The order of the tridiagonal matrix A. $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right hand sides, that is, the number of columns of the matrix B. $nrhs \geq 0$.</p>

<i>d</i>	REAL array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> from the factorization computed by ?pttrf .
<i>e</i>	COMPLEX array, DIMENSION (<i>n</i> -1). The (<i>n</i> -1) off-diagonal elements of the unit bidiagonal factor <i>U</i> or <i>L</i> from the factorization computed by ?pttrf . See <i>uplo</i> .
<i>b</i>	COMPLEX array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). On entry, the right hand side matrix <i>B</i> .
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> . $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	On exit, the solution matrix <i>x</i> .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value.

?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

```
call ssteqr2(compz, n, d, e, z, ldz, nr, work, info)
call dsteqr2(compz, n, d, e, z, ldz, nr, work, info)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine is a modified version of LAPACK routine [?steqr](#). The routine [?steqr2](#) computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. [?steqr2](#) is modified from [?steqr](#) to allow each ScaLAPACK process running [?steqr2](#) to perform updates on a distributed matrix *Q*. Proper usage of [?steqr2](#) can be gleaned from examination of ScaLAPACK routine [p?syev](#).

Input Parameters

<i>compz</i>	<p>CHARACTER*1. Must be 'N' or 'I'.</p> <p>If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix <i>T</i>. <i>z</i> must be initialized to the identity matrix by p?laset or ?laset prior to entering this subroutine.</p>
<i>n</i>	<p>INTEGER. The order of the matrix $T(n \geq 0)$.</p>
<i>d, e, work</i>	<p>REAL for single-precision flavors</p> <p>DOUBLE PRECISION for double-precision flavors.</p> <p>Arrays: <i>d</i> contains the diagonal elements of <i>T</i>. The dimension of <i>d</i> must be at least $\max(1, n)$.</p> <p><i>e</i> contains the $(n-1)$ subdiagonal elements of <i>T</i>. The dimension of <i>e</i> must be at least $\max(1, n-1)$.</p> <p><i>work</i> is a workspace array. The dimension of <i>work</i> is $\max(1, 2*n-2)$. If <i>compz</i> = 'N', then <i>work</i> is not referenced.</p>
<i>z</i>	<p>(local)</p> <p>REAL for <i>ssteqr2</i></p> <p>DOUBLE PRECISION for <i>dsteqr2</i></p> <p>Array, global DIMENSION (<i>n, n</i>), local DIMENSION (<i>ldz, nr</i>). If <i>compz</i> = 'V', then <i>z</i> contains the orthogonal matrix used in the reduction to tridiagonal form.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the array <i>z</i>. Constraints:</p> <p>$ldz \geq 1$,</p> <p>$ldz \geq \max(1, n)$, if eigenvectors are desired.</p>
<i>nr</i>	<p>INTEGER. $nr = \max(1, \text{numroc}(n, nb, \text{myprow}, 0, \text{nprocs}))$.</p> <p>If <i>compz</i> = 'N', then <i>nr</i> is not referenced.</p>

Output Parameters

<i>d</i>	<p>REAL array, DIMENSION (<i>n</i>), for <i>ssteqr2</i>.</p> <p>DOUBLE PRECISION array, DIMENSION (<i>n</i>), for <i>dsteqr2</i>.</p> <p>On exit, the eigenvalues in ascending order, if <i>info</i> = 0. See also <i>info</i>.</p>
----------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

e REAL array, DIMENSION (*n*-1), for ssteqr2.
DOUBLE PRECISION array, DIMENSION (*n*-1), for dsteqr2.
On exit, *e* has been destroyed.

z (local)
REAL for ssteqr2
DOUBLE PRECISION for dsteqr2
Array, global DIMENSION (*n*, *n*), local DIMENSION (*ldz*, *nr*).
On exit, if *info* = 0, then,
if *compz* = 'V', *z* contains the orthonormal eigenvectors
of the original symmetric matrix, and if *compz* = 'I', *z*
contains the orthonormal eigenvectors of the symmetric
tridiagonal matrix. If *compz* = 'N', then *z* is not referenced.

info INTEGER.
info = 0, the exit is successful.
info < 0: if *info* = -*i*, the *i*-th had an illegal value.
info > 0: the algorithm has failed to find all the
eigenvalues in a total of 30*n* iterations;
if *info* = *i*, then *i* elements of *e* have not converged to
zero; on exit, *d* and *e* contain the elements of a symmetric
tridiagonal matrix, which is orthogonally similar to the
original matrix.

Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

Table 7-2 ScaLAPACK Utility Functions and Routines

Routine Name	Data Types	Description
p?labad	s, d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
p?lachkieee	s, d	Performs a simple check for the features of the IEEE standard. (C interface function).
p?lamch	s, d	Determines machine parameters for floating-point arithmetic.

Routine Name	Data Types	Description
p?lasnbt	s, d	Computes the position of the sign bit of a floating-point number. (C interface function).
pxerbla		Error handling routine called by ScaLAPACK routines.

p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call pslabad(ictxt, small, large)
call pdlabad(ictxt, small, large)
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine takes as input the values computed by [p?lamch](#) for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by [p?lamch](#). This subroutine is needed because [p?lamch](#) does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this routine performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

ictxt (global) INTEGER.
The BLACS context handle in which the computation takes place.

small (local).
REAL PRECISION for [pslabad](#).
DOUBLE PRECISION for [pdlabad](#).
On entry, the underflow threshold as computed by [p?lamch](#).

large (local).
 REAL PRECISION for pslabad.
 DOUBLE PRECISION for pdlabad.
 On entry, the overflow threshold as computed by p?lamch.

Output Parameters

small (local).
 On exit, if $\log_{10}(large)$ is sufficiently large, the square root of *small*, otherwise unchanged.

large (local).
 On exit, if $\log_{10}(large)$ is sufficiently large, the square root of *large*, otherwise unchanged.

p?latchieee

Performs a simple check for the features of the IEEE standard. (C interface function).

Syntax

```
void pslatchieee(int *isiee, float *rmax, float *rmin);
void pdlatchieee(int *isiee, float *rmax, float *rmin);
```

Description

For C interface, this routine is declared in mkl_scalapack.h file.

The routine performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, p?latchieee may not return.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

rmax (local).
 REAL for pslatchieee
 DOUBLE PRECISION for pdlatchieee

rmin The overflow threshold (= ?lamch ('O')).
 (local).
 REAL for pslachkieee
 DOUBLE PRECISION for pdlachkieee
 The underflow threshold (= ?lamch ('U')).

Output Parameters

isieee (local). INTEGER.
 On exit, *isieee* = 1 implies that all the features of the
 IEEE standard that we rely on are implemented. On exit,
 isieee = 0 implies that some the features of the IEEE
 standard that we rely on are missing.

p?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

val = pslamch(*ictxt*, *cmach*)

val = pdlamch(*ictxt*, *cmach*)

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

The routine determines single precision machine parameters.

Input Parameters

ictxt (global). INTEGER. The BLACS context handle in which the
 computation takes place.

cmach (global) CHARACTER*1.
 Specifies the value to be returned by p?lamch:
 = 'E' or 'e', p?lamch := eps
 = 'S' or 's', p?lamch := sfmin
 = 'B' or 'b', p?lamch := base
 = 'P' or 'p', p?lamch := eps*base
 = 'N' or 'n', p?lamch := t

```

= 'R' or 'r', p?lamch := rnd
= 'M' or 'm', p?lamch := emin
= 'U' or 'u', p?lamch := rmin
= 'L' or 'l', p?lamch := emax
= 'O' or 'o', p?lamch := rmax,
where
eps = relative machine precision
sfmin = safe minimum, such that 1/sfmin does not overflow
base = base of the machine
prec = eps*base
t = number of (base) digits in the mantissa
rnd = 1.0 when rounding occurs in addition, 0.0 otherwise
emin = minimum exponent before (gradual) underflow
rmin = underflow threshold -  $\text{base}^{(\text{emin}-1)}$ 
emax = largest exponent before overflow
rmax = overflow threshold -  $(\text{base}^{\text{emax}}) * (1-\text{eps})$ 

```

Output Parameters

val Value returned by the routine.

p?lasnbt

Computes the position of the sign bit of a floating-point number. (C interface function).

Syntax

```
void pslasnbt(int *ieflag);
```

```
void pdlasnbt(int *ieflag);
```

Description

For C interface, this routine is declared in `mkl_scalapack.h` file.

The routine finds the position of the signbit of a single/double precision floating point number. This routine assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

Output Parameters

`ieflag` INTEGER.
 This flag indicates the position of the signbit of any single/double precision floating point number.
`ieflag = 0`, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.
`ieflag = 1` indicates that the signbit is the 32-nd bit for a single precision routine.
 In the case of a double precision routine:
`ieflag = 1` indicates that the signbit is the 32-nd bit (Big Endian).
`ieflag = 2` indicates that the signbit is the 64-th bit (Little Endian).

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
call pxerbla(ictxt, sname, info)
```

Description

For C interface, this routine is declared in `mk1_scalapack.h` file.

This routine is an error handler for the *ScaLAPACK* routines. It is called by a *ScaLAPACK* routine if an input parameter has an invalid value. A message is printed. Program execution is not terminated. For the *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and it is left to the user to determine how the program should proceed. However, in the specialized low-level *ScaLAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *info* on return from a ScaLAPACK routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Input Parameters

<i>ictxt</i>	(global) INTEGER The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>sname</i>	(global) CHARACTER*6 The name of the routine which called <code>pxerbla</code> .
<i>info</i>	(global) INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

Sparse Solver Routines

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparse solver software to solve real or complex, symmetric, structurally symmetric or non-symmetric, positive definite, indefinite or Hermitian sparse linear system of equations.

The terms and concepts required to understand the use of the Intel MKL sparse solver routines are discussed in the [Appendix A "Linear Solvers Basics"](#) [Appendix "Linear Solvers Basics"](#) . If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes the direct sparse solver [PARDISO*](#) and the alternative interface for the direct sparse solver referred to here as [DSS interface](#); [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI); and [two preconditioners](#) based on the incomplete LU factorization technique.

PARDISO* - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the PARDISO* solver. The interface is Fortran, but can be called from C programs by observing Fortran parameter passing and naming conventions used by the supported compilers and operating systems. A discussion of the algorithms used in the PARDISO* software and more information on the solver can be found at <http://www.pardiso-project.org>.

The current implementation of the PARDISO* solver additionally supports the out-of-core (OOC) version.

The PARDISO* package is a high-performance, robust, memory efficient and easy to use software for solving large sparse symmetric and unsymmetric linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [[Schenk00-2](#)]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [[Schenk00](#), [Schenk01](#), [Schenk02](#), [Schenk03](#)]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture and a speedup of up to seven using eight processors has been observed.

The PARDISO* solver supports a wide range of sparse matrix types (see [Figure 8-1](#) below) and computes the solution of real or complex, symmetric, structurally symmetric or unsymmetric, positive definite, indefinite or Hermitian sparse linear system of equations on shared-memory multiprocessing architectures.

Figure 8-1 Sparse Matrices That Can Be Solved with the PARDISO* Solver

You can find a code example that uses the PARDISO interface routine to solve systems of linear equations in [PARDISO Code Examples](#) section in the [Appendix C](#).

pardiso

Calculates the solution of a set of sparse linear equations with multiple right-hand sides.

Syntax

Fortran:

```
call pardiso (pt, maxfct, mnum, type, phase, n, a, ia, ja, perm, nrhs, iparm,  
msglvl, b, x, error)
```

C:

```
pardiso (pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
iparm, &msglvl, b, x, &error);
```

(An underscore may or may not be required after “pardiso” depending on the OS and compiler conventions for that OS).

Interface:

```
SUBROUTINE pardiso (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs,
iparm, msglvl, b, x, error)
```

```
INTEGER *4 pt (64)
```

```
INTEGER *4 maxfct, mnum, mtype, phase, n, nrhs, error, ia(*), ja(*), perm(*),
iparm(*)
```

```
REAL *8 a(*), b(n,nrhs), x(n,nrhs)
```

Note that the above interface is given for the 32-bit architectures. For 64-bit architectures, the argument `pt(64)` must be defined as `INTEGER*8` type.

Description

This routine is declared in `mkl_pardiso.f77` for FORTRAN 77 interface, in `mkl_pardiso.f90` for Fortran 90 interface, and in `mkl_pardiso.h` for C interface.

PARDISO calculates the solution of a set of sparse linear equations

$$A \cdot X = B$$

with multiple right-hand sides, using a parallel LU , LDL or LL^T factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ matrices. PARDISO performs the following analysis steps depending on the structure of the input matrix A .

Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (included with Intel MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite matrices, and an approximation of x is found by forward and backward substitution and iterative refinements.

The coefficient matrix is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block. One or two passes of iterative refinements may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinements is effective for highly indefinite symmetric systems. Furthermore the accuracy of this method is for a large set of matrices from different applications areas as accurate as a direct factorization method that uses complete sparse pivoting techniques [[Schenk04](#)].

Another possibility to improve the pivoting accuracy is to use symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. The methods are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of x is found by forward and backward substitution and iterative refinements.

Unsymmetric Matrices: The solver first computes a non-symmetric permutation P_{MPS} and scaling matrices D_x and D_c with the aim to place large entries on the diagonal that enhances reliability of the numerical factorization process [[Duff99](#)]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)_T$ followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_xAD_cP$$

with supernode pivoting matrices Q and R . When the factorization algorithm reaches a point where it cannot factorize the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [[Li99](#)]. The magnitude of the potential pivot is tested against a constant threshold of $\alpha = \epsilon * ||A2||_{inf}$, where ϵ is the machine precision, $A2 = P * P_{MPS} * D_x * A * D_c * P$, and $||A2||_{inf}$ is the infinity norm of the scaled and permuted matrix A . Any tiny pivots encountered during elimination are set to the sign $(l_{II}) * \epsilon * ||A2||_{inf}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Direct-Iterative Preconditioning for Unsymmetric Linear Systems. The solver also allows for a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most of applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but the same identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. PARDISO uses a numerical factorization $A = LU$ for the first system and applies the factors L and U for the next steps in a preconditioned Krylow-Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to unsymmetric matrices in PARDISO and the user can select the method using only one input parameter. For further details see the parameter description (*iparm(4)*, *iparm(20)*).

Separate Forward and Backward Substitution.

The solver execution step (see [parameter](#) *phase* =33 below) can be divided into two or three separate substitutions: forward, backward and diagonal (if possible). This separation can be explained on the examples of solving system with different matrix types.

Real symmetric positive definite matrix A (*mtype* = 2) is factorized by PARDISO as $A = L^*L^T$. In this case solution of the system $A^*x=b$ can be found as sequence of substitutions: $L^*y=b$ (forward substitution, *phase* =331) and $L^T*x=y$ (backward substitution, *phase* =333).

Real unsymmetric matrix A (*mtype* = 11) is factorized by PARDISO as $A = L^*U$. In this case solution of the system $A^*x=b$ can be found by the following sequence: $L^*y=b$ (forward substitution, *phase* =331) and $U^*x=y$ (backward substitution, *phase* =333).

Solving system with a real symmetric indefinite matrix A (*mtype* = -2) is slightly different from above cases. PARDISO factorizes this matrix as $A=LDL^T$, and solution of the system $A^*x=b$ can be calculated as the following sequence of substitutions: $L^*y=b$ (forward substitution, *phase* =331) s: $D^*v=y$ (diagonal substitution, *phase* =332) and, finally $L^T*x=v$ (backward substitution, *phase* =333). Diagonal substitution makes sense only for indefinite matrices (*mtype* = -2, -4, 6). For matrices of other types solution can be found as described in the first two examples.

NOTE. Number of refinement steps (*iparm(8)*) must be set to zero if solution is calculated step by step (*phase* = 331, 332, 333), otherwise PARDISO produces wrong result.

NOTE. Different pivoting (*iparm*(21)) produces different LDL^T factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch and Kaufman pivoting. Of course the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step (*phase*=33) regardless of the pivoting used.

The **sparse data storage** in PARDISO follows the scheme described in [Sparse Matrix Storage Format](#) section with *ja* standing for *columns*, *ia* for *rowIndex*, and *a* for *values*. The algorithms in PARDISO require column indices *ja* to be increasingly ordered per row and the presence of the diagonal element per row for any symmetric or structurally symmetric matrix. The unsymmetric matrices need no diagonal elements in the PARDISO solver.

PARDISO performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

When an input data structure is not accessed in a call, a `NULL` pointer or any valid address can be passed as a place holder for that argument.

Input Parameters

pt

INTEGER*4 for 32 -bit operating systems;
 INTEGER*8 for 64 -bit operating systems
 Array, DIMENSION (64)

On entry, solver internal data address pointer. These addresses are passed to the solver and all related internal memory management is organized through this pointer

NOTE. *pt* is an integer array with 64 entries. It is very important that the pointer is initialized with zero at the first call of PARDISO. After that first call you should never modify the pointer, as a serious memory leak can occur. The integer length should be 4-byte on 32-bit operating systems and 8-byte on 64-bit operating systems.

<i>maxfct</i>	<p>INTEGER</p> <p>Maximal number of factors with identical nonzero sparsity structure that the user would like to keep at the same time in memory. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data management of the solver. In most of the applications this value is equal to 1.</p> <p>PARDISO can process several matrices with identical matrix sparsity pattern and store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers <i>pt</i>.</p>																		
<i>mnum</i>	<p>INTEGER</p> <p>Actual matrix for the solution phase. With this scalar you can define the matrix that you would like to factorize. The value must be: $1 \leq mnum \leq maxfct$.</p> <p>In most applications this value is equal to 1.</p>																		
<i>mtype</i>	<p>INTEGER</p> <p>This scalar value defines the matrix type. The PARDISO solver supports the following matrices:</p> <table> <tr> <td>= 1</td><td>real and structurally symmetric matrix</td></tr> <tr> <td>= 2</td><td>real and symmetric positive definite matrix</td></tr> <tr> <td>= -2</td><td>real and symmetric indefinite matrix</td></tr> <tr> <td>= 3</td><td>complex and structurally symmetric matrix</td></tr> <tr> <td>= 4</td><td>complex and Hermitian positive definite matrix</td></tr> <tr> <td>= -4</td><td>complex and Hermitian indefinite matrix</td></tr> <tr> <td>= 6</td><td>complex and symmetric matrix</td></tr> <tr> <td>= 11</td><td>real and unsymmetric matrix</td></tr> <tr> <td>= 13</td><td>complex and unsymmetric matrix</td></tr> </table> <p>This parameter influences the pivoting method.</p>	= 1	real and structurally symmetric matrix	= 2	real and symmetric positive definite matrix	= -2	real and symmetric indefinite matrix	= 3	complex and structurally symmetric matrix	= 4	complex and Hermitian positive definite matrix	= -4	complex and Hermitian indefinite matrix	= 6	complex and symmetric matrix	= 11	real and unsymmetric matrix	= 13	complex and unsymmetric matrix
= 1	real and structurally symmetric matrix																		
= 2	real and symmetric positive definite matrix																		
= -2	real and symmetric indefinite matrix																		
= 3	complex and structurally symmetric matrix																		
= 4	complex and Hermitian positive definite matrix																		
= -4	complex and Hermitian indefinite matrix																		
= 6	complex and symmetric matrix																		
= 11	real and unsymmetric matrix																		
= 13	complex and unsymmetric matrix																		
<i>phase</i>	<p>INTEGER</p>																		

Controls the execution of the solver. Usually it is a two-digit integer ij ($10I + j$, $1 \leq I \leq 3$, $I \leq j \leq 3$ for normal execution modes). The I digit indicates the starting phase of execution, and j indicates the ending phase. PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including iterative refinements

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see [above](#)).

- Termination and Memory Release Phase ($phase \leq 0$)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

<i>phase</i>	Solver Execution Steps
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
331	like <i>phase</i> =33, but only forward substitution
332	like <i>phase</i> =33, but only diagonal substitution
333	like <i>phase</i> =33, but only backward substitution
0	Release internal memory for <i>L</i> and <i>U</i> matrix number <i>mnum</i>
-1	Release all internal memory for all matrices

n	<p>INTEGER</p> <p>Number of equations in the sparse linear systems of equations $A * X = B$. Constraint: $n > 0$.</p>
a	<p>REAL/COMPLEX</p> <p>Array. Contains the non-zero elements of the coefficient matrix A corresponding to the indices in ja. The size of a is the same as that of ja and the coefficient matrix can be either real or complex. The matrix must be stored in compressed sparse row format with increasing values of ja for each row. Refer to <i>values</i> array description in Sparse Matrix Storage Format for more details.</p>

NOTE. The non-zero elements of each row of the matrix A must be stored in increasing order. For symmetric or structural symmetric matrices, it is also important that the diagonal elements are available and stored in the matrix. If the matrix is symmetric, the array a is only accessed in the factorization phase, in the triangular solution and iterative refinement phase. Unsymmetric matrices are accessed in all phases of the solution process.

ia	<p>INTEGER</p> <p>Array, dimension $(n+1)$. For $i \leq n$, $ia(i)$ points to the first column index of row i in the array ja in compressed sparse row format. That is, $ia(i)$ gives the index of the element in array a that contains the first non-zero element from row i of A. The last element $ia(n+1)$ is taken to be equal to the number of non-zero elements in A, plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Format for more details. The array ia is also accessed in all phases of the solution process. Note that the row and columns numbers start from 1.</p>
ja	<p>INTEGER</p>

Array. $ja(*)$ contains column indices of the sparse matrix A stored in compressed sparse row format. The indices in each row must be sorted in increasing order. The array ja is also accessed in all phases of the solution process. For symmetric and structurally symmetric matrices it is assumed that zero diagonal elements are also stored in the list of non-zero elements in a and ja . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Sparse Matrix Storage Format](#).

perm

INTEGER

Array, dimension (n). Holds the permutation vector of size n . The array *perm* is defined as follows. Let A be the original matrix and $B = P \cdot A \cdot P^T$ be the permuted matrix. Row (column) i of A is the $perm(i)$ row (column) of B . The numbering of the array must start with 1 and must describe a permutation.

On entry, you can apply your own fill-in reducing ordering to the solver. The permutation vector *perm* is used by the solver if $iparm(5) = 1$. The second purpose of the array *perm* is to return the permutation vector calculated during fill-in reducing ordering stage of PARDISO to the user. The permutation vector is returned into the *perm* array if $iparm(5) = 2$.

nrhs

INTEGER

Number of right-hand sides that need to be solved for.

iparm

INTEGER

Array, dimension (64). This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver. If $iparm(1) = 0$, PARDISO fills $iparm(1)$, and $iparm(4)$ through $iparm(64)$ with default values and uses them. Note that there is no default value for $iparm(3)$ and the user should supply this value, whether $iparm(1)$ is 0 or 1. Individual components of the *iparm* array are described below (some of them are described in the [Output Parameters](#) section).

***iparm(1)* - use default values.**

If $iparm(1) = 0$, $iparm(2)$ and $iparm(4)$ through $iparm(64)$ are filled with default values, otherwise the user has to supply all values in $iparm$ from $iparm(2)$ to $iparm(64)$.

$iparm(2)$ - fill-in reducing ordering.

$iparm(2)$ controls the fill-in reducing ordering for the input matrix. If $iparm(2)$ is 0, the minimum degree algorithm is applied [Li99], if $iparm(2)$ is 2, the solver uses the nested dissection algorithm from the METIS package [Karypis98]. The default value of $iparm(2)$ is 2.

$iparm(3)$ - currently is not used.

CAUTION. User can control the parallel execution of the solver by explicitly setting `MKL_NUM_THREADS`. If less processors are available than specified, the execution may slow down instead of speeding up. If the variable `MKL_NUM_THREADS` is not defined, then the solver uses all available processors.

There is no default value for $iparm(3)$.

$iparm(4)$ - preconditioned CGS.

This parameter controls preconditioned CGS [Sonn89] for unsymmetric or structural symmetric matrices and Conjugate-Gradients for symmetric matrices. $iparm(4)$ has the form

$$iparm(4) = 10 * L + K$$

The K and L values have the meanings as follow.

Value of K	Description
0	The factorization is always computed as required by <i>phase</i> .
1	CGS iteration replaces the computation of <i>LU</i> . The preconditioner is <i>LU</i> that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.

Value of κ

Description

2

CG iteration for symmetric matrices replaces the computation of LU . The preconditioner is LU that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.

Value L :

The value L controls the stopping criterion of the Krylow-Subspace iteration:

$\text{eps}_{\text{CGS}} = 10^{-L}$ is used in the stopping criterion

$$||dx_i|| / ||dx_i|| < \text{eps}_{\text{CGS}}$$

with $||dx_i|| = ||\text{inv}(L*U)*r_i||$ and r_i is the residuum at iteration i of the preconditioned Krylow-Subspace iteration.

Strategy: A maximum number of 150 iterations is fixed by expecting that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residuum excursions are checked and can terminate the iteration process. If $\text{phase} = 23$, then the factorization for a given A is automatically recomputed in these cases where the Krylow-Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylow-Subspace iteration is returned. Using $\text{phase} = 33$ results in an error message ($\text{error} = 4$) if the stopping criteria for the Krylow-Subspace iteration can not be reached. More information on the failure can be obtained from $\text{iparm}(20)$.

The default is $\text{iparm}(4) = 0$, and other values are only recommended for an advanced user. $\text{iparm}(4)$ must be greater or equal to zero.

Examples:

$\text{iparm}(4)$

Description

31

LU -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for unsymmetric matrices

***iparm*(4) Description**

- 61 *LU*-preconditioned CGS iteration with a
stopping criterion of 1.0E-6 for
unsymmetric matrices
- 62 *LU*-preconditioned CGS iteration with a
stopping criterion of 1.0E-6 for
symmetric matrices

***iparm*(5) - user permutation.**

This parameter controls whether the user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another possible use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of PARDISO.

This option may be useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end $P^* A^* P^T$), or if the user wants to use the permutation vector more than once for equal or similar matrices. For definition of the permutation, see description of the *perm* parameter.

If *parm*(5)=0 (default value), then the array *perm* is not used by PARDISO;

if *parm*(5)=1, then the user supplied fill-in reducing permutation is used;

if *parm*(5)=2, then PARDISO returns the permutation vector into the array *perm*.

***iparm*(6) - write solution on *x*.**

If *iparm*(6) is 0 (which is the default), then the array *x* contains the solution and the value of *b* is not changed. If *iparm*(6) is 1, then the solver will store the solution on the right hand side *b*.

Note that the array *x* is always used. The default value of *iparm*(6) is 0.

***iparm*(8) - iterative refinement step.**

On entry to the solve and iterative refinement step, *iparm*(8) should be set to the maximum number of iterative refinement steps that the solver will perform. The solver will not perform more than the absolute value of

iparm(8) steps of iterative refinement and will stop the process if a satisfactory level of accuracy of the solution in terms of backward error has been achieved.

Note that if *iparm(8)* < 0, the accumulation of the residuum is using extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of *iparm(8)*=0) and the iteration number executed is reported on *iparm(7)*.

The solver will automatically perform two steps of iterative refinements when perturbed pivots have been obtained during the numerical factorization and *iparm(8)* was equal to zero.

The number of performed iterative refinement steps is reported on *iparm(8)*.

The default value for *iparm(8)* is 0.

iparm(9)

This parameter is reserved for future use. Its value must be set to 0.

iparm(10) - **pivoting perturbation.**

This parameter instructs PARDISO how to handle small pivots or zero pivots for unsymmetric matrices (*mttype* =11 or *mttype* =13) and symmetric matrices (*mttype* =-2, *mttype* =-4, or *mttype* =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factorize the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].

The magnitude of the potential pivot is tested against a constant threshold of

$$\alpha = \text{eps} * ||A2||_{\text{inf}},$$

where $\text{eps} = 10^{(-iparm(10))}$, $A2 = P * P_{\text{MPS}} * D_c * A * D_c * P$, and $||A2||_{\text{inf}}$ is the infinity norm of the scaled and permuted matrix *A*. Any tiny pivots encountered during elimination are set to the sign (*l_II*) * $\text{eps} * ||A2||_{\text{inf}}$ - this trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-iparm(10))}$.

The default value of `iparm(10)` is 13 and therefore `eps = 1.0E-13` for unsymmetric matrices (`mtype = 11` or `mtype = 13`).

The default value of `iparm(10)` is 8, and therefore `eps = 1.0E-8` for symmetric indefinite matrices (`mtype = -2`, `mtype = -4`, or `mtype = 6`).

`iparm(11)` - scaling vectors.

PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied only to unsymmetric matrices (`mtype = 11` or `mtype = 13`). The scaling can also be used for symmetric indefinite matrices (`mtype = -2`, `mtype = -4`, or `mtype = 6`) when the symmetric weighted matchings are applied (`iparm(13) = 1`).

Use `iparm(11) = 1` (scaling) and `iparm(13) = 1` (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (`phase=11`) you must provide the numerical values of the matrix `A` in case of scaling and symmetric weighted matching.

The default value of `iparm(11)` is 1 for unsymmetric matrices (`mtype = 11` or `mtype = 13`). The default value of `iparm(11)` is 0 for symmetric indefinite matrices (`mtype = -2`, `mtype = -4`, or `mtype = 6`).

`iparm(12)`

This parameter is reserved for future use. Its value must be set to 0.

`iparm(13)` - improved accuracy using (non-)symmetric weighted matchings.

PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to our factorization methods and can be seen as a complement to the alternative idea of using more complete pivoting techniques during the numerical factorization.

It is recommended to use `iparm(11)=1` (scalings) and `iparm(13)=1` (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. It is also very important to note that in the analysis phase (`phase =11`) you must provide the numerical values of the matrix `A` in the case of scalings and symmetric weighted matchings.

The default value of `iparm(13)` is 1 for unsymmetric matrices (`mtype =11` or `mtype =13`). The default value of `iparm(13)` is 0 for symmetric matrices (`mtype =-2`, `mtype =-4`, or `mtype =6`).

`iparm(18)`

The solver will report the numbers of non-zero elements on the factors if `iparm(18) < 0` on entry.

The default value of `iparm(18)` is -1.

`iparm(19)` - MFlops of factorization.

If `iparm(19) < 0` on entry, the solver will report MFlop (1.0E6) that are necessary to factor the matrix `A`. This will increase the reordering time.

The default value of `iparm(19)` is 0.

`iparm(21)` - pivoting for symmetric indefinite matrices.

`iparm(21)` controls the pivoting method for sparse symmetric indefinite matrices. If `iparm(21)` is 0, then 1x1 diagonal pivoting is used. If `iparm(21)` is 1, then 1x1 and 2x2 Bunch and Kaufman pivoting will be used in the factorization process. If `iparm(21)` is 2, a very robust preprocessing method based on symmetric weighted matchings and 1x1 and 2x2 Bunch and Kaufman pivoting will be used in the factorization process. The default value of `iparm(21)` is 1. Bunch and Kaufman pivoting is available for matrices: `mtype=-2`, `mtype=-4`, or `mtype=6`.

`iparm(27)` - matrix checker.

If `iparm(27)=0` (default value), the PARDISO doesn't check the sparse matrix representation.

If `iparm(27)=1`, then PARDISO check integer arrays `ia` and `ja`. In particular, PARDISO checks whether column indices are sorted in increasing order within each row.

`iparm(60)` - version of PARDISO.

iparm(60) controls what version of PARDISO - out-of-core (OOC) version or in-core version - is used. The OOC PARDISO can solve very large problems by holding the matrix factors in files on the disk. Because of that the amount of main memory required by OOC PARDISO is significantly reduced.

WARNING. The current OOC version does not use threading, thus both the parameter *iparm*(3) and the variable `MKL_NUM_THREADS` must be set to 1 when *iparm*(60) is equal to 1 or 2.

If *iparm*(60) is set to 0, then the in-core PARDISO is used. If *iparm*(60) is set to 2 - the OOC PARDISO is used. If *iparm*(60) is set to 1 - the in-core PARDISO is used if the total memory (in MBytes) needed for storing the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` (its default value is 2000), and OOC PARDISO is used otherwise. The default value of *iparm*(60) is 0.

Note that if *iparm*(60) is equal to 1 or 2, and the total peak memory needed for strong local arrays is more than `MKL_PARDISO_OOC_MAX_CORE_SIZE`, the program stops with error -9. In this case, increase of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is recommended. OOC parameters can be set in the configuration file. You can set the path to this file and its name via environmental variable `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`.

Path and name are as follows:

```
<MKL_PARDISO_OOC_CFG_PATH >/<
MKL_PARDISO_OOC_CFG_FILE_NAME> for Linux* OS, and
<MKL_PARDISO_OOC_CFG_PATH >\<
MKL_PARDISO_OOC_CFG_FILE_NAME> for Windows* OS.
By default, the name of the file is pardiso_ooc.cfg and
it is placed to the current directory.
```

All temporary data files can be deleted or stored when the calculations are completed in accordance with the value of the environmental variable `MKL_PARDISO_OOC_KEEP_FILE`. If it is set to 1 (default value) - all files are deleted, if it is set to 0 - all files are stored.

By default, the OOC PARDISO uses the current directory for storing data, and all work arrays associated with the matrix factors are stored in files named `ooc_temp` with different extensions. These default values can be changed by using the environmental variable `MKL_PARDISO_OOC_PATH`.

To set the environmental variables

`MKL_PARDISO_OOC_MAX_CORE_SIZE`,

`MKL_PARDISO_OOC_KEEP_FILE`, and

`MKL_PARDISO_OOC_PATH`, the configuration file should be created with the following lines:

```
MKL_PARDISO_OOC_PATH = <path>\ooc_file
```

```
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
```

```
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where `<path>` - the directory for storing data, `ooc_file` - file name without extension, `N` - memory size in MBytes, it is not recommended to set this value greater than the size of the available RAM (default value - 2000 MBytes).

WARNING. Maximum length of the path lines in the configuration files is 1000 characters.

Alternatively the environment variables can be set via command line:

```
export MKL_PARDISO_OOC_PATH = <path>/ooc_file
```

```
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
```

```
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

for Linux* OS, and

```
set MKL_PARDISO_OOC_PATH = <path>\ooc_file
```

```
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
```

```
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

for Windows* OS.

NOTE. The values specified in a command line have higher priorities - it means that if variable is changed in the configuration file and in the command line, OOC PARDISO uses only value defined in the command line. Setting OOC parameters via command line is recommended.

msglvl

INTEGER

Message level information. If *msglvl* = 0 then PARDISO generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

b

REAL/COMPLEX

Array, dimension (*n*,*nrhs*). On entry, contains the right hand side vector/matrix *B*. Note that *b* is only accessed in the solution phase.

Output Parameters

pt

This parameter contains internal address pointers.

iparm

On output, some *iparm* values will report useful information, for example, numbers of non-zero elements in the factors, and so on.

***iparm*(7) - number of performed iterative refinement steps.**

The number of iterative refinement steps that are actually performed during the solve step.

***iparm*(14) - number of perturbed pivots.**

After factorization, *iparm*(14) contains the number of perturbed pivots during the elimination process for *mtype* =11, *mtype* =13, *mtype* =-2, *mtype* =-4, or *mtype* =-6.

***iparm*(15) - peak memory symbolic factorization.**

The parameter *iparm*(15) provides the user with the total peak memory in KBytes that the solver needed during the analysis and symbolic factorization phase. This value is only computed in phase 1.

***iparm*(16) - permanent memory symbolic factorization.**

The parameter *iparm*(16) provides the user with the permanent memory in KBytes that the solver needed from the analysis and symbolic factorization phase in the factorization and solve phases. This value is only computed in phase 1.

***iparm*(17) - memory numerical factorization and solution.**

The parameter *iparm*(17) provides the user with the total double precision memory consumption (KBytes) of the solver for the factorization and solve phases. This value is only computed in phase 2.

Note that the total peak memory solver consumption is $\max(iparm(15), iparm(16) + iparm(17))$

***iparm*(18) - number of non-zero elements in factors.**

The solver will report the numbers of non-zero elements on the factors if *iparm*(18) < 0 on entry.

***iparm*(19) - MFlops of factorization.**

Number of operations in MFlop (1.0E6 operations) that are necessary to factor the matrix *A* are returned to the user if *iparm*(19) < 0 on entry.

***iparm*(20) - CG/CGS diagnostics.**

The value is used to give CG/CGS diagnostics (for example, the number of iterations and cause of failure):

If *iparm*(20) > 0, CGS succeeded, and the number of iterations executed are reported in *iparm*(20).

If *iparm*(20) < 0, iterations executed, but CG/CGS failed.

The error report details in *iparm*(20) are of the form:

iparm(20) = - *it_cgs**10 - *cgs_error*.

If *phase* = 23, then the factors *L*, *U* are recomputed for the matrix *A* and the error flag *error* = 0 in case of a successful factorization. If *phase* = 33, then *error* = -4 signals the failure.

Description of *cgs_error* is given in the table below:

<i>cgs_error</i>	Description
1	- fluctuations of the residuum are too large
2	- dx _{max_it_cgs} /2 too large (slow convergence)

cgs_error Description

- 3
- stopping criterion not reached at
max_it_cgs
- 4
- perturbed pivots caused iterative
refinement
- 5
- factorization is too fast for this matrix. It
is better to use the factorization method with
iparm(4)=0

iparm(22) - **inertia: number of positive eigenvalues.**
The parameter *iparm*(22) reports the number of positive eigenvalues for symmetric indefinite matrices.

iparm(23) - **inertia: number of negative eigenvalues.**
The parameter *iparm*(23) reports the number of negative eigenvalues for symmetric indefinite matrices.

iparm(24) to *iparm*(59)

These parameters are reserved for future use. Their values must be set to 0.

iparm(61) - the total peak memory in MBytes that the solver used during the analysis and symbolic factorization phases if the in-core PARDISO is used. *iparm*(61) is similar to *iparm*(15), but *iparm*(15) returns the value of the total peak memory if the OOC PARDISO is used.

iparm(62) - the total double precision memory consumption in MBytes that the solver used during the analysis and symbolic factorization phase in the factorization and solver phases if the in-core PARDISO is used. *iparm*(62) is similar to *iparm*(16), but *iparm*(16) returns the value of the memory consumption if the OOC PARDISO is used.

iparm(63) - the total double precision memory consumption in MBytes that the solver used for factorization and solution phases if the in-core PARDISO is used. Value of *iparm*(63) is similar to *iparm*(17), but *iparm*(17) returns the value of the memory consumption if the OOC PARDISO is used.

b

x

On output, the array is replaced with the solution if
iparm(6) = 1.
REAL/COMPLEX

error

Array, dimension $(n,nrhs)$. On output, contains solution if $iparm(6)=0$. Note that x is only accessed in the solution phase.

INTEGER

The error indicator according to the below table:

<i>error</i>	Information
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-4	zero pivot, numerical factorization or iterative refinement problem
-5	unclassified (internal) error
-6	preordering failed (matrix types 11, 13 only)
-7	diagonal matrix problem
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	problems with opening OOC temporary files
-11	read/write problems with the OOC data file

Direct Sparse Solver (DSS) Interface Routines

Intel MKL supports an alternative to the PARDISO* interface for the direct sparse solver referred to here as DSS interface. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and exploits the general scheme described in [Linear Solvers Basics](#) for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process and an auxiliary routine for passing character strings from Fortran routines to C routines.

The current implementation of the DSS interface additionally supports the out-of-core (OOC) version.

[Table 8-1](#) lists the names of the routines and describes their general use.

Table 8-1 DSS Interface Routines

Routine	Description
<code>dss_create</code>	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.
<code>dss_define_structure</code>	Informs the solver of the locations of the non-zero elements of the array.
<code>dss_reorder</code>	Based on the non-zero structure of the matrix, this routine computes a permutation vector to reduce fill-in during the factoring process.
<code>dss_factor_real,</code> <code>dss_factor_complex</code>	Computes the LU , LDT^T or LL^T factorization of a real or complex matrix.
<code>dss_solve_real,</code> <code>dss_solve_complex</code>	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
<code>dss_delete</code>	Deletes all data structures created during the solving process.
<code>dss_statistics</code>	Returns statistics about various phases of the solving process. Gathers the following statistics: time taken to do reordering, time taken to do factorization, problem solving duration, determinant of a matrix, inertia of a matrix, number of floating point operations taken during factorization, peak memory symbolic factorization, permanent memory symbolic factorization, and memory numerical factorization and solution. This routine can be invoked in any phase of the solving process after the “reorder” phase, but before the “delete” phase. Note that appropriate argument(s) must be supplied to this routine to match the phase in which it is invoked.
<code>mkl_cvt_to_null_terminated_str</code>	Passes character strings from Fortran routines to C routines.

To find a single solution vector for a single system of equations with a single right hand side, the Intel MKL DSS interface routines are invoked in the order in which they are listed in [Table 8-1](#) , with the exception of `dss_statistics`, which is invoked as described in the table.

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is necessary to invoke the Intel MKL sparse routines in an order other than listed in the table. The DSS interface provides such option. The solving process is conceptually divided into six phases, as shown in [Figure 8-2](#) , that indicates the typical order(s) in which the DSS interface routines can be invoked.

Figure 8-2 Typical order for invoking DSS interface routines

See code examples that uses the DSS interface routines to solve systems of linear equations in [Direct Sparse Solver Examples](#) section in the appendix C.

DSS Interface Description

As noted in [Memory Allocation and Handles](#) section, each DSS routine reads or writes an opaque data object called a handle. It is declared as being of type `MKL_DSS_HANDLE` in this documentation. You can refer to [Memory Allocation and Handles](#) to determine the correct method for declaring a handle argument.

All other types in this documentation refer to the common Fortran types, `INTEGER`, `REAL`, `COMPLEX`, `DOUBLE PRECISION`, and `DOUBLE COMPLEX`.

C and C++ programmers should refer to [Calling Direct Sparse Solver and Preconditioner Routines From C/C++](#) section for information on mapping Fortran types to C/C++ types.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see [Implementation Details](#)). The routines accept options for setting the message and termination levels as described in [Table 8-2](#) . Additionally, the routines accept the option `MKL_DSS_DEFAULTS` that establishes the documented default options for each DSS routine.

Table 8-2 Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
MKL_DSS_MSG_LVL_SUCCESS	MKL_DSS_TERM_LVL_SUCCESS
MKL_DSS_MSG_LVL_INFO	MKL_DSS_TERM_LVL_INFO
MKL_DSS_MSG_LVL_WARNING	MKL_DSS_TERM_LVL_WARNING
MKL_DSS_MSG_LVL_ERROR	MKL_DSS_TERM_LVL_ERROR
MKL_DSS_MSG_LVL_FATAL	MKL_DSS_TERM_LVL_FATAL

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

Users can specify multiple options for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
CALL dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL DSS routines do not make copies of the user input arrays.

WARNING. The contents of these arrays cannot be modified after they are passed to one of the solver routines.

dss_create

Initializes the solver.

Syntax

```
dss_create(handle, opt)
```

Description

This routine is declared in `mkl_dss.f77` for FORTRAN 77 interface, in `mkl_dss.f90` for Fortran 90 interface, and in `mkl_dss.h` for C interface.

The routine `dss_create` initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel MKL DSS routines must use the value of `handle` returned by the routine `dss_create`.

WARNING. Do not write the value of `handle` directly.

The default value of the parameter `opt` is

```
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.
```

This parameter can control number of refinement steps used on the solution stage by specifying the two following values:

`MKL_DSS_REFINEMENT_OFF` - maximum number of refinement steps is set to zero;
`MKL_DSS_REFINEMENT_ON` (default value) - maximum number of refinement steps is set to 2.

This parameter can contain additionally one of two possible values to launch the out-of-core version of DSS (OOC DSS): `MKL_DSS_OOC_VARIABLE` and `MKL_DSS_OOC_STRONG`.

`MKL_DSS_OOC_STRONG` - OOC DSS is used.

`MKL_DSS_OOC_VARIABLE` - OOC DSS uses the in-core kernels of PARDISO* if there is enough memory for storing work arrays associated with the matrix factors in the main memory. Specifically, if the memory needed for the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE`, then the OOC version of PARDISO* uses the in-core computations, otherwise it uses the OOC computations.

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of the main memory allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000

MBytes. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the [PARDISO Parameters](#) description above).

WARNING. Do not change the behavior of the OOC DSS after it is specified in the routine `dss_create`.

Input Parameters

opt INTEGER Options passing argument. The default value is `MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

Output Parameters

handle Data object of the `MKL_DSS_HANDLE` type (see [Interface Description](#)).

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OUT_OF_MEMORY`

dss_define_structure

Communicates locations of non-zero elements in the matrix to the solver.

Syntax

```
dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

Description

This routine is declared in `mkl_dss.f77` for FORTRAN 77 interface, in `mkl_dss.f90` for Fortran 90 interface, and in `mkl_dss.h` for C interface.

The routine `dss_define_structure` communicates the locations of the *nNonZeros* number of non-zero elements in a matrix of *nRows* by *nCols* size to the solver.

Note that currently the Intel MKL DSS software operates only on square matrices, so *nRows* must be equal to *nCols*.

To communicate the locations of non-zeros in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying one of the following values for the options argument *opt*:
 - MKL_DSS_SYMMETRIC_STRUCTURE
 - MKL_DSS_SYMMETRIC
 - MKL_DSS_NON_SYMMETRIC
2. Provide the actual locations of the non-zeros by means of the arrays *rowIndex* and *columns* (see [Sparse Matrix Storage Format](#)).

Input Parameters

<i>opt</i>	INTEGER. Options passing argument. The default option for the matrix structure is MKL_DSS_SYMMETRIC.
<i>rowIndex</i>	INTEGER. Array of size $\min(nRows, nCols)+1$. Defines the location of non-zero entries in the matrix.
<i>nRows</i>	INTEGER. Number of rows in the matrix.
<i>nCols</i>	INTEGER. Number of columns in the matrix.
<i>columns</i>	INTEGER. Array of size <i>nNonZeros</i> . Defines the location of non-zero entries in the matrix.
<i>nNonZeros</i>	INTEGER. Number of non-zero elements in the matrix.

WARNING. Pointers to the *rowIndex* and *columns* are stored in the handle. These arrays are used when the solver runs. Do not free or delete them before calling *dss_solve_real* or *dss_solver_complex*.

Output Parameters

<i>handle</i>	Data object of the MKL_DSS_HANDLE type (see Interface Description).
---------------	--------------------------------------------------------------------------------------

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_COL_ERR
 MKL_DSS_NOT_SQUARE
 MKL_DSS_TOO_FEW_VALUES
 MKL_DSS_TOO_MANY_VALUES

dss_reorder

Computes permutation vector that minimizes the fill-in during the factorization phase.

Syntax

`dss_reorder(handle, opt, perm)`

Description

This routine is declared in `mkl_dss.f77` for FORTRAN 77 interface, in `mkl_dss.f90` for Fortran 90 interface, and in `mkl_dss.h` for C interface.

If `opt` contains the option `MKL_DSS_AUTO_ORDER`, then the routine `dss_reorder` computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the `perm` array is never accessed.

If `opt` contains the option `MKL_DSS_MY_ORDER`, then the array `perm` is considered to be a permutation vector supplied by the user. In this case, the array `perm` is of length `nRows`, where `nRows` is the number of rows in the matrix as defined by the previous call to [dss_define_structure](#).

Input Parameters

<code>opt</code>	INTEGER. Option passing argument. The default option for the permutation type is <code>MKL_DSS_AUTO_ORDER</code> .
<code>perm</code>	INTEGER. Array of length <code>nRows</code> . Contains a user-defined permutation vector (accessed only if <code>opt</code> contains <code>MKL_DSS_MY_ORDER</code>).

Output Parameters

handle Data object of the MKL_DSS_HANDLE type (see [Interface Description](#)).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

dss_factor_real, dss_factor_complex

Compute factorization of the matrix with previously specified location.

Syntax

```
dss_factor_real(handle, opt, rValues)
```

```
dss_factor_complex(handle, opt, cValues)
```

Description

This routine is declared in `mkl_dss.f77` for FORTRAN 77 interface, in `mkl_dss.f90` for Fortran 90 interface, and in `mkl_dss.h` for C interface.

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to [dss_define_structure](#) and whose non-zero values are given in the array *rValues* or *cValues*. The arrays *rValues* and *cValues* are assumed to be of length *nNonZeros* as defined in a previous call to `dss_define_structure`.

The *opt* argument should contain one of the following options:

- MKL_DSS_POSITIVE_DEFINITE,
- MKL_DSS_INDEFINITE,
- MKL_DSS_HERMITIAN_POSITIVE_DEFINITE,
- MKL_DSS_HERMITIAN_INDEFINITE ,

depending on whether the non-zero values in *rValues* and *cValues* describe a positive definite, indefinite, or Hermitian matrix.

Input Parameters

<i>handle</i>	Data object of the MKL_DSS_HANDLE type (see Interface Description).
<i>opt</i>	INTEGER Options passing argument. The default option for the matrix type is MKL_DSS_POSITIVE_DEFINITE.
<i>rValues</i>	DOUBLE PRECISION. Array of size <i>nNonZeros</i> . Contains real non-zero elements of the matrix.
<i>cValues</i>	DOUBLE COMPLEX. Array of size <i>nNonZeros</i> . Contains complex non-zero elements of the matrix.

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_OPTION_CONFLICT
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_ZERO_PIVOT

dss_solve_real, dss_solve_complex

Compute the corresponding solutions vector and place it in the output array.

Syntax

```
dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)
dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Description

These routines are declared in `mk1_dss.f77` for FORTRAN 77 interface, in `mk1_dss.f90` for Fortran 90 interface, and in `mk1_dss.h` for C interface.

For each right hand side column vector defined in the arrays *rRhsValues* or *cRhsValues*, these routines compute the corresponding solutions vector and place it in the arrays *rSolValues* or *cSolValues*.

The lengths of the right-hand side and solution vectors, *nCols* and *nRows* respectively, are assumed to have been defined in a previous call to [dss_define_structure](#).

By default, both routines perform full solution step (it corresponds to *phase* =33 in PARDISO). The parameter *opt* allows to calculate the final solution step-by-step, calling forward and backward substitutions. If it is set to MKL_DSS_FORWARD_SOLVE - the forward substitution (corresponding to *phase* =331 in PARDISO) is performed, if it is set to MKL_DSS_DIAGONAL_SOLVE - the diagonal substitution (corresponding to *phase* =332 in PARDISO) is performed, and if it is set to MKL_DSS_BACKWARD_SOLVE - the backward substitution (corresponding to *phase* =333 in PARDISO) is performed. For more details about using these substitutions for different types of matrices, see [description of the PARDISO solver](#).

This parameter also can control number of refinement steps that is used on the solution stage: if it is set to MKL_DSS_REFINEMENT_OFF, the maximum number of refinement steps equal to zero, and if it is set to MKL_DSS_REFINEMENT_ON (default value), the maximum number of refinement steps is equal to 2.

Input Parameters

<i>handle</i>	Data object of the MKL_DSS_HANDLE type (see Interface Description).
<i>opt</i>	INTEGER. Options passing argument.
<i>nRhs</i>	INTEGER. Number of the right-hand sides in the linear equation.
<i>rRhsValues</i>	DOUBLE PRECISION. Array of size <i>nRows</i> by <i>nRhs</i> . Contains real right-hand side vectors.
<i>cRhsValues</i>	DOUBLE COMPLEX. Array of size <i>nRows</i> by <i>nRhs</i> . Contains complex right-hand side vectors.

Output Parameters

<i>rSolValues</i>	DOUBLE PRECISION. Array of size <i>nCols</i> by <i>nRhs</i> . Contains real solution vectors.
<i>cSolValues</i>	DOUBLE COMPLEX. Array of size <i>nCols</i> by <i>nRhs</i> . Contains complex solution vectors.

Return Values

MKL_DSS_SUCCESS
MKL_DSS_STATE_ERR
MKL_DSS_INVALID_OPTION
MKL_DSS_OUT_OF_MEMORY

dss_delete

Deletes all of data structures created during the solutions process.

Syntax

`dss_delete(handle, opt)`

Description

This routine is declared in `mk1_dss.f77` for FORTRAN 77 interface, in `mk1_dss.f90` for Fortran 90 interface, and in `mk1_dss.h` for C interface.

The routine `dss_delete` deletes all data structures created during the solving process.

Input Parameters

opt INTEGER. Options passing argument. The default value is
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.

Output Parameters

handle Data object of the MKL_DSS_HANDLE type (see [Interface Description](#)).

Return Values

MKL_DSS_SUCCESS
MKL_DSS_INVALID_OPTION
MKL_DSS_OUT_OF_MEMORY

dss_statistics

Returns statistics about various phases of the solving process.

Syntax

```
dss_statistics(handle, opt, statArr, retValues)
```

Description

This routine is declared in `mkl_dss.f77` for FORTRAN 77 interface, in `mkl_dss.f90` for Fortran 90 interface, and in `mkl_dss.h` for C interface.

The `dss_statistics` routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- problem solving duration,
- determinant of a matrix,
- inertia of a matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter `statArr`. The value of the statistics is returned in double precision in a return array allocated by user.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics must be requested only at the appropriate stages of the solving process. For example, inquiring about `FactorTime` before a matrix is factored leads to errors.

The following table shows the point at which each individual statistics item can be called:

Table 8-3 Statistics Calling Sequences

Type of Statistics	When to Call
ReorderTime	After <code>dss_reorder</code> is completed successfully.

Type of Statistics	When to Call
FactorTime	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
SolveTime	After <code>dss_solve_real</code> or <code>dss_solve_complex</code> is completed successfully.
Determinant	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
Inertia	After <code>dss_factor_real</code> is completed successfully and the matrix is real, symmetric, and indefinite.
Flops	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
Peakmem	After <code>dss_reorder</code> is completed successfully.
Factormem	After <code>dss_reorder</code> is completed successfully.
Solvemem	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.

Input Parameters

<i>handle</i>	Data object of the MKL_DSS_HANDLE type (see Interface Description).								
<i>opt</i>	INTEGER. Options passing argument.								
<i>statArr</i>	STRING. Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect): <table><tr><td>ReorderTime</td><td>Amount of time taken to do the reordering.</td></tr><tr><td>FactorTime</td><td>Amount of time taken to do the factorization.</td></tr><tr><td>SolveTime</td><td>Amount of time taken to solve the problem after factorization.</td></tr><tr><td>Determinant</td><td>Determinant of the matrix <i>A</i>. For real matrices: the determinant is returned as <i>det_pow</i>, <i>det_base</i> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_base}) < 10.0$ and $\text{determinant} = \text{det_base} * 10^{(\text{det_pow})}$. For complex matrices: the determinant is returned as <i>det_pow</i>, <i>det_re</i>, <i>det_im</i> in three consecutive return array</td></tr></table>	ReorderTime	Amount of time taken to do the reordering.	FactorTime	Amount of time taken to do the factorization.	SolveTime	Amount of time taken to solve the problem after factorization.	Determinant	Determinant of the matrix <i>A</i> . For real matrices: the determinant is returned as <i>det_pow</i> , <i>det_base</i> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_base}) < 10.0$ and $\text{determinant} = \text{det_base} * 10^{(\text{det_pow})}$. For complex matrices: the determinant is returned as <i>det_pow</i> , <i>det_re</i> , <i>det_im</i> in three consecutive return array
ReorderTime	Amount of time taken to do the reordering.								
FactorTime	Amount of time taken to do the factorization.								
SolveTime	Amount of time taken to solve the problem after factorization.								
Determinant	Determinant of the matrix <i>A</i> . For real matrices: the determinant is returned as <i>det_pow</i> , <i>det_base</i> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_base}) < 10.0$ and $\text{determinant} = \text{det_base} * 10^{(\text{det_pow})}$. For complex matrices: the determinant is returned as <i>det_pow</i> , <i>det_re</i> , <i>det_im</i> in three consecutive return array								

	locations, where $1.0 \leq \text{abs}(\text{det_re}) + \text{abs}(\text{det_im}) < 10.0$ and $\text{determinant} = \text{det_re} + \text{det_im} * 10^{(\text{det_pow})}$.
Inertia	<p>Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z), where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues.</p> <p><code>Inertia</code> is returned as three consecutive return array locations as p, n, z.</p> <p>Computing <code>Inertia</code> is recommended only for stable matrices. Unstable matrices can lead to incorrect results.</p> <p><code>Inertia</code> of a k-by-k real symmetric positive definite matrix is always $(k, 0, 0)$. Therefore <code>Inertia</code> is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.</p>
Flops	Number of floating point operations performed during the factorization.
Peakmem	Total peak memory in KBytes that the solver needs during the analysis and symbolic factorization phase.
Factormem	Permanent memory in KBytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.
Solvemem	Total double precision memory consumption (KBytes) of the solver for the factorization and solve phases.

NOTE. To avoid problems in passing strings from Fortran to C, Fortran users must call the `mkl_cvt_to_null_terminated_str` routine before calling `dss_statistics`. Refer to the description of [mkl_cvt_to_null_terminated_str](#) for details.

Output Parameters

retValues DOUBLE PRECISION. Value of the statistics returned.

Finding “time used to reorder” and “inertia” of a matrix.

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics(handle, opt, statArr, retValues)`, where *statArr* is “ReorderTime,Inertia”

In this example, *retValues* has the following values:

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATISTICS_INVALID_MATRIX
 MKL_DSS_STATISTICS_INVALID_STATE
 MKL_DSS_STATISTICS_INVALID_STRING

mkl_cvt_to_null_terminated_str

Passes character strings from Fortran routines to C routines.

Syntax

`mkl_cvt_to_null_terminated_str (destStr, destLen, srcStr)`

Description

This routine is declared in `mkl_dss.f77` for FORTRAN 77 interface and in `mkl_dss.f90` for Fortran 90 interface.

The routine `mkl_cvt_to_null_terminated_str` passes character strings from Fortran routines to C routines. The strings are converted into integer arrays before being passed to C. Using this routine avoids the problems that can occur on some platforms when passing strings from Fortran to C. The use of this routine is highly recommended.

Input Parameters

destLen INTEGER. Length of the output array *destStr*.

srcStr STRING. Input string.

Output Parameters

destStr INTEGER. One-dimensional array of integer.

Implementation Details

Several aspects of the Intel MKL DSS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, one of the following Intel MKL DSS language-specific header files can be included:

- `mk1_dss.f77` for F77 programs
- `mk1_dss.f90` for F90 programs
- `mk1_dss.h` for C programs

These header files define symbolic constants for error returns, function options, certain defined data types, and function prototypes.

NOTE. Constants for options, error returns, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel MKL DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

To simplify the use of the Intel MKL DSS routines, they do not require the user to allocate any temporary working storage. The solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using an opaque data object called a *handle*.

Each of the Intel MKL DSS routines creates, uses or deletes a handle. Consequently, user programs must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that should be used when declaring a handle object in the user code.

Fortran 90 programmers should declare a handle as:

```
INCLUDE "mk1_dss.f90"

TYPE (MKL_DSS_HANDLE) handle
```

C and C++ programmers should declare a handle as:

```
#include "mkl_dss.h"

_MKL_DSS_HANDLE_t handle;
```

FORTRAN 77 programmers using compilers that support eight byte integers, should declare a handle as:

```
INCLUDE "mkl_dss.f77"

INTEGER*8 handle
```

Otherwise they should replace the `INTEGER*8` data types with the `DOUBLE PRECISION` data type.

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the error returns
- user options for the solver routines
- message severity.

Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel MKL supports the iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as . The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI Conjugate Gradient Solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI Flexible Generalized Minimal RESidual Solver, or RCI FGMRES) of linear algebraic equations and exploits the general RCI scheme described in [Dong95].

See the [Linear Solvers Basics](#) for discussion of terms and concepts related to the ISS routines.

RCI means that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user himself must perform them and pass the result to the solver. This gives the great universality to the solver as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines (see [Sparse BLAS Level 2 and Level 3](#)).

NOTE. The RCI CG solver is implemented in two versions: for system of equations with single right hand side, and for system of equations with multiple right hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and positive definite.

The FGMRES method may fail if the matrix is degenerate.

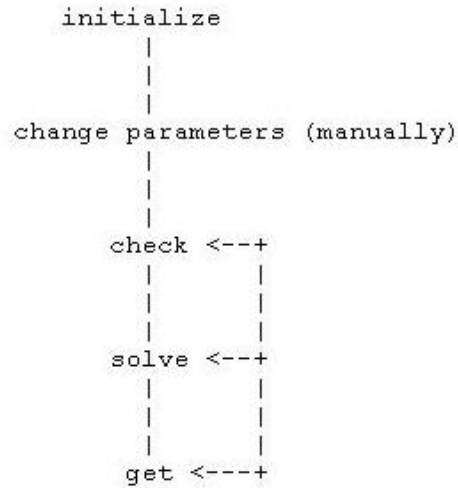

Table 8-4 lists the names of the routines, and describes their general use.

Table 8-4 RCI ISS Interface Routines

Routine	Description
<code>dcg_init</code> , <code>dcgmrhs_init</code> , <code>dfgmres_init</code>	Initializes the solver.
<code>dcg_check</code> , <code>dcgmrhs_check</code> , <code>dfgmres_check</code>	Checks the consistency and correctness of the user defined data.
<code>dcg</code> , <code>dcgmrhs</code> , <code>dfgmres</code>	Computes the approximate solution vector.
<code>dcg_get</code> , <code>dcgmrhs_get</code> , <code>dfgmres_get</code>	Retrieves the number of the current iteration.

The Intel MKL RCI ISS interface routines are normally invoked in the order listed in [Table8-4](#), with the exception of `dcg_get`, `dcgmrhs_get`, and `dfgmres_get` routines that can be invoked at any place in the code. However, in this case some precautions should be taken to avoid the wrong results. Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram in [Figure 8-3](#) indicates the typical order in which the RCI ISS interface routines can be invoked.

Figure 8-3 Typical Order for Invoking RCI ISS interface Routines

The following pseudocode shows the general schemes of using the RCI CG routines.

...

generate matrix *A*

generate preconditioner *C* (optional)

call `dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)`

change parameters in *ipar*, *dpar* if necessary

call `dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)`

1 call `dcg(n, x, b, RCI_request, ipar, dpar, tmp)`

if (*RCI_request*.eq.1) then

multiply the matrix *A* by *tmp*(1:*n*,1) and put the result in *tmp*(1:*n*,2)

It is possible to use [MKL Sparse BLAS Level 2](#) subroutines for this operation

c proceed with CG iterations

goto 1

```

endif
if (RCI_request.eq.2) then
  do the stopping test
  if (test not passed) then
c  proceed with CG iterations
    go to 1
  else
c  stop CG iterations
    goto 2
  endif
endif
if (RCI_request.eq.3) then (optional)
  apply the preconditioner C inverse to tmp(1:n,3) and put the result in tmp(1:n,4)
c  proceed with CG iterations
  goto 1
end
2 call dcg_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
  current iteration number is in itercount
  the computed approximation is in the array x

```

And the following pseudocode shows the general schemes of using the RCI FGMRES routines.

...

generate matrix *A*

generate preconditioner *C* (optional)

```

  call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
  change parameters in ipar, dpar if necessary
  call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1 call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
  if (RCI_request.eq.1) then
    multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))

```

It is possible to use [MKL Sparse BLAS Level 2](#) subroutines for this operation

```
c  proceed with FGMRES iterations
    goto 1
endif
if (RCI_request.eq.2) then
    do the stopping test
    if (test not passed) then
c  proceed with FGMRES iterations
        go to 1
    else
c  stop FGMRES iterations
        goto 2
    endif
endif
if (RCI_request.eq.3) then (optional)
apply the preconditioner  $C$  inverse to  $tmp(ipar(22))$  and put the result in  $tmp(ipar(23))$ 
c  proceed with FGMRES iterations
    goto 1
endif
if (RCI_request.eq.4) then
check the norm of the next orthogonal vector, it is contained in  $dpar(7)$ 
    if (the norm is not zero up to rounding/computational errors) then
c  proceed with FGMRES iterations
        goto 1
    else
c  stop FGMRES iterations
        goto 2
    endif
endif
```

2 call dfgmres_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

current iteration number is in *itercount*

the computed approximation is in the array *x*

Note that for the FGMRES method the array *x* initially contains the current initial approximation to the solution that can be updated only by calling the routine dfgmres_get. It updates the solution in accordance with the computations performed by the routine dfgmres.

The above pseudocodes demonstrate two main differences in the use of RCI CG and RCI FGMRES interfaces. The first difference relates to *RCI_request*=3 (different locations in the *tmp* array, which is 2-dimensional for CG and 1-dimensional for FGMRES). The second difference relates to *RCI_request*=4 (the RCI CG interface never produces *RCI_request*=4).

Code examples that use the RCI ISS interface routines to solve systems of linear equations can be found in the [Iterative Sparse Solver Code Example](#) section in the Appendix C.

CG Interface Description

All types in this documentation refer to the common Fortran types, INTEGER, and DOUBLE PRECISION.

C and C++ programmers should refer to the section [Calling Sparse Solver and Preconditioner Routines From C/C++](#) for information on mapping Fortran types to C/C++ types.

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right hand side (SRHS), and for a system of equations with multiple right hand sides (MRHS). The names of routines for a system with MRHS contain the suffix *mrhs*.

Routines Options

All of the RCI CG routines have parameters for passing various options to the routines. The values for these parameters should be specified very carefully (see [CG Common Parameters](#)), and they can be changed during computations according to the user's needs.

NOTE. Provide correct and consistent parameters to the subroutines to avoid fails or wrong results.

User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine `dcg` to compute the solution of a system of linear algebraic equations. The Intel MKL RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

CG Common Parameters

NOTE. The default and initial values listed below are assigned to the parameters by calling the `dcg_init/dcgmrhs_init` routine.

<i>n</i>	- INTEGER, this parameter sets the size of the problem in the <code>dcg_init/dcgmrhs_init</code> routine. All the other routines uses the <code>ipar(1)</code> parameter instead.
<i>x</i>	- DOUBLE PRECISION array of size <i>n</i> for SRHS, or matrix of size <i>n</i> -by- <i>nrhs</i> for MRHS. This parameter contains the current approximation to the solution. Before the first call to the <code>dcg/dcgmrhs</code> routine, it contains the initial approximation to the solution.
<i>nrhs</i>	- INTEGER, this parameter sets the number of right-hand sides for MRHS routines.
<i>b</i>	- DOUBLE PRECISION array containing a single right-hand side vector, or matrix (<i>nrhs</i> , <i>n</i>) containing right-hand side vectors.
<i>RCI_request</i>	- INTEGER, this parameter informs about the result of work of the RCI CG routines. The negative values of the parameter indicate that the routine is completed with errors or warnings. The 0 value indicates the successful completion of the task. The positive values mean that the user must perform certain actions, specifically: <div style="margin-left: 20px;"> <i>RCI_request</i>= 1 - to multiply the matrix by <i>tmp</i> (1:<i>n</i>,1), put the result in <i>tmp</i> (1:<i>n</i>,2), and return the control to the <code>dcg/dcgmrhs</code> routine; <i>RCI_request</i>= 2 - to perform the stopping tests. If they fail, return the control to the <code>dcg/dcgmrhs</code> routine. Otherwise, the solution is found and stored in the <i>x</i> array; </div>

RCI_request = 3 - for SRHS: to apply the preconditioner to *tmp(1:n,3)*, put the result in *tmp(1:n,4)*, and return the control to the *dcg* routine;
 - for MRHS: to apply the preconditioner to *tmp(:,3+ipar(3))*, put the result in *tmp(:,3)*, and return the control to the *dcgmrhs* routine.

Note that the *dcg_get*/*dcgmrhs_get* routine does not change the parameter *RCI_request*. This enables to use this routine inside the Reverse Communication computations.

ipar

- INTEGER array, of size 128 for SRHS, and of size (128+2**nrhs*) for MRHS; this parameter specifies the integer set of data for the RCI CG computations:

ipar(1) - specifies the size of the problem. The *dcg_init*/*dcgmrhs_init* routine assigns *ipar*(1)=*n*. All the other routines uses this parameter instead of *n*. There is no default value for this parameter.

ipar(2) - specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created files *dcg_errors.txt* and *dcg_check_warnings.txt* respectively. Note that if *ipar*(6) and *ipar*(7) parameters are set to 0, error and warning messages are not generated at all.

ipar(3) - for SRHS: contains the current stage of the RCI CG computations, the initial value is 1;
 - for MRHS: contains the right-hand side for which the calculations are currently performed.

WARNING. Avoid altering this variable during computations.

<i>ipar</i> (4)	- contains the current iteration number, the initial value is 0.
<i>ipar</i> (5)	- specifies the maximum number of iterations, the default value is $\min\{150, n\}$.
<i>ipar</i> (6)	- if the value is not equal to 0, the routines output error messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output error messages at all, but return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (7)	- if the value is not equal to 0, the routines output warning messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (8)	- if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine performs the stopping test for the maximum number of iterations, namely, $ipar(4) \leq ipar(5)$. Otherwise, the method is stopped and the corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the routine does not perform this stopping test. The default value is 1.
<i>ipar</i> (9)	- if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine performs the residual stopping test, namely, $dpar(5) \leq dpar(4) = dpar(1) * dpar(3) + dpar(2)$. Otherwise, the method is stopped and corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the routine does not perform this stopping test. The default value is 0.
<i>ipar</i> (10)	- if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine requests a user-defined stopping test by setting the output parameter

RCI_request=2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

NOTE. At least one of the parameters *ipar*(8)-*ipar*(10) must be set to 1.

ipar(11)

- if the value is equal to 0, the *dcg/dcgmrhs* routine runs the non-preconditioned version of the corresponding Conjugate Gradient method. Otherwise, the routine runs the preconditioned version of the Conjugate Gradient method, and requests the user to perform the preconditioning step by setting the output parameter *RCI_request*=3. The default value is 0.

ipar(11:128),
ipar(11:128+2**nrhs*)

are reserved and not used in the current RCI CG SRHS and MRHS routines respectively.

NOTE. Advanced users can define the array in the code using RCI CG SRHS as `INTEGER ipar(11)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array *ipar* with length 128 is highly recommended.

dpar

- DOUBLE PRECISION array, for SRHS of size 128, for MRHS of size (128+2**nrhs*); this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

dpar(1)

- specifies the relative tolerance. The default value is 1.0D-6.

dpar(2)

- specifies the absolute tolerance. The default value is 0.0D-0.

<code>dpar(3)</code>	- specifies the square norm of the initial residual (if it is computed in the <code>dcg/dcgmrhs</code> routine). The initial value is 0.
<code>dpar(4)</code>	- service variable equal to $dpar(1) * dpar(3) + dpar(2)$ (if it is computed in the <code>dcg/dcgmrhs</code> routine). The initial value is 0.
<code>dpar(5)</code>	- specifies the square norm of the current residual. The initial value is 0.0.
<code>dpar(6)</code>	- specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.
<code>dpar(7)</code>	- contains the <i>alpha</i> parameter of the CG method. The initial value is 0.0.
<code>dpar(8)</code>	- contains the <i>beta</i> parameter of the CG method, it is equal to $dpar(5) / dpar(6)$. The initial value is 0.0.
<code>dpar(9:128),</code> <code>dpar(9:128+2*nrhs)</code>	are reserved and not used in the current RCI CG SRHS and MRHS routines respectively.

NOTE. Advanced users can define this array in the code using RCI CG SRHS as `DOUBLE PRECISION dpar(8)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array `dpar` with length 128 is highly recommended.

`tmp`

- `DOUBLE PRECISION` array of size $(n, 4)$ for SRHS, and $(n, 3+nrhs)$ for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

<code>tmp(:, 1)</code>	- specifies the current search direction. The initial value is 0.0.
------------------------	---------------------------------------------------------------------

<code>tmp(:, 2)</code>	- contains the matrix multiplied by the current search direction. The initial value is 0.0.
<code>tmp(:, 3)</code>	- contains the current residual. The initial value is 0.0.
<code>tmp(:, 4)</code>	- contains the inverse of the preconditioner applied to the current residual. There is no initial value for this parameter.

NOTE. Advanced users can define this array in the code using RCI CG SRHS as `DOUBLE PRECISION tmp(n, 3)` if they run only non-preconditioned CG iterations.

FGMRES Interface Description

All types in this documentation refer to the common Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers should refer to the section [Calling Sparse Solver Routines From C/C++](#) for information on mapping Fortran types to C/C++ types.

Routines Options

All of the RCI FGMRES routines have parameters for passing various options to the routines. The values for these parameters should be specified very carefully (see [FGMRES Common Parameters](#)), and they can be changed during computations according to the user's needs.

NOTE. Provide correct and consistent parameters to the subroutines to avoid fails or wrong results.

User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfgmres` to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL RCI FGMRES routines do not make copies of the user input arrays.

FGMRES Common Parameters

NOTE. The default and initial values listed below are assigned to the parameters by calling the `dfgmres_init` routine.

<i>n</i>	- INTEGER, this parameter sets the size of the problem in the <code>dfgmres_init</code> routine. All the other routines uses <code>ipar(1)</code> parameter instead.
<i>x</i>	- DOUBLE PRECISION array, this parameter contains the current approximation to the solution vector. Before the first call to the <code>dfgmres</code> routine, it contains the initial approximation to the solution vector.
<i>b</i>	- DOUBLE PRECISION array, this parameter contains the right-hand side vector. Depending on user requests, it may later contain the approximate solution.
<i>RCI_request</i>	- INTEGER, this parameter informs about the result of work of the RCI FGMRES routines. The negative values of the parameter indicate that the routine is completed with errors or warnings. The 0 value indicates the successful completion of the task. The positive values mean that the user must perform certain actions, specifically: <div style="margin-left: 20px;"> <i>RCI_request</i>= 1 - multiply the matrix by <code>tmp(ipar(22))</code>, put the result in <code>tmp(ipar(23))</code>, and return the control to the <code>dfgmres</code> routine; <i>RCI_request</i>= 2 - perform the stopping tests. If they fail, return the control to the <code>dfgmres</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine; </div>

	<code>RCI_request= 3</code>	- apply the preconditioner to <code>tmp(ipar(22))</code> , put the result in <code>tmp(ipar(23))</code> , and return the control to the <code>dfgmres</code> routine.
	<code>RCI_request= 4</code>	- check if the norm of the current orthogonal vector is not zero within the rounding/computational errors. Return the control to the <code>dfgmres</code> routine if it is not zero, otherwise complete the solution process by calling <code>dfgmres_get</code> routine.
<code>ipar(128)</code>		- INTEGER array, this parameter specifies the integer set of data for the RCI FGMRES computations:
	<code>ipar(1)</code>	- specifies the size of the problem. The <code>dfgmres_init</code> routine assigns <code>ipar(1)=n</code> . All the other routines uses this parameter instead of <code>n</code> . There is no default value for this parameter.
	<code>ipar(2)</code>	- specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file <code>MKL_RCI_FGMRES_Log.txt</code> . Note that if <code>ipar(6)</code> and <code>ipar(7)</code> parameters are set to 0, error and warning messages are not generated at all.
	<code>ipar(3)</code>	- contains the current stage of the RCI FGMRES computations, the initial value is 1.
<div>  WARNING. Avoid altering this variable during computations. </div>		
	<code>ipar(4)</code>	- contains the current iteration number. The initial value is 0.
	<code>ipar(5)</code>	- specifies the maximum number of iterations. The default value is <code>min {150,n}</code> .

<i>ipar</i> (6)	- if the value is not equal to 0, the routines output error messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output error messages at all, but return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (7)	- if the value is not equal to 0, the routines output warning messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (8)	- if the value is not equal to 0, the <i>dfmres</i> routine performs the stopping test for the maximum number of iterations, namely, $ipar(4) \leq ipar(5)$. Otherwise, the method is stopped and the corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the <i>dfgmres</i> routine does not perform this stopping test. The default value is 1.
<i>ipar</i> (9)	- if the value is not equal to 0, the <i>dfgmres</i> routine performs the residual stopping test, namely, $dpar(5) \leq dpar(4) = dpar(1) \cdot dpar(3) + dpar(2)$. If the criterion is met, the method is stopped and corresponding value is assigned to the output parameter <i>RCI_request</i> . If the value is 0, the <i>dfgmres</i> routine does not perform this stopping test. The default value is 0.
<i>ipar</i> (10)	- if the value is not equal to 0, the <i>dfgmres</i> routine requests for the user defined stopping test by setting <i>RCI_request</i> =2. If the value is 0, the <i>dfgmres</i> routine does not perform the user defined stopping test. The default value is 1.

NOTE. At least one of the parameters $ipar(8)$ - $ipar(10)$ must be set to 1.

$ipar(11)$

- if the value is equal to 0, the `dfgmres` routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests the user to perform the preconditioning step by setting the output parameter $RCI_request=3$. The default value is 0.

$ipar(12)$

- if the value is not equal to 0, the `dfgmres` routine performs the automatic test for zero norm of the currently generated vector, namely, $dpar(7) \leq dpar(8)$, where $dpar(8)$ contains the tolerance value. Otherwise, the routine requests the user to perform this check by setting the output parameter $RCI_request=4$. The default value is 0.

$ipar(13)$

- if the value is equal to 0, the `dfgmres_get` routine updates the solution to the vector x according to the computations done by the `dfgmres` routine. If the value is positive, the routine writes the solution to the right hand side vector b . If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0

NOTE. Advanced users may use the `dfgmres_get` routine at any place in the code. In this case special attention should be paid to the parameter `ipar(13)`. The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter `ipar(13)` is not equal to zero. If `ipar(13)` is positive, then the updated solution overwrites the right hand side in the vector b . If the user wants to run the restarted version of FGMRES with the same right hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive `ipar(13)`.

`ipar(14)`

- contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

WARNING. Avoid altering this variable during computations.

`ipar(15)`

- specifies the length of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, the user must assign the number of iterations to `ipar(15)` before the restart. The default value is $\min\{150, n\}$, that is, by default the non-restarted version of FGMRES method is used.

`ipar(16)`

- service variable, specifies the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see [Matrix Arguments](#) in the Appendix B for details) is started in the `tmp` array.

<i>ipar</i> (17)	- service variable, specifies the location of the rotation cosines from which the vector of cosines is started in the <i>tmp</i> array.
<i>ipar</i> (18)	- service variable, specifies the location of the rotation sines from which the vector of sines is started in the <i>tmp</i> array.
<i>ipar</i> (19)	- service variable, specifies the location of the rotated residual vector from which the vector is started in the <i>tmp</i> array.
<i>ipar</i> (20)	- service variable, specifies the location of the least squares solution vector from which the vector is started in the <i>tmp</i> array.
<i>ipar</i> (21)	- service variable, specifies the location of the set of preconditioned vectors from which the set is started in the <i>tmp</i> array. The memory locations in the <i>tmp</i> array starting from <i>ipar</i> (21) are used only for the preconditioned FGMRES method.
<i>ipar</i> (22)	- specifies the memory location from which the first vector (source) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.
<i>ipar</i> (23)	- specifies the memory location from which the second vector (source) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.
<i>ipar</i> (24:128)	are reserved and not used in the current RCI FGMRES routines.

NOTE. Advanced users can define the array in the code as `INTEGER ipar(23)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array *ipar* with length 128 is highly recommended.

<code>dpar(128)</code>	- DOUBLE PRECISION array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:
<code>dpar(1)</code>	- specifies the relative tolerance. The default value is 1.0D-6.
<code>dpar(2)</code>	- specifies the absolute tolerance. The default value is 0.0D-0.
<code>dpar(3)</code>	- specifies the Euclidean norm of the initial residual (if it is computed in the <code>dfgmres</code> routine). The initial value is 0.0.
<code>dpar(4)</code>	- service variable equal to $dpar(1) * dpar(3) + dpar(2)$ (if it is computed in the <code>dfgmres</code> routine). The initial value is 0.0.
<code>dpar(5)</code>	- specifies the Euclidean norm of the current residual. The initial value is 0.0.
<code>dpar(6)</code>	- specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.
<code>dpar(7)</code>	- contains the norm of the generated vector. The initial value is 0.0.
<div>  NOTE. For reference only: in terms of [Saad03] this parameter is the coefficient $h_{k+1,k}$ of the Hessenberg matrix. </div>	
<code>dpar(8)</code>	- contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0D-12.
<code>dpar(9:128)</code>	are reserved and not used in the current RCI FGMRES routines.

NOTE. Advanced users can define this array in the code as follows: `DOUBLE PRECISION dpar(8)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array `dpar` with length 128 is highly recommended.

tmp

-DOUBLE PRECISION array of size $((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1))$, this parameter is used to supply the double precision temporary space for the RCI FGMRES computations, specifically:

tmp(1:ipar(16)-1) - contains the sequence of generated by the FGMRES method vectors. The initial value is 0.0 for the first part of this memory of length *n*;

tmp(ipar(16):ipar(17)-1) contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of *tmp* array.

tmp(ipar(17):ipar(18)-1) - contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.

tmp(ipar(18):ipar(19)-1) contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.

tmp(ipar(19):ipar(20)-1) contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.

tmp(ipar(20):ipar(21)-1) contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of *tmp* array.

`tmp(ipar(21):)` contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of `tmp` array is not used if non-preconditioned version of FGMRES method is called. There is no initial value for this part of `tmp` array.

NOTE. Advanced users can define this array in the code as `DOUBLE PRECISION tmp((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1))` if they run only non-preconditioned FGMRES iterations.

dcg_init

Initializes the solver.

Syntax

```
dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel MKL RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set these parameters directly in the corresponding routines.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	INTEGER. Contains the size of the problem, and the sizes of arrays x and b .
x	DOUBLE PRECISION array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
b	DOUBLE PRECISION array of size n . Contains the right-hand side vector.

Output Parameters

$RCI_request$	INTEGER. Informs about result of work of the routine.
$ipar$	INTEGER array of size 128. Refer to the CG Common Parameters .
$dpar$	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
tmp	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

$RCI_request = 0$	The routine completes the task normally.
$RCI_request = -10000$	The routine fails to complete the task.

dcg_check

Checks consistency and correctness of the user defined data.

Syntax

`dcg_check(n , x , b , $RCI_request$, $ipar$, $dpar$, tmp)`

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the method. Advanced users may skip this operation if they are sure that the correct data is specified in the solver parameters.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcg_init` routine.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and size of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.
<i>RCI_request</i> = -1100	The routine is interrupted, errors occur.

`RCI_request= -1001`

The routine returns some warning messages.

`RCI_request= -1010`

The routine changes some parameters to make them consistent or correct.

`RCI_request= -1011`

The routine returns some warning messages and changes some parameters.

dcg

Computes the approximate solution vector.

Syntax

`dcg(n, x, b, RCI_request, ipar, dpar, tmp)`

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcg` computes the approximate solution vector using the CG method [Young71].

The routine `dcg` uses the value that was in the vector `x` before the first call as an initial approximation to the solution. The parameter `RCI_request` informs the user about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcg_init` routine.

Input Parameters

<code>n</code>	INTEGER. Contains the size of the problem, and size of arrays <code>x</code> and <code>b</code> .
<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the initial approximation to the solution vector.
<code>b</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the right-hand side vector.
<code>tmp</code>	DOUBLE PRECISION array of size <code>(n, 4)</code> . Refer to the CG Common Parameters .

Output Parameters

<code>RCI_request</code>	INTEGER. Informs about result of work of the routine.
--------------------------	-------------------------------------------------------

<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the updated approximation to the solution vector.
<i>ipar</i>	INTEGER array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> =0	The routine completes task normally, the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the comments to the <i>RCI_request</i> = 2.
<i>RCI_request</i> =-1	The routine is interrupted because the maximal number of iterations is reached, but the relative stopping criterion is not met - this situation occurs only if both tests are requested by the user.
<i>RCI_request</i> =-2	The routine is interrupted because attempt to divide by zero occurs. This situation happens if the matrix is (almost) non-positive definite.
<i>RCI_request</i> =- 10	The routine is interrupted because the residual norm is invalid. Probably, the value <i>dpar</i> (6) was altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> =-11	The routine is interrupted because it enters the infinite cycle. Probably, the values <i>ipar</i> (8), <i>ipar</i> (9), <i>ipar</i> (10) were altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> = 1	Requests the user to multiply the matrix by <i>tmp</i> (1: <i>n</i> ,1), put the result in the <i>tmp</i> (1: <i>n</i> ,2), and return the control back to the routine <i>dcg</i> .

`RCI_request= 2`

Requests the user to perform the stopping tests. If they fail, the control must be returned back to the `dcg` routine. Otherwise, the solution is found and stored in the vector `x`.

`RCI_request= 3`

Requests the user to apply the preconditioner to `tmp(:, 3)`, put the result in the `tmp(:, 4)`, and return the control back to the routine `dcg`.

dcg_get

Retrieves the number of the current iteration.

Syntax

`dcg_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcg_get` retrieves the current iteration number of the solutions process.

Input Parameters

<code>n</code>	INTEGER. Contains the size of the problem, and the sizes of arrays <code>x</code> and <code>b</code> .
<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the initial approximation vector to the solution.
<code>b</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the right-hand side vector.
<code>RCI_request</code>	INTEGER. This parameter is not used.
<code>ipar</code>	INTEGER array of size 128. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Output Parameters

itercount INTEGER argument. Contains the value of the current iteration number.

Return Values

The routine `dcg_get` does not return any value.

dcgmrhs_init

Initializes the RCI CG solver with MHRS.

Syntax

```
dcgmrhs_init(n, x, nrhs, b, method, RCI_request, ipar, dpar, tmp)
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcgmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel MKL RCI CG with multiple right hand sides (MRHS) routines use the values of all parameters that are returned by `dcgmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the corresponding routines.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

NOTE. To use this routine with the name `dcg_init`, switch on the compiler preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Input Parameters

n INTEGER. Contains the size of the problem, and the sizes of arrays *x* and *b*.

<i>x</i>	DOUBLE PRECISION matrix of size <i>n</i> -by- <i>nrhs</i> . Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <i>b</i> .
<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size (<i>nrhs</i> , <i>n</i>). Contains the right-hand side vectors.
<i>method</i>	INTEGER. Specifies the method of solution: 1 - CG with multiple right hand sides; default value 2 - Block-CG (not supported now).

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size (<i>n</i> , <i>3+nrhs</i>). Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.
<i>RCI_request</i> = -10000	The routine fails to complete the task.

dcgmrhs_check

Checks consistency and correctness of the user defined data.

Syntax

```
dcgmrhs_check(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcgmrhs_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcgmrhs`. However this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the method. Advanced users may skip this operation if they are sure that the correct data is specified in the solver parameters.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcgmrhs_init` routine.

NOTE. To use this routine with the name `dcg_check`, switch on the compiler preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION matrix of size <i>n</i> by <i>nrhs</i> . Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <i>b</i> .
<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size (<i>nrhs</i> , <i>n</i>). Contains the right-hand side vectors.

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .

tmp DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the [CG Common Parameters](#).

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.
<i>RCI_request</i> = -1100	The routine is interrupted, errors occur.
<i>RCI_request</i> = -1001	The routine returns some warning messages.
<i>RCI_request</i> = -1010	The routine changes some parameters to make them consistent or correct.
<i>RCI_request</i> = -1011	The routine returns some warning messages and changes some parameters.

dcgmrhs

Computes the approximate solution vectors.

Syntax

`dcgmrhs(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)`

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcgmrhs` computes the approximate solution vectors using the CG with multiple right hand sides (MRHS) method [Young71]. The routine `dcgmrhs` uses the value that was in the *x* before the first call as an initial approximation to the solution. The parameter *RCI_request* informs the user about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcgmrhs_init` routine.

NOTE. To use this routine with the name `dcg`, the user must switch on the compiler's preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION matrix of size <i>n</i> -by- <i>nrhs</i> . Contains the initial approximation to the solution vectors.
<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size (<i>nrhs</i> , <i>n</i>). Contains the right-hand side vectors.
<i>tmp</i>	DOUBLE PRECISION array of size (<i>n</i> , 3+ <i>nrhs</i>). Refer to the CG Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>x</i>	DOUBLE PRECISION matrix of size <i>n</i> -by- <i>nrhs</i> . Contains the updated approximation to the solution vectors.
<i>ipar</i>	INTEGER array of size (128+2* <i>nrhs</i>). Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size (128+2* <i>nrhs</i>). Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size (<i>n</i> , 3+ <i>nrhs</i>). Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> =0	The routine completes task normally, the solution is found and stored in the matrix <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the comments to the <i>RCI_request</i> = 2.
<i>RCI_request</i> =-1	The routine is interrupted because the maximal number of iterations is reached, but the relative stopping criterion is not satisfied. This situation occurs only if both tests are requested by the user.

`RCI_request=-2`

The routine is interrupted because attempt to divide by zero occurs. This happens if the matrix is (almost) non-positive definite.

`RCI_request=- 10`

The routine is interrupted because the residual norm is invalid. Probably, the value `dpar(6)` was altered outside of the routine, or the routine `dcgmrhs_rhs_check` was not called.

`RCI_request=-11`

The routine is interrupted because it enters the infinite cycle. Probably, the values `ipar(8)`, `ipar(9)`, `ipar(10)` were altered outside of the routine, or the routine `dcgmrhs_check` was not called.

`RCI_request= 1`

Requests the user to multiply the matrix by `tmp(1:n,1)`, put the result in the `tmp(1:n,2)`, and return the control back to the routine `dcgmrhs`.

`RCI_request= 2`

Requests the user to perform the stopping tests. If they fail, the control must be returned back to the routine `dcgmrhs`. Otherwise, the solution is found and stored in the matrix `x`.

`RCI_request= 3`

Requests the user to apply the preconditioner to `tmp(:,3+ipar(3))`, put the result in `tmp(:,3)`, and return the control back to the routine `dcgmrhs`.

dcgmrhs_get

Retrieves the number of the current iteration.

Syntax

`dcgmrhs_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface. The routine `dcgmrhs_get` retrieves the current iteration number of the solving process.

NOTE. To use this routine with the name `dcg_get`, switch on the compiler preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION matrix of size <i>n</i> -by- <i>nrhs</i> . Contains the initial approximation to the solution vectors.
<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size (<i>nrhs</i> , <i>n</i>). Contains the right-hand side .
<i>RCI_request</i>	INTEGER. This parameter is not used.
<i>ipar</i>	INTEGER array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size (<i>n</i> , <i>3+nrhs</i>). Refer to the CG Common Parameters .

Output Parameters

<i>itercount</i>	INTEGER argument. Contains the value of the current iteration number.
------------------	-----------------------------------------------------------------------

Return Values

The routine `dpgmrhs_get` does not return any value.

dfgmres_init

Initializes the solver.

Syntax

```
dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel MKL RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users may skip this step and set the values to these parameters directly in the corresponding routines.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.
<i>RCI_request</i> = -10000	The routine fails to complete the task.

dfgmres_check

Checks consistency and correctness of the user defined data.

Syntax

```
dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dfgmres_check` checks consistency and correctness of the parameters to be passed to the solver routine `dfgmres`. However this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the method. Advanced users may skip it if they are sure that the correct data is specified in the solver parameters.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
--------------------	-------------------------------------------------------

<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.
<i>RCI_request</i> = -1100	The routine is interrupted, errors occur.
<i>RCI_request</i> = -1001	The routine returns some warning messages.
<i>RCI_request</i> = -1010	The routine changes some parameters to make them consistent or correct.
<i>RCI_request</i> = -1011	The routine returns some warning messages and changes some parameters.

dfgmres

Makes the FGMRES iterations.

Syntax

`dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)`

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dfgmres` performs the FGMRES iterations [Saad03]. The routine `dfgmres` uses the value that was in the vector `x` before the first call as an initial approximation to the solution. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter `ipar(13)` is not equal to 0 (default value). Note that the updated solution overwrites the right hand side in the vector `b` if the parameter `ipar(13)` is positive, and the restarted version of the FGMRES method can not be run. If the right hand side should be kept, it must be saved in a different memory location before the first call to the `dfgmres_get` routine with a positive `ipar(13)`.

The parameter *RCI_request* informs the user about the task completion and requests results of certain operations that are needed to the solver.

Note that lengths of all the vectors are assumed to have been defined in a previous call to the *dfgmres_init* routine.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector.
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> = 0	The routine completes task normally, the solution is found. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the comments to the <i>RCI_request</i> = 2 or 4.
<i>RCI_request</i> = -1	The routine is interrupted because the maximal number of iterations is reached, but the relative stopping criterion is not met. This situation occurs only if both tests are requested by the user.

RCI_request = -10

The routine is interrupted because attempt to divide by zero occurs. Normally it happens if the matrix is (almost) degenerate. However it may happen if the parameter *dpar* is altered by mistake, or if the method is not stopped when the solution is found.

RCI_request = -11

The routine is interrupted because it enters the infinite cycle. Probably, the values *ipar*(8), *ipar*(9), *ipar*(10) were altered outside of the routine, or the *dfgmres_check* routine was not called.

RCI_request = -12

The routine is interrupted because errors are found in the method parameters. Normally this happens if the parameters *ipar* and *dpar* are altered by mistake outside the routine.

RCI_request = 1

Requests the user to multiply the matrix by *tmp(ipar(22))*, put the result in the *tmp(ipar(23))*, and return the control back to the routine *dfgmres*.

RCI_request = 2

Requests the user to perform the stopping tests. If they fail, the control back must be returned to the *dfgmres* routine. Otherwise, the FGMRES solution is found, and the *fgmres_get* routine can be run to update the computed solution in the vector *x*.

RCI_request = 3

Requests the user to apply the inverse preconditioner to *ipar(22)*, put the result in the *ipar(23)*, and return the control back to the routine *dfgmres*.

RCI_request = 4

Requests the user to check the norm of the currently generated vector. If it is not zero within the computational/rounding errors, the control must be returned back to the *dfgmres* routine. Otherwise, the FGMRES solution is found, and the *dfgmres_get* routine can be run to update the computed solution in the vector *x*.

dfgmres_get

Retrieves the number of the current iteration and updates the solution.

Syntax

```
dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dfgmres_get` retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the `dfgmres` routine. To retrieve the current iteration number only, set the parameter `ipar(13) = -1` beforehand. This is normally recommended to do to proceed further with the computations. If the intermediate solution is needed, the method parameters must be set properly, see for details [FGMRES Common Parameters](#) and [Iterative Sparse Solver Code Examples](#) section in the Appendix C.

Input Parameters

<code>n</code>	INTEGER. Contains the size of the problem, and the sizes of the arrays <code>x</code> and <code>b</code> .
<code>ipar</code>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $((2 * ipar(15) + 1) * n + ipar(15) * ipar(15) + 9) / 2 + 1$. Refer to the FGMRES Common Parameters .

Output Parameters

<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . If <code>ipar(13) = 0</code> , it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
----------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . If <i>ipar</i> (13) > 0, it contains the updated approximation to the solution according to the computations done in <i>dfgmres</i> routine. Otherwise, it is not changed.
<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>itercount</i>	INTEGER argument. Contains the value of the current iteration number.

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.
<i>RCI_request</i> = -12	The routine is interrupted because errors are found in the method parameters. Normally this happens if the parameters <i>ipar</i> and <i>dpar</i> are altered by mistake outside the routine.
<i>RCI_request</i> = -10000	The routine fails to complete the task.

Implementation Details

Several aspects of the Intel MKL RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel MKL RCI ISS language-specific header files. Currently, there is one language specific header file for C programs.

This language-specific header file defines function prototypes and they are the following:

```
void dcg_init(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);

void dcg_check(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);

void dcg(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp);

void dcg_get(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp, int *itercount);

void dcgmrhs_init(int *n, double *x, int *nRhs, double *b, int *method, int
*rci_request, int *ipar, double dpar, double *tmp);

void dcgmrhs_check(int *n, double *x, int *nRhs, double *b, int *rci_request,
int *ipar, double dpar, double *tmp);
```

```
void dcgmrhs(int *n, double *x, int *nRhs, double *b, int *rci_request, int
*ipar, double dpar, double *tmp);

void dcgmrhs_get(int *n, double *x, int *nRhs, double *b, int *rci_request,
int *ipar, double dpar, double *tmp, int *itercount);

void dfgmres_init(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);

void dfgmres_check(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);

void dfgmres(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);

void dfgmres_get(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp, int *itercount);
```

NOTE. Intel MKL does not support the RCI ISS interface without the language specific header file included.

Preconditioners based on Incomplete LU Factorization Technique

Usually, preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms ‘preconditioner’ and ‘accelerator’ are synonyms, hereafter only ‘preconditioner’ is used.

Currently, Intel MKL provides two preconditioners, ILU0 and ILUT, for the sparse matrix presented only in the format accepted in the Intel MKL direct sparse solvers (three-array variation of the CSR storage format, see [Sparse Matrix Storage Format](#) section). The used algorithms are described in [Saad03].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: low triangular and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT preconditioner is that it saves the resulting entry of the preconditioner if the entry satisfies two conditions simultaneously: the value of the entry is greater than the product of the given tolerance and matrix row norm, and the entry is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel MKL RCI FGMRES solver (see [Sparse Solver Routines](#)). Avoid using this preconditioners with MKL RCI CG solver because in general, they produce non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel MKL triangular solver routine `mkl_dcsrtrsv` must be applied twice: for the low triangular part of the preconditioner, and then for its upper triangular part.

NOTE. Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. The result of the preconditioner routine can be checked only in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial guess, and even ruin the convergence. It is user's responsibility to carefully use a suitable preconditioner.

General Scheme of Using ILUT and RCI FGMRES Routines

The scheme is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. All these differences can be seen in the example codes for both preconditioners in the [Preconditioner Code Examples](#) in the Appendix C.

The following pseudocode shows the general scheme of using the ILUT preconditioner in the RCI FGMRES context.

...

generate matrix *A*

generate preconditioner *C* (optional)

```
call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

```
change parameters in ipar, dpar if necessary
```

```
call dcsrilit(n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar,  
ierr)
```

```
call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
```

```

1  call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
   if (RCI_request.eq.1) then
       multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
c   proceed with FGMRES iterations
       goto 1
   endif
   if (RCI_request.eq.2) then
       do the stopping test
       if (test not passed) then
c   proceed with FGMRES iterations
           go to 1
       else
c   stop FGMRES iterations.
           goto 2
       endif
   endif
   if (RCI_request.eq.3) then
c   Below, trvec is an intermediate vector of length at least n
c   Here is the recommended use of the result produced by the ILUT routine.
c   via standard Intel MKL Sparse Blas solver routine mkl_dcsrtrsv.
       call mkl_dcsrtrsv('L','N','U', n, bilut, ibilut, jbilut,
tmp(ipar(22)), trvec)
       call mkl_dcsrtrsv('U','N','N', n, bilut, ibilut, jbilut, trvec,
tmp(ipar(23)))
c   proceed with FGMRES iterations
       goto 1
   endif
   if (RCI_request.eq.4) then

```

```

        check the norm of the next orthogonal vector, it is contained in dpar(7)
        if (the norm is not zero up to rounding/computational errors) then
c   proceed with FGMRES iterations
            goto 1
        else
c   stop FGMRES iterations
            goto 2
        endif
    endif
2 call dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
current iteration number is in itercount
the computed approximation is in the array x

```

ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel MKL preconditioner routines are discussed in the [Linear Solvers Basics](#).

In this section the FORTRAN style notations are used.

All types in this documentation refer to the standard Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers should refer to the section [Calling Sparse Solver Routines From C/C++](#) for information on mapping Fortran types to C/C++ types.

User Data Arrays

The preconditioner routines take arrays of user data as input, for example, user arrays representing the original matrix. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL preconditioner routines do not make copies of the user input arrays.

Common Parameters

The preconditioners have parameters for passing various options to the routine. The values for these parameters should be specified very carefully. These values can be changed during computations according to the user's needs.

Some parameters are common with the [FGMRES Common Parameters](#). Only the routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

For the ILU0 preconditioner:

ipar(2) - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise the error messages are written to the newly created file `MKL_PREC_log.txt`. Note if the parameter *ipar*(6) is set to 0, then error messages are not generated at all.

ipar(6) - if its value is not equal to 0, the ILU0 routine returns error messages in accordance with the parameter *ipar*(2). Otherwise, the routine does not generate error messages at all, but returns a negative value of the parameter *ierr*. The default value is 1.

For the ILUT preconditioner:

ipar(2) - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise the error messages are written to the newly created file `MKL_PREC_log.txt`. Note if the parameter *ipar*(6) is set to 0, error messages are not generated at all.

ipar(6) - if its value is not equal to 0, the ILUT routine returns error messages in accordance with the parameter *ipar*(2). Otherwise, the routine does not generate error messages at all, but returns a negative value of the parameter *ierr*. The default value is 1.

ipar(7) - if its value is greater than 0, the ILUT routine generates warning messages in accordance with the parameter *ipar*(2) and continues calculations. Otherwise, if its value is equal to 0, the routine returns a positive value of the parameter *ierr*, if its value is less than 0, the routine generates a warning message in accordance with the parameter *ipar*(2) and returns a positive value of the parameter *ierr*. The default value is 1.

NOTE. Users must provide correct and consistent parameters to the routine to avoid fails or wrong results.

dcsrilu0

ILU0 preconditioner based on incomplete LU factorization of a sparse matrix in the CSR format (PARDISO variation).

Syntax

Fortran:

```
call dcsrilu0(n, a, ia, ja, bilu0, ipar, dpar, ierr)
```

C:

```
dcsrilu0(&n, a, ia, ja, bilu0, ipar, dpar, &ierr);
```

Input Parameters

<i>n</i>	INTEGER. Size (number of rows or columns) of the original square <i>n</i> -by- <i>n</i> -matrix <i>A</i> .
<i>a</i>	DOUBLE PRECISION. Array containing the set of elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to values array description in the Sparse Matrix Storage Format section for more details.
<i>ia</i>	INTEGER. Array of size $(n+1)$ containing begin indices of rows of matrix <i>A</i> such that <i>ia</i> (<i>I</i>) is the index in the array <i>A</i> of the first non-zero element from the row <i>I</i> . The value of the last element <i>ia</i> (<i>n</i> +1) is equal to the number of non-zeros in the matrix <i>A</i> plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format section for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its size is equal to the size of the array <i>a</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format section for more details.

NOTE. Column indices should be put in increasing order for each row of matrix.

ipar

INTEGER array of size 128. This parameter is used to specify the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the *ipar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

ipar(31) - specifies how the routine operates if zero diagonal element occurs during calculation. If this parameter is set to 0 (default value set by the routine `dfgmres_init`) then that the calculations are stopped and the routine returns non-zero error value. Otherwise the value of the diagonal element is set to the specified value and the calculations are continued.

NOTE. Advanced users can define this array in the code as follows:
 INTEGER *ipar*(31). However, to guarantee the compatibility with the future releases of the Intel MKL it is highly recommended to declare the array *ipar* of length 128.

dpar

DOUBLE PRECISION array of size 128. This parameter is used to specify the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

dpar(31) - specifies the small value that is compared with the diagonal elements during calculations; if the value of the diagonal element is smaller, then it is set

to `dpar(32)`, or the calculations are stopped, in accordance with `ipar(31)`; the default value is 1.0D-16

NOTE. This parameter can be set to the negative value, because its absolute value is actually used in calculations.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

`dpar(32)`

- specifies the value that is assigned to the diagonal element if its value is less than `dpar(31)` (see above); the default value is 1.0D-10

NOTE. Advanced users can define this array in the code as follows:
`DOUBLE PRECISION dpar(32).`
 However, to guarantee the compatibility with the future releases of the Intel MKL it is highly recommended to declare the array `dpar` of length 128.

Output Parameters

`bilu0`

DOUBLE PRECISION. Array *B* stored in the PARDISO CSR format containing non-zero elements of the resulting preconditioning matrix. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details.

ierr INTEGER. Error flag, informs about the routine completion status.

NOTE. To present the resulting preconditioning matrix in the CSR format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcsrilu0` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the CSR format accepted in PARDISO:

$A \sim B = L * U$, where L is a low triangular matrix with unit diagonal, U is an upper triangular matrix with non-unit diagonal, and the portrait of the original matrix A is used to store the incomplete factors L and U .

Return Values

<i>ierr</i> =0	The routine completed task normally.
<i>ierr</i> =-101	The routine is interrupted, the error occurs: at least one diagonal element is omitted from the matrix in CSR format (see Sparse Matrix Storage Format).
<i>ierr</i> =-102	The routine is interrupted because the matrix contains zero diagonal element, routine can not perform operations.
<i>ierr</i> =-103	The routine is interrupted as the matrix contains too small diagonal element, and an overflow may occur because of the division by its value required to complete the task, or a bad approximation to ILU0 with use of this element will be computed.
<i>ierr</i> =-104	The routine is interrupted because the memory is insufficient for the internal work array.
<i>ierr</i> =-105	The routine is interrupted because the input matrix size n is less than or equal to 0.
<i>ierr</i> =-106	The routine is interrupted because the the column indices <i>ja</i> are placed in not increasing order.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilu0 (n, a, ia, ja, bilu0, ipar, dpar, ierr)
  INTEGER n, ierr, ipar(128)
  INTEGER ia(*), ja(*)
  DOUBLE PRECISION a(*), bilu0(*), dpar(128)
```

C:

```
void dcsrilu0 (int *n, double *a, int *ia, int *ja, double *bilu0, int *ipar, double *dpar,
  int *ierr);
```

dcsrilut

ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.

Syntax

Fortran:

```
call dcsrilut(n, a, ia, ja, bilut, bilut, ibilut, jbilut, tol, maxfil, ipar,
  dpar, ierr)
```

C:

```
dcsrilut(&n, a, ia, ja, bilut, bilut, ibilut, jbilut, &tol, &maxfil, ipar,
  dpar, &ierr);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine `dcsrilut` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L * U$, where L is a low triangular matrix with unit diagonal, U is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors L and U :

- 1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter *tol*, and
- 2) the number of the non-zero elements in each row of the resulting *L* and *U* factors must not be greater than the value of the parameter *maxfil*.

Input Parameters

<i>n</i>	INTEGER. Size (number of rows or columns) of the original square <i>n</i> -by- <i>n</i> matrix <i>A</i> .
<i>a</i>	DOUBLE PRECISION. Array containing all non-zero elements of the matrix <i>A</i> . The length of the array is equal to their number. Refer to <i>values</i> array description in the Sparse Matrix Storage Format section for more details.
<i>ia</i>	INTEGER. Array of size $(n+1)$ containing indices of non-zero elements in the array <i>A</i> . <i>ia</i> (<i>I</i>) is the index of the first non-zero element from the row <i>I</i> . The value of the last element <i>ia</i> (<i>n</i> +1) is equal to the number of non-zeros in the matrix <i>A</i> plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format section for more details.
<i>ja</i>	INTEGER. Array of size equal to the size of the array <i>a</i> . This array contains the column numbers for each non-zero element of the matrix <i>A</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format section for more details.

NOTE. Column numbers must be in increasing order for each row of matrix.

<i>tol</i>	DOUBLE PRECISION. Tolerance for threshold criterion for the resulting entries of the preconditioner.
<i>maxfil</i>	INTEGER. Maximum fill-in, half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner can not exceed $(2*maxfil+1)$.

ipar

INTEGER array of size *128*. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the *ipar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.

ipar(31) - specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter *tol*. If *ipar*(31) = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to the certain value (see description of the parameter *dpar*(31) below), and the calculation continues.

NOTE. There is no default value for *ipar*(31) entry even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

NOTE. Advanced users can define this array in the code as `INTEGER ipar(31)`. However, to guarantee the compatibility with the future releases of the Intel MKL, declare the array *ipar* of length 128.

dpar

DOUBLE PRECISION array of size *128*. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

dpar(31) - specifies the value that being multiplied by the matrix row norm is assigned to those diagonal elements whose value is less than the matrix row norm multiplied by the value of the parameter *tol*, if the calculation is not stopped in accordance with *ipar*(31).

NOTE. There is no default value for *dpar*(31) entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

NOTE. Advanced users can define this array in the code as `DOUBLE PRECISION dpar(31)`. However, to guarantee the compatibility with the future releases of the Intel MKL, declare the array *dpar* of length 128.

Output Parameters

bilut

DOUBLE PRECISION. Array *B* containing non-zero elements of the resulting preconditioning matrix, stored format accepted in the direct sparse solvers. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details. The size of the array is equal to $(2*maxfil+1)*n-maxfil*(maxfil+1)+1$.

NOTE. Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

<i>ibilut</i>	INTEGER. Array of size $(n+1)$ containing indices of non-zero elements in the array <i>B</i> . <i>ibilut</i> (<i>I</i>) is the index of the first non-zero element from the row <i>I</i> . The value of the last element <i>ibilut</i> ($n+1$) is equal to the number of non-zeros in the matrix <i>B</i> plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format section for more details..
<i>jbilut</i>	INTEGER. Array, its size is equal to the size of the array <i>bilut</i> . This array contains the column numbers for each non-zero element of the matrix <i>B</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format section for more details.
<i>ierr</i>	INTEGER. Error flag, informs about the routine completion.

Return Values

<i>ierr</i> =0	The routine completes the task normally.
<i>ierr</i> =-101	The routine is interrupted, the error occurs: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.
<i>ierr</i> =-102	The routine is interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as <i>ipar</i> (31)=0.
<i>ierr</i> =-103	The routine is interrupted, the error occurs: the element <i>ia</i> (<i>I</i> +1) is less than or equal to the element <i>ia</i> (<i>I</i>) (see Sparse Matrix Storage Format section).
<i>ierr</i> =-104	The routine is interrupted because the memory is insufficient for the internal work arrays.
<i>ierr</i> =-105	The routine is interrupted because the input value of <i>maxfil</i> is less than 0.
<i>ierr</i> =-106	The routine is interrupted because the size <i>n</i> of the input matrix is less than 0.
<i>ierr</i> =-107	The routine is interrupted, the error occurs: an element of the array <i>ja</i> is less than 0, or greater than <i>n</i> (see Sparse Matrix Storage Format section).

<code>ierr=101</code>	The value of <code>maxfil</code> is greater than or equal to <code>n</code> . The calculation is performed with the value of <code>maxfil</code> set to <code>(n-1)</code> .
<code>ierr=102</code>	The value of <code>tol</code> is less than 0. The calculation is performed with the value of the parameter set to <code>(-tol)</code> .
<code>ierr=103</code>	The absolute value of <code>tol</code> is greater than value of <code>dpar(31)</code> ; it can result in instability of the calculation.
<code>ierr=104</code>	The value of <code>dpar(31)</code> is equal to 0. It can cause the fail of the calculations.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilut (n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
INTEGER n, ierr, ipar(*), maxfil
INTEGER ia(*), ja(*), ibilut(*), jbilut(*)
DOUBLE PRECISION a(*), bilut(*), dpar(*), tol
```

C:

```
void dcsrilut (int *n, double *a, int *ia, int *ja, double *bilut, int *ibilut, int *jbilut,
double *tol, int *maxfil, int *ipar, double *dpar, int *ierr);
```

Calling Sparse Solver and Preconditioner Routines from C/C++

The calling interface for all of the Intel MKL sparse solver and preconditioner routines is designed to be used easily from FORTRAN 77 or Fortran 90. However, any of these routines can be invoked directly from C or C++ if users are familiar with the inter-language calling conventions of their platforms. These conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from Fortran to C/C++, and the platform specific method of decoration for Fortran external names.

To promote portability, the C header files provide a set of macros and type definitions intended to hide the inter-language calling conventions and provide an interface to the Intel MKL sparse solver routines that appears natural for C/C++.

For example, consider a hypothetical library routine `foo` that takes a real vector of length `n`, and returns an integer status. Fortran users would access such a function as:

```
INTEGER n, status, foo

REAL x(*)

status = foo(x, n)
```

As noted above, to invoke `foo`, C users need to know what C data types correspond to Fortran types `INTEGER` and `REAL`; what argument passing mechanism the Fortran compiler uses; and what, if any, name decoration the Fortran compiler performs when generating the external symbol `foo`.

However, by using the C specific header file, for example `mkl_solver.h`, the invocation of `foo`, within a C program would look as follows:

```
#include "mkl_solver.h"

_INTEGER_t i, status;

_REAL_t x[];

status = foo( x, i );
```

Note that in the above example, the header file `mkl_solver.h` provides definitions for the types `_INTEGER_t` and `_REAL_t` that correspond to the Fortran types `INTEGER` and `REAL`.

To simplify calling of the Intel MKL sparse solver routines from C and C++, the following approach of providing C definitions of Fortran types is used: if an argument or a result from a sparse solver is documented as having the Fortran language specific type `XXX`, then the C and C++ header files provide an appropriate C language type definitions for the name `_XXX_t`.

Caveat for C Users

One of the key differences between C/C++ and Fortran is the argument passing mechanisms for the languages: Fortran programs use pass-by-reference semantics and C/C++ programs use pass-by-value semantics. In the above example, the header file `mkl_solver.h` attempts to hide this difference, by defining a macro `foo`, which takes the address of the appropriate arguments. For example, on the Tru64 UNIX* operating system `mkl_solver.h` defines the macro as follows:

```
#define foo(a,b) foo_((a), &(b))
```

Note how constants are treated when using the macro form of `foo`. `foo(x, 10)` is converted into `foo_(x, &10)`. In a strictly ANSI compliant C compiler, taking the address of a constant is not permitted, so a strictly conforming program would look like:

```
INTEGER_t iTen = 10;

_REAL_t * x;

status = foo( x, iTen );
```

However, some C compilers in a non-ANSI compliant mode enable taking the address of a constant for ease of use with Fortran programs. The form `foo(x, 10)` is acceptable for such compilers.

Vector Mathematical Functions

This chapter describes Intel® MKL Vector Mathematical Functions Library (VML), which is designed to compute mathematical functions on vector arguments. VML is an integral part of Intel MKL and the VML terminology is used here for simplicity in discussing this group of functions.

VML includes a set of highly optimized implementations of certain computationally expensive core mathematical functions (power, trigonometric, exponential, hyperbolic etc.) that operate on vectors of real and complex numbers.

Application programs that might significantly improve performance with VML include nonlinear programming software, integrals computation, and many others.

VML functions are divided into the following groups according to the operations they perform:

- [VML Mathematical Functions](#) compute values of mathematical functions (such as sine, cosine, exponential, logarithm and so on) on vectors with unit increment indexing.
- [VML Pack/Unpack Functions](#) convert to and from vectors with positive increment indexing, vector indexing and mask indexing (see [Appendix B](#) for details on vector indexing methods).
- [VML Service Functions](#) allow the user to set/get the accuracy mode, and set/get the error code.

VML mathematical functions take an input vector as argument, compute values of the respective function element-wise, and return the results in an output vector.

All the Intel MKL VML functions are declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

Examples that demonstrate usage of the Vector Mathematical functions are available in the following directories:

```
${MKL}/examples/vmlc/source
```

```
${MKL}/examples/vmlf/source.
```

Data Types and Accuracy Modes

Mathematical and pack/unpack vector functions in VML have been implemented for vector arguments of single and double precision real data. Both Fortran- and C-interfaces to all functions, including VML service functions, are provided in the library. The differences in naming and calling the functions for Fortran- and C-interfaces are detailed in the [Function Naming Conventions](#) section below.

Each vector function from VML (for each data format) can work in three modes: High Accuracy (HA), Low Accuracy (LA), and Enhanced Performance (EP). For many functions, using the LA version improves performance at the cost of slight reduction in accuracy (1-2 least significant bits). In

contrast to the LA accuracy flavor, the EP flavor further enhances the performance at the cost of significant reduction in accuracy. In both single and double precision, about half bits of floating-point mantissa are correct. Moreover, subtle argument paths for certain functions (for example, large arguments in trigonometric functions) may be calculated with even less accuracy.

Despite the fact that default accuracy is HA, LA is more than sufficient in most cases. For certain applications that are not very demanding for accuracy (for example, media applications, some Monte Carlo simulations, etc.) you may find the EP accuracy flavor sufficient.

In addition, special value behavior may differ between the HA and LA versions of the functions. Any information on accuracy behavior can be found in the *Intel MKL Release Notes*.

Switching between the modes (HA, LA, EP) is accomplished by using `vmlSetMode(mode)` (see [Table 9-14](#)). The function `vmlGetMode()` returns the currently used mode. The High Accuracy mode is used by default.

Function Naming Conventions

Full names of all VML functions include only lowercase letters for Fortran interface, whereas for C interface names the lowercase letters are mixed with uppercase.

VML mathematical and pack/unpack function full names have the following structure:

`v<?><name><mod>`

The initial letter `v` is a prefix indicating that a function belongs to VML.

The `<?>` field is a precision prefix that indicates the data type:

<i>s</i>	REAL for Fortran interface, or <code>float</code> for C interface
<i>d</i>	DOUBLE PRECISION for Fortran interface, or <code>double</code> for C interface.
<i>c</i>	COMPLEX for Fortran interface, or <code>MKL_Complex8</code> for C interface.
<i>z</i>	DOUBLE COMPLEX for Fortran interface, or <code>MKL_Complex16</code> for C interface.

The `<name>` field indicates the function short name, with some of its letters in uppercase for C interface (see for example [Table 9-2](#) or [Table 9-13](#)).

The `<mod>` field (written in uppercase for C interface) is present in pack/unpack functions only; it indicates the indexing method used:

<i>i</i>	indexing with positive increment
<i>v</i>	indexing with index vector
<i>m</i>	indexing with mask vector.

VML service function full names have the following structure:

`vml<name>`

where `vml` is a prefix indicating that a function belongs to VML, and `<name>` is the function short name, which includes some uppercase letters for C interface (see [Table 9-13](#)). To call VML functions from an application program, use conventional function calls. For example, the VML exponential function for single precision real data can be called as

`call vsexp (n, a, y)` for Fortran interface, or
`vsExp (n, a, y);` for C interface.

Functions Interface

The interface to VML functions includes function full names and the arguments list. The Fortran- and C-interface descriptions for different groups of VML functions are given below. Note that some functions (`Div`, `Pow`, and `Atan2`) have two input vectors *a* and *b* as their arguments, while `SinCos` function has two output vectors *y* and *z*.

VML Mathematical Functions

Fortran:

```
call v<p><name>( n, a, y )
call v<p><name>( n, a, b, y )
call v<p><name>( n, a, y, z )
```

C:

```
v<p><name>( n, a, y );
v<p><name>( n, a, b, y );
v<p><name>( n, a, y, z );
```

Pack Functions

Fortran:

```
call v<p>packi( n, a, inca, y )
call v<p>packv( n, a, ia, y )
call v<p>packm( n, a, ma, y )
```

C:

```
v<p>PackI( n, a, inca, y );
```

```
v<p>PackV( n, a, ia, y );
v<p>PackM( n, a, ma, y );
```

Unpack Functions

Fortran:

```
call v<p>unpacki( n, a, y, incy )
call v<p>unpackv( n, a, y, iy )
call v<p>unpackm( n, a, y, my )
```

C:

```
v<p>UnpackI( n, a, y, incy );
v<p>UnpackV( n, a, y, iy );
v<p>UnpackM( n, a, y, my );
```

Service Functions

Fortran:

```
oldmode = vmlsetmode( mode )
mode = vmlgetmode( )
olderr = vmlseterrstatus ( err )
err = vmlgeterrstatus( )
olderr = vmlclearerrstatus( )
oldcallback = vmlseterrorcallback( callback )
callback = vmlgeterrorcallback( )
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldmode = vmlSetMode( mode );
mode = vmlGetMode( void );
olderr = vmlSetErrStatus ( err );
err = vmlGetErrStatus( void );
olderr = vmlClearErrStatus( void );
oldcallback = vmlSetErrorCallBack( callback );
callback = vmlGetErrorCallBack( void );
oldcallback = vmlClearErrorCallBack( void );
```

Input Parameters

<i>n</i>	number of elements to be calculated
<i>a</i>	first input vector
<i>b</i>	second input vector
<i>inca</i>	vector increment for the input vector <i>a</i>
<i>ia</i>	index vector for the input vector <i>a</i>
<i>ma</i>	mask vector for the input vector <i>a</i>
<i>incy</i>	vector increment for the output vector <i>y</i>
<i>iy</i>	index vector for the output vector <i>y</i>
<i>my</i>	mask vector for the output vector <i>y</i>
<i>err</i>	error code
<i>mode</i>	VML mode
<i>callback</i>	address of the callback function

Output Parameters

<i>y</i>	first output vector
<i>z</i>	second output vector
<i>err</i>	error code
<i>mode</i>	VML mode
<i>olderr</i>	former error code
<i>oldmode</i>	former VML mode
<i>callback</i>	address of the callback function
<i>oldcallback</i>	address of the former callback function

The data types of the parameters used in each function are specified in the respective function description section. All VML mathematical functions can perform in-place operations, which means that the same vector can be used as both input and output parameter. This holds true for functions with two input vectors as well, in which case one of them may be overwritten with the output vector. For functions with two output vectors, one of them may coincide with the input vector. But partially overlapping input and output vectors could lead to unpredictable results.

Vector Indexing Methods

Current VML mathematical functions work only with unit increment. Arrays with other increments, or more complicated indexing, can be accommodated by gathering the elements into a contiguous vector and then scattering them after the computation is complete.

Three following indexing methods are used to gather/scatter the vector elements in VML:

- positive increment
- index vector
- mask vector.

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the *<mod>* field in [Function Naming Conventions](#)). For more information on indexing methods see [Vector Arguments in VML](#) in Appendix B.

Error Diagnostics

The VML library has its own error handler. The only difference for C- and Fortran- interfaces is that the Intel MKL error reporting routine `XERBLA` can be called after the Fortran- interface VML function encounters an error, and this routine gets information on `VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM` input errors (see [Table 9-16](#)).

The VML error handler has the following properties:

- The Error Status (`vmErrStatus`) global variable is set after each VML function call. The possible values of this variable are shown in the [Table 9-16](#).
- Depending on the VML mode, the error handler function invokes:
 - `errno` variable setting. The possible values are shown in the [Table 9-1](#).
 - writing error text information to the `stderr` stream
 - raising the appropriate exception on error, if necessary
 - calling the additional error handler callback function.

Table 9-1. Set Values of the `errno` Variable

Value of <code>errno</code>	Description
0	No errors are detected.
<code>EINVAL</code>	The array dimension is not positive.
<code>EACCES</code>	NULL pointer is passed.

Value of <i>errno</i>	Description
<i>EDOM</i>	At least one of array values is out of a range of definition.
<i>ERANGE</i>	At least one of array values caused a singularity, overflow or underflow.

VML Mathematical Functions

This section describes VML functions which compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function group is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data both for Fortran- and C-interfaces, as well as a description of the input/output arguments.

For all VML mathematical functions, the input range of parameters is equal to the mathematical range of definition in the set of defined values for the respective data type. Several VML functions, specifically *Div*, *Exp*, *Sinh*, *Cosh*, and *Pow*, can result in an overflow. For these functions, the respective input threshold values that mark off the precision overflow are specified in the function description section. Note that in these specifications, *FLT_MAX* denotes the maximum number representable in single precision real data type, while *DBL_MAX* denotes the maximum number representable in double precision real data type.

Table 9-2 lists available mathematical functions and data types associated with them.

Table 9-2. VML Mathematical Functions

Function	Data Types	Description
Arithmetic Functions		
<i>v?Add</i>	<i>s, d, c, z</i>	Addition of the vector elements
<i>v?Sub</i>	<i>s, d, c, z</i>	Subtraction of the vector elements
<i>v?Sqr</i>	<i>s, d</i>	Squaring of the vector elements
<i>v?Mul</i>	<i>s, d, c, z</i>	Multiplication of the vector elements
<i>v?MulByConj</i>	<i>c, z</i>	Multiplication of elements of one vector by conjugated elements of the second vector
<i>v?Conj</i>	<i>c, z</i>	Conjugation of the vector elements
<i>v?Abs</i>	<i>s, d, c, z</i>	Absolute value of the vector elements
Power and Root Functions		
<i>v?Inv</i>	<i>s, d</i>	Inversion of the vector elements
<i>v?Div</i>	<i>s, d, c, z</i>	Divide elements of one vector by elements of second vector
<i>v?Sqrt</i>	<i>s, d, c, z</i>	Square root of vector elements
<i>v?InvSqrt</i>	<i>s, d</i>	Inverse square root of vector elements
<i>v?Cbrrt</i>	<i>s, d</i>	Cube root of vector elements

Function	Data Types	Description
v?InvCbrt	<i>s, d</i>	Inverse cube root of vector elements
v?Pow2o3	<i>s, d</i>	Each vector element raised to 2/3
v?Pow3o2	<i>s, d</i>	Each vector element raised to 3/2
v?Pow	<i>s, d, c, z</i>	Each vector element raised to the specified power
v?Powx	<i>s, d, c, z</i>	Each vector element raised to the constant power
v?Hypot	<i>s, d</i>	Square root of sum of squares
Exponential and Logarithmic Functions		
v?Exp	<i>s, d, c, z</i>	Exponential of vector elements
v?Expml	<i>s, d</i>	Exponential of vector elements decreased by 1
v?Ln	<i>s, d, c, z</i>	Natural logarithm of vector elements
v?Log10	<i>s, d, c, z</i>	Denary logarithm of vector elements
v?Log1p	<i>s, d</i>	Natural logarithm of vector elements that are increased by 1
Trigonometric Functions		
v?Cos	<i>s, d, c, z</i>	Cosine of vector elements
v?Sin	<i>s, d, c, z</i>	Sine of vector elements
v?SinCos	<i>s, d</i>	Sine and cosine of vector elements
v?CIS	<i>c, z</i>	Complex exponent of vector elements (cosine and sine combined to complex value)
v?Tan	<i>s, d, c, z</i>	Tangent of vector elements
v?Acos	<i>s, d, c, z</i>	Inverse cosine of vector elements
v?Asin	<i>s, d, c, z</i>	Inverse sine of vector elements
v?Atan	<i>s, d, c, z</i>	Inverse tangent of vector elements
v?Atan2	<i>s, d</i>	Four-quadrant inverse tangent of elements of two vectors
Hyperbolic Functions		
v?Cosh	<i>s, d, c, z</i>	Hyperbolic cosine of vector elements
v?Sinh	<i>s, d, c, z</i>	Hyperbolic sine of vector elements
v?Tanh	<i>s, d, c, z</i>	Hyperbolic tangent of vector elements
v?Acosh	<i>s, d, c, z</i>	Inverse hyperbolic cosine of vector elements
v?Asinh	<i>s, d, c, z</i>	Inverse hyperbolic sine of vector elements
v?Atanh	<i>s, d, c, z</i>	Inverse hyperbolic tangent of vector elements.
Special Functions		
v?Erf	<i>s, d</i>	Error function value of vector elements
v?Erfc	<i>s, d</i>	Complementary error function value of vector elements
v?CdfNorm	<i>s, d</i>	Cumulative normal distribution function value of vector elements
v?ErfInv	<i>s, d</i>	Inverse error function value of vector elements

Function	Data Types	Description
<code>v?ErfcInv</code>	s, d	Inverse complementary error function value of vector elements
<code>v?CdfNormInv</code>	s, d	Inverse cumulative normal distribution function value of vector elements
Rounding Functions		
<code>v?Floor</code>	s, d	Rounding towards minus infinity
<code>v?Ceil</code>	s, d	Rounding towards plus infinity
<code>v?Trunc</code>	s, d	Rounding towards zero infinity
<code>v?Round</code>	s, d	Rounding to nearest integer
<code>v?NearbyInt</code>	s, d	Rounding according to current mode
<code>v?Rint</code>	s, d	Rounding according to current mode and raising inexact result exception
<code>v?Modf</code>	s, d	Integer and fraction parts

Arithmetic Functions

v?Add

Performs element by element addition of vector a and vector b .

Syntax

Fortran:

```
call vsadd( n, a, b, y )
call vdadd( n, a, b, y )
call vcadd( n, a, b, y )
call vzadd( n, a, b, y )
```

C:

```
vsAdd( n, a, b, y );
vdAdd( n, a, b, y );
vcAdd( n, a, b, y );
vzAdd( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a, b	FORTRAN 77: REAL for vsadd DOUBLE PRECISION for vdadd COMPLEX for vcadd DOUBLE COMPLEX for vzadd Fortran 90: REAL, INTENT (IN) for vsadd DOUBLE PRECISION, INTENT (IN) for vdadd COMPLEX, INTENT (IN) for vcadd DOUBLE COMPLEX, INTENT (IN) for vzadd C: const float* for vsAdd const double* for vdAdd const MKL_Complex8* for vcAdd const MKL_Complex16* for vzAdd	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsadd DOUBLE PRECISION for vdadd	FORTRAN: Array, specifies the output vector y .

Name	Type	Description
	COMPLEX, for vcadd	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzadd	
	Fortran 90: REAL, INTENT(OUT) for vsadd	
	DOUBLE PRECISION, INTENT(OUT) for vdadd	
	COMPLEX, INTENT(OUT) for vcadd	
	DOUBLE COMPLEX, INTENT(OUT) for vzadd	
	C: float* for vsAdd	
	double* for vdAdd	
	MKL_Complex8* for vcAdd	
	MKL_Complex16* for vzAdd	

v?Sub

*Performs element by element subtraction of vector *b* from vector *a*.*

Syntax

Fortran:

```
call vssub( n, a, b, y )
call vdsup( n, a, b, y )
call vcsup( n, a, b, y )
call vzsub( n, a, b, y )
```

C:

```
vsSub( n, a, b, y );
vdSub( n, a, b, y );
vcSub( n, a, b, y );
vzSub( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vssub DOUBLE PRECISION for vdsub COMPLEX for vcsub DOUBLE COMPLEX for vzsub Fortran 90: REAL, INTENT (IN) for vssub DOUBLE PRECISION, INTENT (IN) for vdsub COMPLEX, INTENT (IN) for vcsub DOUBLE COMPLEX, INTENT (IN) for vzsub C: const float* for vsSub const double* for vdSub const MKL_Complex8* for vcSub const MKL_Complex16* for vz-Sub	FORTRAN: Arrays, specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vssub DOUBLE PRECISION for vdsup COMPLEX for vcsub DOUBLE COMPLEX for vzsub Fortran 90: REALINTENT (OUT) for vssub DOUBLE PRECISION, INTENT (OUT) for vdsup COMPLEX, INTENT (OUT) for vcsub DOUBLE COMPLEX, INTENT (OUT) for vzsub C: float* for vsSub double* for vdSub MKL_Complex8* for vcSub MKL_Complex16* for vzSub	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Sqr

*Performs element by element squaring of the
vector.*

Syntax

Fortran:

```
call vssqr( n, a, y )  
call vdsqr( n, a, y )
```

C:

```
vsSqr( n, a, y );
```

```
vdSqr( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vssqr DOUBLE PRECISION for vdsqr Fortran 90: REAL, INTENT (IN) for vssqr DOUBLE PRECISION, INTENT (IN) for vdsqr C: const float* for vsSqr const double* for vdSqr	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vssqr DOUBLE PRECISION for vdsqr Fortran 90: REAL, INTENT (OUT) for vssqr DOUBLE PRECISION, INTENT (OUT) for vdsqr	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	C: float* for vsSqr	
	double* for vdSqr	

v?Mul

Performs element by element multiplication of vector a and vector b .

Syntax

Fortran:

```
call vsmul( n, a, b, y )
call vdmul( n, a, b, y )
call vcmul( n, a, b, y )
call vzmul( n, a, b, y )
```

C:

```
vsMul( n, a, b, y );
vdMul( n, a, b, y );
vcMul( n, a, b, y );
vzMul( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
a, b	FORTRAN 77: REAL for vsmul DOUBLE PRECISION for vdmul	FORTRAN: Arrays, specify the input vectors a and b .

Name	Type	Description
	COMPLEX for vcmul	C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
	DOUBLE COMPLEX for vzmul	
	Fortran 90: REAL, INTENT (IN) for vsmul	
	DOUBLE PRECISION, INTENT (IN) for vdmul	
	COMPLEX, INTENT (IN) for vcmul	
	DOUBLE COMPLEX, INTENT (IN) for vzmul	
	C: const float* for vsMul	
	const double* for vdMul	
	const MKL_Complex8* for vcMul	
	const MKL_Complex16* for vz-Mul	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vsmul	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE PRECISION for vdmul	
	COMPLEX, for vcmul	
	DOUBLE COMPLEX for vzmul	
	Fortran 90: REAL, INTENT (OUT) for vsmul	
	DOUBLE PRECISION, INTENT (OUT) for vdmul	
	COMPLEX, INTENT (OUT) for vcmul	
	DOUBLE COMPLEX, INTENT (OUT) for vzmul	

Name	Type	Description
	C: float* for vsMul	
	double* for vdMul	
	MKL_Complex8* for vcMul	
	MKL_Complex16* for vzMul	

v?MulByConj

Performs element by element multiplication of vector a element and conjugated vector b element.

Syntax

Fortran:

```
call vcmulbyconj( n, a, b, y )
call vzmulbyconj( n, a, b, y )
```

C:

```
vcMulByConj( n, a, b, y );
vzMulByConj( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
a, b	FORTRAN 77: COMPLEX for vcmulbyconj DOUBLE COMPLEX for vzmulbyconj	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Name	Type	Description
	Fortran 90: COMPLEX, INTENT (IN) for vcmulbyconj DOUBLE COMPLEX, INTENT (IN) for vzmulbyconj C: const MKL_Complex8* for vcMulByConj const MKL_Complex16* for vz- MulByConj	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: COMPLEX for vcmul- byconj DOUBLE COMPLEX for vzmulby- conj Fortran 90: COMPLEX, INTENT (OUT) for vcmulbyconj DOUBLE COMPLEX, INTENT (OUT) for vzmulbyconj C: MKL_Complex8* for vcMulBy- Conj MKL_Complex16* for vzMulBy- Conj	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Conj

Performs element by element conjugation of the vector.

Syntax

Fortran:

```
call vcconj( n, a, y )  
call vzconj( n, a, y )
```

C:

```
vcConj( n, a, y );  
vzConj( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: COMPLEX, INTENT (IN) for vcconj DOUBLE COMPLEX, INTENT (IN) for vzconj Fortran 90: COMPLEX, INTENT (IN) for vcconj DOUBLE COMPLEX, INTENT (IN) for vzconj C: const MKL_Complex8* for vcConj	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex16* for vz-Conj	

Output Parameters

Name	Type	Description
<i>y</i>	<p>FORTRAN 77: COMPLEX, for vc-conj</p> <p>DOUBLE COMPLEX for vzconj</p> <p>Fortran 90: COMPLEX, INTENT (OUT) for vcconj</p> <p>DOUBLE COMPLEX, INTENT (OUT) for vzconj</p> <p>C: MKL_Complex8* for vcConj MKL_Complex16* for vzConj</p>	<p>FORTRAN: Array, specifies the output vector <i>y</i>.</p> <p>C: Pointer to an array that contains the output vector <i>y</i>.</p>

v?Abs

Computes absolute value of vector elements.

Syntax

Fortran:

```
call vsabs( n, a, y )
call vdabs( n, a, y )
call vcabs( n, a, y )
call vzabs( n, a, y )
```

C:

```
vsAbs( n, a, y );  
vdAbs( n, a, y );  
vcAbs( n, a, y );  
vzAbs( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsabs DOUBLE PRECISION for vdabs COMPLEX for vcabs DOUBLE COMPLEX for vzabs Fortran 90: REAL, INTENT (IN) for vsabs DOUBLE PRECISION, INTENT (IN) for vdabs COMPLEX, INTENT (IN) for vcabs DOUBLE COMPLEX, INTENT (IN) for vzabs C: const float* for vsAbs const double* for vdAbs const MKL_Complex8* for vcAbs const MKL_Complex16* for vz- Abs	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsabs, vcabs DOUBLE PRECISION for vdabs, vzabs Fortran 90: REAL, INTENT (OUT) for vsabs, vcabs DOUBLE PRECISION, INTENT (OUT) for vdabs, vzabs C: float* for vsAbs, vcAbs double* for vdAbs, vzAbs	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Power and Root Functions

v?Inv

Performs element by element inversion of the vector.

Syntax

Fortran:

```
call vsinv( n, a, y )
call vdiv( n, a, y )
```

C:

```
vsInv( n, a, y );
vdInv( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a	FORTTRAN 77: REAL for vs- inv DOUBLE PRECISION for vd- inv Fortran 90: REAL, INTENT (IN) for vsinv DOUBLE PRECISION, INTENT (IN) for vdiv C: const float* for vsInv const double* for vdInv	FORTTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
y	FORTTRAN 77: REAL for vsinv DOUBLE PRECISION for vdiv Fortran 90: REAL, INTENT (OUT) for vsinv DOUBLE PRECISION, INTENT (OUT) for vdiv C: float* for vsInv double* for vdInv	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

v?Div

Performs element by element division of vector a by vector b

Syntax

Fortran:

```
call vsdiv( n, a, b, y )
call vddiv( n, a, b, y )
call vcdiv( n, a, b, y )
call vzdiv( n, a, b, y )
```

C:

```
vsDiv( n, a, b, y );
vdDiv( n, a, b, y );
vcDiv( n, a, b, y );
vzDiv( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a, b	FORTRAN 77: REAL for vsdiv DOUBLE PRECISION for vddiv COMPLEX for vcdiv DOUBLE COMPLEX for vzdiv Fortran 90: REAL, INTENT (IN) for vsdiv	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Name	Type	Description
	DOUBLE PRECISION, INTENT (IN) for vddiv	
	COMPLEX, INTENT (IN) for vcdiv	
	DOUBLE COMPLEX, INTENT (IN) for vzdiv	
	C: const float* for vsDiv	
	const double* for vdDiv	
	const MKL_Complex8* for vcDiv	
	const MKL_Complex16* for vz- Div	

Table 9-3 Precision Overflow Thresholds for Div Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{FLT_MAX}$
double precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{DBL_MAX}$

NOTE. Overflow can occur also in Div complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsdiv DOUBLE PRECISION for vddiv COMPLEX for vcdiv DOUBLE COMPLEX for vzdiv Fortran 90: REAL, INTENT (OUT) for vsdiv DOUBLE PRECISION, INTENT (OUT) for vddiv	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	COMPLEX, INTENT(OUT) for vcdiv	
	DOUBLE COMPLEX, INTENT(OUT) for vzdiv	
	C: float* for vsDiv	
	double* for vdDiv	
	MKL_Complex8* for vcDiv	
	MKL_Complex16* for vzDiv	

v?Sqrt

Computes a square root of vector elements.

Syntax

Fortran:

```
call vssqrt( n, a, y )
call vdsqrt( n, a, y )
call vcsqrt( n, a, y )
call vzsqrt( n, a, y )
```

C:

```
vsSqrt( n, a, y );
vdSqrt( n, a, y );
vcSqrt( n, a, y );
vzSqrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vssqrt DOUBLE PRECISION for vdsqrt COMPLEX for vcsqrt DOUBLE COMPLEX for vzsqrt Fortran 90: REAL, INTENT (IN) for vssqrt DOUBLE PRECISION, INTENT (IN) for vdsqrt COMPLEX, INTENT (IN) for vcsqrt DOUBLE COMPLEX, INTENT (IN) for vzsqrt C: const float* for vsSqrt const double* for vdSqrt const MKL_Complex8* for vc- Sqrt const MKL_Complex16* for vzSqrt	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vssqrt DOUBLE PRECISION for vdsqrt	FORTTRAN: Array, specifies the output vector <i>y</i> .

Name	Type	Description
	COMPLEX for vcsqrt	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzsqrt	
	C: float* for vsSqrt	
	double* for vdSqrt	
	MKL_Complex8* for vcSqrt	
	MKL_Complex16* for vzSqrt	

v?InvSqrt

Computes an inverse square root of vector elements.

Syntax

Fortran:

```
call vsinvsqrt( n, a, y )
call vdinvsqrt( n, a, y )
```

C:

```
vsInvSqrt( n, a, y );
vdInvSqrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsin- vsqrt	FORTRAN: Array, specifies the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION for vdin-vsqrt	C: Pointer to an array that contains the input vector <i>a</i> .
	Fortran 90: REAL, INTENT(IN) for vsinvsqrt	
	DOUBLE PRECISION, INTENT(IN) for vdinvsqrt	
	C: const float* for vsInvSqrt const double* for vdInvSqrt	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsin-vsqrt	FORTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdin-vsqrt	C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT(OUT) for vsinvsqrt	
	DOUBLE PRECISION, INTENT(OUT) for vdinvsqrt	
	C: float* for vsInvSqrt double* for vdInvSqrt	

v?Cbrt

Computes a cube root of vector elements.

Syntax

Fortran:

```
call vsqrt( n, a, y )
call vdsqrt( n, a, y )
```

C:

```
vsqrt( n, a, y );
vdsqrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsqrt DOUBLE PRECISION for vdsqrt Fortran 90: REAL, INTENT (IN) for vsqrt DOUBLE PRECISION, INTENT (IN) for vdsqrt C: const float* for vsqrt const double* for vdsqrt	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for <code>vscbrt</code> DOUBLE PRECISION for <code>vdcbtrt</code> Fortran 90: REAL, INTENT (OUT) for <code>vscbrt</code> DOUBLE PRECISION, INTENT (OUT) for <code>vdcbtrt</code> C: float* for <code>vsCbtrt</code> double* for <code>vdCbtrt</code>	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?InvCbtrt

Computes an inverse cube root of vector elements.

Syntax

Fortran:

```
call vsinvcbrt( n, a, y )  
call vdinvcbrt( n, a, y )
```

C:

```
vsInvCbtrt( n, a, y );  
vdInvCbtrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	FORTTRAN 77: REAL for vsin-vcbrt DOUBLE PRECISION for vdin-vcbrt Fortran 90: REAL, INTENT (IN) for vsinvcbrt DOUBLE PRECISION, INTENT (IN) for vdinvcbrt C: const float* for vsInvCbrt const double* for vdInvCbrt	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vsin-vcbrt DOUBLE PRECISION for vdin-vcbrt Fortran 90: REAL, INTENT (OUT) for vsinvcbrt DOUBLE PRECISION, INTENT (OUT) for vdinvcbrt C: float* for vsInvCbrt double* for vdInvCbrt	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Pow2o3

Raises each element of a vector to the constant power 2/3.

Syntax

Fortran:

```
call vspow2o3( n, a, y )
call vdpow2o3( n, a, y )
```

C:

```
vsPow2o3( n, a, y );
vdPow2o3( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vspow2o3 DOUBLE PRECISION for vdpow2o3 Fortran 90: REAL, INTENT (IN) for vspow2o3 DOUBLE PRECISION, INTENT (IN) for vdpow2o3 C: const float* for vsPow2o3 const double* for vdPow2o3	FORTRAN: Arrays, specify the input vector <i>a</i> . C: Pointers to arrays that contain the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vspow2o3 DOUBLE PRECISION for vdpow2o3 Fortran 90: REAL, INTENT (OUT) for vspow2o3 DOUBLE PRECISION, INTENT (OUT) for vdpow2o3 C: float* for vsPow2o3 double* for vdPow2o3	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Pow3o2

Raises each element of a vector to the constant power 3/2.

Syntax

Fortran:

```
call vspow3o2( n, a, y )
call vdpow3o2( n, a, y )
```

C:

```
vsPow3o2( n, a, y );
vdPow3o2( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the number of elements to be calculated.

Name	Type	Description
	C: const int	
<i>a</i>	FORTRAN 77: REAL for vspow3o2 DOUBLE PRECISION for vdpow3o2 Fortran 90: REAL, INTENT (IN) for vspow3o2 DOUBLE PRECISION, INTENT (IN) for vdpow3o2 C: const float* for vsPow3o2 const double* for vdPow3o2	FORTRAN: Arrays, specify the input vector <i>a</i> . C: Pointers to arrays that contain the input vector <i>a</i> .

Table 9-4 Precision Overflow Thresholds for Pow3o2 Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT_MAX})^{2/3}$
double precision	$\text{abs}(a[i]) < (\text{DBL_MAX})^{2/3}$

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vspow3o2 DOUBLE PRECISION for vdpow3o2 Fortran 90: REAL, INTENT (OUT) for vspow3o2 DOUBLE PRECISION, INTENT (OUT) for vdpow3o2 C: float* for vsPow3o2 double* for vdPow3o2	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Pow

Computes a to the power b for elements of two vectors.

Syntax

Fortran:

```
call vspow( n, a, b, y )
call vdpow( n, a, b, y )
call vcpow( n, a, b, y )
call vzpow( n, a, b, y )
```

C:

```
vsPow( n, a, b, y );
vdPow( n, a, b, y );
vcPow( n, a, b, y );
vzPow( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vspow DOUBLE PRECISION for vdpow COMPLEX for vcpow DOUBLE COMPLEX for vzpow Fortran 90: REAL, INTENT (IN) for vspow	FORTRAN: Arrays, specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT (IN) for vdpow	
	COMPLEX, INTENT (IN) for vcpow	
	DOUBLE COMPLEX, INTENT (IN) for vzpow	
	C: const float* for vsPow	
	const double* for vdPow	
	const MKL_Complex8* for vcPow	
	const MKL_Complex16* for vzPow	

Table 9-5 Precision Overflow Thresholds for Pow Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT_MAX})^{1/b[i]}$
double precision	$\text{abs}(a[i]) < (\text{DBL_MAX})^{1/b[i]}$

NOTE. Overflow can occur also in Pow complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vspow DOUBLE PRECISION for vdpow COMPLEX for vcpow DOUBLE COMPLEX for vzpow Fortran 90: REAL, INTENT (OUT) for vspow DOUBLE PRECISION, INTENT (OUT) for vdpow	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	COMPLEX, INTENT(OUT) for vcpow	
	DOUBLE COMPLEX, INTENT(OUT) for vzpow	
	C: float* for vsPow	
	double* for vdPow	
	MKL_Complex8* for vcPow	
	MKL_Complex16* for vzPow	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The real function `Pow` has certain limitations on the input range of `a` and `b` parameters. Specifically, if `a[i]` is positive, then `b[i]` may be arbitrary. For negative `a[i]`, the value of `b[i]` must be integer (either positive or negative).

The complex function `Pow` has no such input range limitations.

v?Powx

Raises each element of a vector to the constant power.

Syntax

Fortran:

```
call vspowx( n, a, b, y )
call vdpowx( n, a, b, y )
call vcpowx( n, a, b, y )
call vzpowx( n, a, b, y )
```

C:

```
vsPowx( n, a, b, y );
vdPowx( n, a, b, y );
vcPowx( n, a, b, y );
vzPowx( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vspowx DOUBLE PRECISION for vdpowx COMPLEX for vcpowx DOUBLE COMPLEX for vzpowx Fortran 90: REAL, INTENT (IN) for vspowx DOUBLE PRECISION, INTENT (IN) for vdpowx COMPLEX, INTENT (IN) for vcpowx DOUBLE COMPLEX, INTENT (IN) for vzpowx C: const float* for vsPowx const double* for vdPowx const MKL_Complex8* for vcPowx const MKL_Complex16* for vzPowx	FORTRAN: Array <i>a</i> that specifies the input vector C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
b	FORTRAN 77: REAL for vspowx DOUBLE PRECISION for vdpowx COMPLEX for vcpowx DOUBLE COMPLEX for vzpowx Fortran 90: REAL, INTENT (IN) for vspowx DOUBLE PRECISION, INTENT (IN) for vdpowx COMPLEX, INTENT (IN) for vcpowx DOUBLE COMPLEX, INTENT (IN) for vzpowx C: const float for vsPowx const double for vdPowx const MKL_Complex8* for vcPowx const MKL_Complex16* for vzPowx	FORTRAN: Scalar value b that is the constant power. C: Constant value for power b .

Table 9-6 Precision Overflow Thresholds for Powx Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT_MAX})^{1/b}$
double precision	$\text{abs}(a[i]) < (\text{DBL_MAX})^{1/b}$

NOTE. Overflow can occur also in `Powx` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vspowx DOUBLE PRECISION for vdpowx COMPLEX for vcpowx DOUBLE COMPLEX for vzpowx Fortran 90: REAL, INTENT (OUT) for vspowx DOUBLE PRECISION, INTENT (OUT) for vdpowx COMPLEX, INTENT (OUT) for vcpowx DOUBLE COMPLEX, INTENT (OUT) for vzpowx C: float* for vsPowx double* for vdPowx MKL_Complex8* for vcPowx MKL_Complex16* for vzPowx	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The real function `Powx` has certain limitations on the input range of *a* and *b* parameters. Specifically, if *a*[*i*] is positive, then *b* may be arbitrary. For negative *a*[*i*], the value of *b* must be integer (either positive or negative).

The complex function `Powx` has no such input range limitations.

v?Hypot

Computes a square root of sum of two squared elements.

Syntax

Fortran:

```
call vshypot( n, a, b, y )
call vdhypot( n, a, b, y )
```

C:

```
vsHypot( n, a, b, y );
vdHypot( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of elements to be calculated.
<i>a,b</i>	FORTRAN 77: REAL for vshypot DOUBLE PRECISION for vdhypot Fortran 90: REAL, INTENT (IN) for vshypot DOUBLE PRECISION, INTENT (IN) for vdhypot C: const float* for vsHypot const double* for vdHypot	FORTRAN: Arrays that specify the input vectors <i>a</i> and <i>b</i> C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Table 9-7 Precision Overflow Thresholds for Hypot Function

Data Type	Threshold Limitations on Input Parameters
single precision	<code>abs(a[i]) < sqrt(FLT_MAX)</code>
	<code>abs(b[i]) < sqrt(FLT_MAX)</code>
double precision	<code>abs(a[i]) < sqrt(DBL_MAX)</code>
	<code>abs(b[i]) < sqrt(DBL_MAX)</code>

Output Parameters

Name	Type	Description
<code>y</code>	FORTRAN 77: REAL for <code>vshypot</code>	FORTRAN: Array, specifies the output vector <code>y</code> .
	DOUBLE PRECISION for <code>vdhypot</code>	
	Fortran 90: REAL, INTENT(OUT) for <code>vshypot</code>	C: Pointer to an array that contains the output vector <code>y</code> .
	DOUBLE PRECISION, INTENT(OUT) for <code>vdhypot</code>	
	C: float* for <code>vsHypot</code> double* for <code>vdHypot</code>	

Exponential and Logarithmic Functions

v?Exp

Computes an exponential of vector elements.

Syntax

Fortran:

```
call vsexp( n, a, y )
call vdexp( n, a, y )
call vcexp( n, a, y )
call vzexp( n, a, y )
```

C:

```
vsExp( n, a, y );
vdExp( n, a, y );
vcExp( n, a, y );
vzExp( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsexp DOUBLE PRECISION for vdexp COMPLEX for vcexp DOUBLE COMPLEX for vzexp	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (IN) for vsexp	
	DOUBLE PRECISION, INTENT (IN) for vdexp	
	COMPLEX, INTENT (IN) for vcexp	
	DOUBLE COMPLEX, INTENT (IN) for vzexp	
	C: const float* for vsExp	
	const double* for vdExp	
	const MKL_Complex8* for vcExp	
	const MKL_Complex16* for vz- Exp	

Table 9-8 Precision Overflow Thresholds for Exp Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL_MAX})$

NOTE. Overflow can occur also in `Exp` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTTRAN 77: REAL for vsexp DOUBLE PRECISION for vdexp COMPLEX for vcexp DOUBLE COMPLEX for vzexp Fortran 90: REAL, INTENT (OUT) for vsexp	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Name	Type	Description
	DOUBLE PRECISION, INTENT (OUT) for vdexp	
	COMPLEX, INTENT (OUT) for vcexp	
	DOUBLE COMPLEX, INTENT (OUT) for vzexp	
	C: float* for vsExp	
	double* for vdExp	
	MKL_Complex8* for vcExp	
	MKL_Complex16* for vzExp	

v?Expml

Computes an exponential of vector elements decreased by 1.

Syntax

Fortran:

```
call vsexpml( n, a, y )
call vdexpml( n, a, y )
```

C:

```
vsExpml( n, a, y );
vdExpml( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	FORTRAN 77: REAL for vsexpml DOUBLE PRECISION for vdexpml Fortran 90: REAL, INTENT(IN) for vsexpml DOUBLE PRECISION, INTENT(IN) for vdexpml C: const float* for vsExpml const double* for vdExpml	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Table 9-9 Precision Overflow Thresholds for Expml Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL_MAX})$

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsexpml DOUBLE PRECISION for vdexpml Fortran 90: REAL, INTENT(OUT) for vsexpml DOUBLE PRECISION, INTENT(OUT) for vdexpml C: float* for vsExpml double* for vdExpml	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Ln

Computes natural logarithm of vector elements.

Syntax

Fortran:

```
call vsln( n, a, y )
call vdlm( n, a, y )
call vcLn( n, a, y )
call vzLn( n, a, y )
```

C:

```
vsLn( n, a, y );
vdLn( n, a, y );
vcLn( n, a, y );
vzLn( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsln DOUBLE PRECISION for vdlm COMPLEX for vcLn DOUBLE COMPLEX for vzLn Fortran 90: REAL, INTENT (IN) for vsln	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT (IN) for vdlN	
	COMPLEX, INTENT (IN) for vcLn	
	DOUBLE COMPLEX, INTENT (IN) for vzLn	
	C: const float* for vsLn	
	const double* for vdLn	
	const MKL_Complex8* for vcLn	
	const MKL_Complex16* for vzLn	

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsLn DOUBLE PRECISION for vdlN COMPLEX for vcLn DOUBLE COMPLEX for vzLn	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT (OUT) for vsLn DOUBLE PRECISION, INTENT (OUT) for vdlN COMPLEX, INTENT (OUT) for vcLn DOUBLE COMPLEX, INTENT (OUT) for vzLn	
	C: float* for vsLn double* for vdLn MKL_Complex8* for vcLn MKL_Complex16* for vzLn	

v?Log10

Computes denary logarithm of vector elements.

Syntax

Fortran:

```
call vslog10( n, a, y )
call vdlog10( n, a, y )
call vclog10( n, a, y )
call vzlog10( n, a, y )
```

C:

```
vsLog10( n, a, y );
vdLog10( n, a, y );
vcLog10( n, a, y );
vzLog10( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vslog10 DOUBLE PRECISION for vdlog10 COMPLEX for vclog10 DOUBLE COMPLEX for vzlog10 Fortran 90: REAL, INTENT (IN) for vslog10	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdlog10	
	COMPLEX, INTENT(IN) for vclog10	
	DOUBLE COMPLEX, INTENT(IN) for vzlog10	
	C: const float* for vsLog10 const double* for vdLog10 const MKL_Complex8* for vcLog10 const MKL_Complex16* for vzLog10	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vslog10 DOUBLE PRECISION for vdlog10 COMPLEX for vclog10 DOUBLE COMPLEX for vzlog10	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT(OUT) for vslog10 DOUBLE PRECISION, INTENT(OUT) for vdlog10 COMPLEX, INTENT(OUT) for vclog10 DOUBLE COMPLEX, INTENT(OUT) for vzlog10	
	C: float* for vsLog10	

Name	Type	Description
	double* for vdLog10	
	MKL_Complex8* for vcLog10	
	MKL_Complex16* for vzLog10	

v?Log1p

Computes natural logarithm of vector elements that are increased by 1.

Syntax

Fortran:

```
call vslog1p( n, a, y )
call vdlog1p( n, a, y )
```

C:

```
vsLog1p( n, a, y );
vdLog1p( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vslog1p DOUBLE PRECISION for vdlog1p Fortran 90: REAL, INTENT (IN) for vslog1p	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdloglp	
	C: const float* for vsLoglp const double* for vdLoglp	

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsloglp DOUBLE PRECISION for vdloglp Fortran 90: REAL, INTENT(OUT) for vsloglp DOUBLE PRECISION, INTENT(OUT) for vdloglp C: float* for vsLoglp double* for vdLoglp	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Trigonometric Functions

v?Cos

Computes cosine of vector elements.

Syntax

Fortran:

```
call vscos( n, a, y )  
call vdcos( n, a, y )  
call vccos( n, a, y )  
call vzcoss( n, a, y )
```

C:

```
vsCos( n, a, y );
vdCos( n, a, y );
vcCos( n, a, y );
vzCos( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsCos DOUBLE PRECISION for vdcos COMPLEX for vcCos DOUBLE PRECISION for vzCos Fortran 90: REAL, INTENT (IN) for vsCos DOUBLE PRECISION, INTENT (IN) for vdcos COMPLEX, INTENT (IN) for vcCos DOUBLE PRECISION, INTENT (IN) for vzCos C: const float* for vsCos const double* for vdCos const MKL_Complex8* for vcCos const MKL_Complex16* for vzCos	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for <i>vscos</i> DOUBLE PRECISION for <i>vdcos</i> COMPLEX for <i>vccos</i> DOUBLE COMPLEX for <i>vzcos</i> Fortran 90: REAL, INTENT (OUT) for <i>vscos</i> DOUBLE PRECISION, INTENT (OUT) for <i>vdcos</i> COMPLEX, INTENT (OUT) for <i>vccos</i> DOUBLE COMPLEX, INTENT (OUT) for <i>vzcos</i> C: float* for <i>vsCos</i> double* for <i>vdCos</i> MKL_Complex8* for <i>vcCos</i> MKL_Complex16* for <i>vzCos</i>	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

v?Sin

Computes sine of vector elements.

Syntax

Fortran:

```
call vssin( n, a, y )
call vdsin( n, a, y )
call vcsin( n, a, y )
call vzsine( n, a, y )
```

C:

```
vsSin( n, a, y );
vdSin( n, a, y );
vcSin( n, a, y );
vzSin( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vssin DOUBLE PRECISION for vdsin COMPLEX for vcsin DOUBLE PRECISION for vzsine Fortran 90: REAL, INTENT (IN) for vssin	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdsin	
	COMPLEX, INTENT(IN) for vcsin	
	DOUBLE PRECISION, INTENT(IN) for vzsine	
	C: const float* for vsSin	
	const double* for vdSin	
	const MKL_Complex8* for vcSin	
	const MKL_Complex16* for vzSin	

Output Parameters

Name	Type	Description
y	FORTTRAN 77: REAL for vssin DOUBLE PRECISION for vdsin COMPLEX for vcsin DOUBLE COMPLEX for vzsine	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT(OUT) for vssin DOUBLE PRECISION, INTENT(OUT) for vdsin COMPLEX, INTENT(OUT) for vcsin DOUBLE COMPLEX, INTENT(OUT) for vzsine C: float* for vsSin double* for vdSin MKL_Complex8* for vcSin	

Name	Type	Description
	MKL_Complex16* for vzSin	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

v?SinCos

Computes sine and cosine of vector elements.

Syntax

Fortran:

```
call vssincos( n, a, y, z )
```

```
call vdsincos( n, a, y, z )
```

C:

```
vsSinCos( n, a, y, z );
```

```
vdSinCos( n, a, y, z );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the number of elements to be calculated.

Name	Type	Description
	C: const int	
<i>a</i>	FORTRAN 77: REAL for vssincos DOUBLE PRECISION for vdsincos Fortran 90: REAL, INTENT (IN) for vssincos DOUBLE PRECISION, INTENT (IN) for vdsincos C: const float* for vsSinCos const double* for vdSinCos	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y, z</i>	FORTRAN 77: REAL for vssincos DOUBLE PRECISION for vdsincos Fortran 90: REAL, INTENT (OUT) for vssincos DOUBLE PRECISION, INTENT (OUT) for vdsincos C: float* for vsSinCos double* for vdSinCos	FORTRAN: Arrays, specify the output vectors <i>y</i> (for sine values) and <i>z</i> (for cosine values). C: Pointers to arrays that contain the output vectors <i>y</i> (for sinevalues) and <i>z</i> (for cosine values).

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that

do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

v?CIS

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

Fortran:

```
call vccis( n, a, y )
call vzcis( n, a, y )
```

C:

```
vcCIS( n, a, y );
vzCIS( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vccis DOUBLE PRECISION for vzcis Fortran 90: REAL, INTENT (IN) for vccis DOUBLE PRECISION, INTENT (IN) for vzcis C: const float* for vcCIS	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vzCIS	

Output Parameters

Name	Type	Description
y	FORTRAN 77: COMPLEX for vccis DOUBLE COMPLEX for vzcis Fortran 90: COMPLEX, INTENT(OUT) for vccis DOUBLE COMPLEX, INTENT(OUT) for vzcis C: MKL_Complex8* for vcCIS MKL_Complex16* for vzCIS	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Tan

Computes tangent of vector elements.

Syntax

Fortran:

```
call vstan( n, a, y )
call vdtan( n, a, y )
call vctan( n, a, y )
call vztan( n, a, y )
```

C:

```
vsTan( n, a, y );
vdTan( n, a, y );
vcTan( n, a, y );
vzTan( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL, INTENT (IN) for vstan DOUBLE PRECISION, INTENT (IN) for vdtan COMPLEX, INTENT (IN) for vctan DOUBLE COMPLEX, INTENT (IN) for vztan Fortran 90: REAL, INTENT (IN) for vstan DOUBLE PRECISION, INTENT (IN) for vdtan COMPLEX, INTENT (IN) for vctan DOUBLE COMPLEX, INTENT (IN) for vztan C: const float* for vsTan const double* for vdTan const MKL_Complex8* for vcTan const MKL_Complex16* for vz-Tan	FORTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for <i>vstan</i> DOUBLE PRECISION for <i>vdtan</i> COMPLEX for <i>vctan</i> DOUBLE COMPLEX for <i>vztan</i> Fortran 90: REAL, INTENT (OUT) for <i>vstan</i> DOUBLE PRECISION, INTENT (OUT) for <i>vdtan</i> COMPLEX, INTENT (OUT) for <i>vctan</i> DOUBLE COMPLEX, INTENT (OUT) for <i>vztan</i> C: float* for <i>vsTan</i> double* for <i>vdTan</i> MKL_Complex8* for <i>vcTan</i> MKL_Complex16* for <i>vzTan</i>	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

v?Acos

Computes inverse cosine of vector elements.

Syntax

Fortran:

```
call vsacos( n, a, y )
call vdacos( n, a, y )
call vcacos( n, a, y )
call vzacos( n, a, y )
```

C:

```
vsAcos( n, a, y );
vdAcos( n, a, y );
vcAcos( n, a, y );
vzAcos( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsacos DOUBLE PRECISION for vdacos COMPLEX for vcacos DOUBLE COMPLEX for vzacos Fortran 90: REAL, INTENT (IN) for vsacos	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT (IN) for vdacos	
	COMPLEX, INTENT (IN) for vcacos	
	DOUBLE COMPLEX, INTENT (IN) for vzaeos	
	C: const float* for vsAcos	
	const double* for vdAcos	
	const MKL_Complex8* for vca-	
	cos	
	const MKL_Complex16* for vza-	
	cos	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vsacos	FORTTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdacos	
	COMPLEX for vcacos	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzaeos	
	Fortran 90: REAL, INTENT (OUT) for vsacos	
	DOUBLE PRECISION, INTENT (OUT) for vdacos	
	COMPLEX, INTENT (OUT) for vca-	
	cos	
	DOUBLE COMPLEX, INTENT (OUT) for vzaeos	
	C: float* for vsAcos	
	double* for vdAcos	

Name	Type	Description
	MKL_Complex8* for vcAcos	
	MKL_Complex16* for vzAcos	

v?Asin

Computes inverse sine of vector elements.

Syntax

Fortran:

```
call vsasin( n, a, y )
call vdasin( n, a, y )
call vcasin( n, a, y )
call vzasin( n, a, y )
```

C:

```
vsAsin( n, a, y );
vdAsin( n, a, y );
vcAsin( n, a, y );
vzAsin( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vsasin DOUBLE PRECISION for vdasin	FORTTRAN: Array, specifies the input vector <i>a</i> .

Name	Type	Description
	COMPLEX for vcasin	C: Pointer to an array that contains the input vector <i>a</i> .
	DOUBLE COMPLEX for vzasin	
	Fortran 90: REAL, INTENT(IN) for vsasin	
	DOUBLE PRECISION, INTENT(IN) for vdasin	
	COMPLEX, INTENT(IN) for vcasin	
	DOUBLE COMPLEX, INTENT(IN) for vzasin	
	C: const float* for vsAsin	
	const double* for vdAsin	
	const MKL_Complex8* for vcAsin	
	const MKL_Complex16* for vzAsin	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vsasin	FORTTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdasin	
	COMPLEX for vcasin	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzasin	
	Fortran 90: REAL, INTENT(OUT) for vsasin	
	DOUBLE PRECISION, INTENT(OUT) for vdasin	
	COMPLEX, INTENT(OUT) for vcasin	

Name	Type	Description
	DOUBLE COMPLEX, INTENT (OUT) for vzasin	
	C: float* for vsAsin	
	double* for vdAsin	
	MKL_Complex8* for vcAsin	
	MKL_Complex16* for vzAsin	

v?Atan

Computes inverse tangent of vector elements.

Syntax

Fortran:

```
call vsatan( n, a, y )
call vdatan( n, a, y )
call vcatan( n, a, y )
call vzatan( n, a, y )
```

C:

```
vsAtan( n, a, y );
vdAtan( n, a, y );
vcAtan( n, a, y );
vzAtan( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the number of elements to be calculated.

Name	Type	Description
	C: const int	
a	FORTRAN 77: REAL for vsatan	FORTRAN: Array, specifies the input vector <i>a</i> .
	DOUBLE PRECISION for vdatan	
	COMPLEX for vcatan	C: Pointer to an array that contains the input vector <i>a</i> .
	DOUBLE COMPLEX for vzatan	
	Fortran 90: REAL, INTENT (IN) for vsatan	
	DOUBLE PRECISION, INTENT (IN) for vdatan	
	COMPLEX, INTENT (IN) for vcatan	
	DOUBLE COMPLEX, INTENT (IN) for vzatan	
	C: const float* for vsAtan	
	const double* for vdAsin	
	const MKL_Complex8* for vcAtan	
	const MKL_Complex16* for vzAsin	

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsatan	FORTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdatan	
	COMPLEX for vcatan	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzatan	
	Fortran 90: REAL, INTENT (OUT) for vsatan	

Name	Type	Description
	DOUBLE PRECISION, INTENT (OUT) for vdatan	
	COMPLEX, INTENT (OUT) for vcatan	
	DOUBLE COMPLEX, INTENT (OUT) for vzatan	
	C: float* for vsAtan	
	double* for vdAtan	
	MKL_Complex8* for vcAtan	
	MKL_Complex16* for vzAtan	

v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

Fortran:

```
call vsatan2( n, a, b, y )
call vdatan2( n, a, b, y )
```

C:

```
vsAtan2( n, a, b, y );
vdAtan2( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the number of elements to be calculated.

Name	Type	Description
	C: <code>const int</code>	
a, b	FORTRAN 77: <code>REAL</code> for <code>vsatan2</code> <code>DOUBLE PRECISION</code> for <code>vdatan2</code> Fortran 90: <code>REAL, INTENT (IN)</code> for <code>vsatan2</code> <code>DOUBLE PRECISION, INTENT (IN)</code> for <code>vdatan2</code> C: <code>const float*</code> for <code>vsAtan2</code> <code>const double*</code> for <code>vdAtan2</code>	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Output Parameters

Name	Type	Description
y	FORTRAN 77: <code>REAL</code> for <code>vsatan2</code> <code>DOUBLE PRECISION</code> for <code>vdatan2</code> Fortran 90: <code>REAL, INTENT (OUT)</code> for <code>vsatan2</code> <code>DOUBLE PRECISION, INTENT (OUT)</code> for <code>vdatan2</code> C: <code>float*</code> for <code>vsAtan2</code> <code>double*</code> for <code>vdAtan2</code>	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector y are computed as the four-quadrant arctangent of $a[i] / b[i]$.

Hyperbolic Functions

v?Cosh

Computes hyperbolic cosine of vector elements.

Syntax

Fortran:

```
call vscosh( n, a, y )
call vdcosh( n, a, y )
call vccosh( n, a, y )
call vzcosh( n, a, y )
```

C:

```
vsCosh( n, a, y );
vdCosh( n, a, y );
vcCosh( n, a, y );
vzCosh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vscosh DOUBLE PRECISION for vdcosh COMPLEX for vccosh DOUBLE COMPLEX for vzcosh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (IN) for vscosh	
	DOUBLE PRECISION, INTENT (IN) for vdcosh	
	COMPLEX, INTENT (IN) for vccosh	
	DOUBLE COMPLEX, INTENT (IN) for vzcosh	
	C: const float* for vsCosh const double* for vdCosh const MKL_Complex8* for vc- Cosh const MKL_Complex16* for vz- Cosh	

Table 9-10 Precision Overflow Thresholds for Cosh Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT_MAX}) - \ln 2 < a[i] < \ln(\text{FLT_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL_MAX}) - \ln 2 < a[i] < \ln(\text{DBL_MAX}) + \ln 2$

NOTE. Overflow can occur also in Cosh complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vscosh DOUBLE PRECISION for vdcosh COMPLEX for vccosh DOUBLE COMPLEX for vzcosh	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Name	Type	Description
	Fortran 90: REAL, INTENT (OUT) for vscosh	
	DOUBLE PRECISION, INTENT (OUT) for vdcosh	
	COMPLEX, INTENT (OUT) for vc- cosh	
	DOUBLE COMPLEX, INTENT (OUT) for vzcosh	
	C: float* for vsCosh	
	double* for vdCosh	
	MKL_Complex8* for vcCosh	
	MKL_Complex16* for vzCosh	

v?Sinh

Computes hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vssinh( n, a, y )
call vdsinh( n, a, y )
call vcsinh( n, a, y )
call vzsinh( n, a, y )
```

C:

```
vsSinh( n, a, y );
vdSinh( n, a, y );
vcSinh( n, a, y );
vzSinh( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vssinh DOUBLE PRECISION for vdsinh COMPLEX for vcsinh DOUBLE COMPLEX for vzsinh Fortran 90: REAL, INTENT (IN) for vssinh DOUBLE PRECISION, INTENT (IN) for vdsinh COMPLEX, INTENT (IN) for vcsinh DOUBLE COMPLEX, INTENT (IN) for vzsinh C: const float* for vsSinh const double* for vdSinh const MKL_Complex8* for vc- Sinh const MKL_Complex16* for vzS- inh	FORTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Table 9-11 Precision Overflow Thresholds for Sinh Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT_MAX}) - \ln 2 < a[i] < \ln(\text{FLT_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL_MAX}) - \ln 2 < a[i] < \ln(\text{DBL_MAX}) + \ln 2$

NOTE. Overflow can occur also in Sinh complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vssinh DOUBLE PRECISION for vdsinh COMPLEX for vcsinh DOUBLE COMPLEX for vzsinh Fortran 90: REAL, INTENT (OUT) for vssinh DOUBLE PRECISION, INTENT (OUT) for vdsinh COMPLEX, INTENT (OUT) for vc-sinh DOUBLE COMPLEX, INTENT (OUT) for vzsinh C: float* for vsSinh double* for vdSinh MKL_Complex8* for vcSinh MKL_Complex16* for vzSinh	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Tanh

Computes hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vstanh( n, a, y )
call vdtanh( n, a, y )
call vctanh( n, a, y )
call vztanh( n, a, y )
```

C:

```
vsTanh( n, a, y );
vdTanh( n, a, y );
vcTanh( n, a, y );
vzTanh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vstanh DOUBLE PRECISION for vdtanh COMPLEX for vctanh DOUBLE COMPLEX for vztanh Fortran 90: REAL, INTENT(IN) for vstanh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vstanh DOUBLE PRECISION for vdtanh COMPLEX for cstanh DOUBLE COMPLEX for zdtanh Fortran 90: REAL, INTENT(OUT) for vstanh DOUBLE PRECISION, INTENT(OUT) for vdtanh COMPLEX, INTENT(OUT) for cstanh DOUBLE COMPLEX, INTENT(OUT) for zdtanh C: float* for vsTanh double* for vdTanh	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	MKL_Complex8* for vcTanh	
	MKL_Complex16* for vzTanh	

v?Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

Fortran:

```
call vsacosh( n, a, y )
call vdacosh( n, a, y )
call vcacosh( n, a, y )
call vzacosh( n, a, y )
```

C:

```
vsAcosh( n, a, y );
vdAcosh( n, a, y );
vcAcosh( n, a, y );
vzAcosh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsacosh DOUBLE PRECISION for vdacosh	FORTRAN: Array, specifies the input vector <i>a</i> .

Name	Type	Description
	COMPLEX for vcacosh	C: Pointer to an array that contains the input vector <i>a</i> .
	DOUBLE COMPLEX for vzacosh

	C: float* for vsAcosh	
	double* for vdAcosh	
	MKL_Complex8* for vcAcosh	
	MKL_Complex16* for vzAcosh	

v?Asinh

Computes inverse hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vsasinh( n, a, y )
call vdasinh( n, a, y )
call vcasinh( n, a, y )
call vzasinh( n, a, y )
```

C:

```
vsAsinh( n, a, y );
vdAsinh( n, a, y );
vcAsinh( n, a, y );
vzAsinh( n, a, y );
```

Input Parameters

Name	Type	Description

	MKL_Complex16* for vzAtanh	

Special Functions

v?Erf

Computes the error function value of vector elements.

Syntax

Fortran:

```
call vserf( n, a, y )
call vderf( n, a, y )
```

C:

```
vsErf( n, a, y );
vdErf( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserf DOUBLE PRECISION for vderf	FORTRAN: Array, specifies the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT(IN) for <code>vserf</code>	C: Pointer to an array that contains the input vector <i>a</i> .
	DOUBLE PRECISION, INTENT(IN) for <code>vderf</code>	
	C: <code>const float*</code> for <code>vsErf</code> <code>const double*</code> for <code>vdErf</code>	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for <code>vserf</code> DOUBLE PRECISION for <code>vderf</code>	FORTTRAN: Array, specifies the output vector <i>y</i> .
	Fortran 90: REAL, INTENT(OUT) for <code>vserf</code>	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE PRECISION, INTENT(OUT) for <code>vderf</code>	
	C: <code>float*</code> for <code>vsErf</code> <code>double*</code> for <code>vdErf</code>	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `Erf` computes the error function values for elements of the input vector *a* and writes them to the output vector *y*.

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

1. $\text{erfc}(x) = 1 - \text{erf}(x),$

where erfc is the complementary error function.

2. $\Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1),$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

Figure 9-1 illustrates the relationships among Erf family functions (Erf, Erfc, CdfNorm).

Figure 9-1 Erf Family Functions Relationship

Useful relations for these functions:

$$\text{erf}(x) + \text{erfc}(x) = 1$$

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$$

v?Erfc

Computes the complementary error function value of vector elements.

Syntax

Fortran:

```
call vserfc( n, a, y )
call vderfc( n, a, y )
```

C:

```
vsErfc( n, a, y );
vdErfc( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserfc DOUBLE PRECISION for vderfc Fortran 90: REAL, INTENT (IN) for vserfc DOUBLE PRECISION, INTENT (IN) for vderfc C: const float* for vsErfc	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	<code>const double*</code> for <code>vdErfc</code>	

Output Parameters

Name	Type	Description
<code>y</code>	FORTRAN 77: <code>REAL</code> for <code>vserfc</code> <code>DOUBLE PRECISION</code> for <code>vderfc</code> Fortran 90: <code>REAL, INTENT(OUT)</code> for <code>vserfc</code> <code>DOUBLE PRECISION, INTENT(OUT)</code> for <code>vderfc</code> C: <code>float*</code> for <code>vsErfc</code> <code>double*</code> for <code>vdErfc</code>	FORTRAN: Array, specifies the output vector <code>y</code> . C: Pointer to an array that contains the output vector <code>y</code> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `Erfc` computes the complementary error function values for elements of the input vector `a` and writes them to the output vector `y`.

The complementary error function is defined as given by:

$$\text{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

1. $\text{erfc}(x) = 1 - \text{erf}(x)$.

$$2. \Phi(x) = \frac{1}{2} \operatorname{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

See also [Figure 9-1](#) in `Erf` function description for `Erfc` function relationship with the other functions of `Erf` family.

v?CdfNorm

Computes the cumulative normal distribution function values of vector elements.

Syntax

Fortran:

```
call vscdfnorm( n, a, y )
call vdcdfnorm( n, a, y )
```

C:

```
vsCdfNorm( n, a, y );
vdCdfNorm( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vscdfnorm DOUBLE PRECISION for vd-cdfnorm Fortran 90: REAL, INTENT (IN) for vscdfnorm DOUBLE PRECISION, INTENT (IN) for vdcdfnorm C: const float* for vsCdfNorm const double* for vdCdfNorm	FORTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vscdfnorm DOUBLE PRECISION for vd-cdfnorm Fortran 90: REAL, INTENT (OUT) for vscdfnorm DOUBLE PRECISION, INTENT (OUT) for vdcdfnorm C: float* for vsCdfNorm double* for vdCdfNorm	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `CdfNorm` computes the cumulative normal distribution function values for elements of the input vector `a` and writes them to the output vector `y`.

The cumulative normal distribution function is defined as given by:

$$\text{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt .$$

Useful relations:

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$$

where `Erf` and `Erfc` are the error and complementary error functions.

See also [Figure 9-1](#) in `Erf` function description for `CdfNorm` function relationship with the other functions of `Erf` family.

v?ErfInv

Computes inverse error function value of vector elements.

Syntax

Fortran:

```
call vserfinv( n, a, y )
call vderfinv( n, a, y )
```

C:

```
vsErfInv( n, a, y );  
vdErfInv( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserfinv DOUBLE PRECISION for vderfinv Fortran 90: REAL, INTENT (IN) for vserfinv DOUBLE PRECISION, INTENT (IN) for vderfinv C: const float* for vsErfInv const double* for vdErfInv	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vserfinv DOUBLE PRECISION for vderfinv Fortran 90: REAL, INTENT (OUT) for vserfinv DOUBLE PRECISION, INTENT (OUT) for vderfinv C: float* for vsErfInv	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
------	------	-------------

	double* for vdErfInv	
--	----------------------	--

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function `ErfInv` computes the inverse error function values for elements of the input vector a and writes them to the output vector y

$$y = \text{erf}^{-1}(a),$$

where $\text{erf}(x)$ is the error function defined as given by:

$$\text{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

$$1. \quad \text{erf}^{-1}(x) = \text{erfc}^{-1}(1 - x),$$

where erfc is the complementary error function.

$$2. \quad \Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \quad \Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

Figure 9-2 illustrates the relationships among `ErfInv` family functions (`ErfInv`, `ErfcInv`, `CdfNormInv`).

Figure 9-2 ErfInv Family Functions Relationship

Useful relations for these functions:

$$\text{erfcInv}(x) = \text{erfInv}(1 - x)$$

$$\text{cdfnormInv}(x) = \sqrt{2} \text{erfInv}(2x - 1) = \sqrt{2} \text{erfcInv}(2 - 2x)$$

See Also

- [Special Functions](#)

- `ErfcInv` Computes the inverse complementary error function value of vector elements.
- `CdfNormInv` Computes the inverse cumulative normal distribution function values of vector elements.

v?ErfcInv

Computes the inverse complementary error function value of vector elements.

Syntax

Fortran:

```
call vserfcinv( n, a, y )
call vderfcinv( n, a, y )
```

C:

```
vsErfcInv( n, a, y );
vdErfcInv( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserfcinv DOUBLE PRECISION for vderfcinv Fortran 90: REAL, INTENT(IN) for vserfcinv	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vderfcinv	
	C: const float* for vsErfcInv const double* for vdErfcInv	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vserfcinv DOUBLE PRECISION for vderfcinv Fortran 90: REAL, INTENT(OUT) for vserfcinv DOUBLE PRECISION, INTENT(OUT) for vderfcinv C: float* for vsErfcInv double* for vdErfcInv	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `ErfcInv` computes the inverse complimentary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse complimentary error function is defined as given by:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\text{erfinv}(x) = \text{erf}^{-1}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt,$$

where `erf(x)` denotes the error function and `erfinv(x)` denotes the inverse error function.
See also [Figure 9-2](#) in `ErfInv` function description for `ErfcInv` function relationship with the other functions of `ErfInv` family.

v?CdfNormInv

Computes the inverse cumulative normal distribution function values of vector elements.

Syntax

Fortran:

```
call vscdfnorminv( n, a, y )
call vdcdfnorminv( n, a, y )
```

C:

```
vsCdfNormInv( n, a, y );
vdCdfNormInv( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vscdfnorminv DOUBLE PRECISION for vdcdfnorminv	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (IN) for vscdfnorminv	
	DOUBLE PRECISION, INTENT (IN) for vdcdfnorminv	
	C: const float* for vsCdfNormInv	
	const double* for vd- CdfNormInv	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vscdfnorm	FORTTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vd- cdfnorminv	C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT (OUT) for vscdfnorm	
	DOUBLE PRECISION, INTENT (OUT) for vdcdfnorminv	
	C: float* for vsCdfNormInv	
	double* for vdCdfNormInv	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `CdfNormInv` computes the inverse cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse cumulative normal distribution function is defined as given by:

$$\text{CdfNormInv}(x) = \text{CdfNorm}^{-1}(x) ,$$

where $\text{CdfNorm}(x)$ denotes the cumulative normal distribution function.

Useful relations:

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

where $\text{erfinv}(x)$ denotes the inverse error function and $\text{erfcinv}(x)$ denotes the inverse complementary error functions.

See also [Figure 9-2](#) in `ErfInv` function description for `CdfNormInv` function relationship with the other functions of `ErfInv` family.

Rounding Functions

v?Floor

Computes a rounded towards minus infinity integer value for each vector element.

Syntax

Fortran:

```
call vsfloor( n, a, y )
```

```
call vdfloor( n, a, y )
```

C:

```
vsFloor( n, a, y );
```

```
vdFloor( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vsfloor DOUBLE PRECISION for vdfloor Fortran 90: REAL, INTENT (IN) for vsfloor DOUBLE PRECISION, INTENT (IN) for vdfloor C: const float* for vsFloor const double* for vdFloor	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vsfloor DOUBLE PRECISION for vdfloor Fortran 90: REAL, INTENT (OUT) for vsfloor DOUBLE PRECISION, INTENT (OUT) for vdfloor C: float* for vsFloor double* for vdFloor	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Ceil

Computes a rounded towards plus infinity integer value for each vector element.

Syntax

Fortran:

```
call vsceil( n, a, y )
call vdceil( n, a, y )
```

C:

```
vsCeil( n, a, y );
vdCeil( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsceil DOUBLE PRECISION for vdceil Fortran 90: REAL, INTENT (IN) for vsceil DOUBLE PRECISION, INTENT (IN) for vdceil C: const float* for vsCeil const double* for vdCeil	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsceil DOUBLE PRECISION for vdceil Fortran 90: REAL, INTENT (OUT) for vsceil DOUBLE PRECISION, INTENT (OUT) for vdceil C: float* for vsCeil double* for vdCeil	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Trunc

Computes a rounded towards zero integer value for each vector element.

Syntax

Fortran:

```
call vstrunc( n, a, y )
call vdtrunc( n, a, y )
```

C:

```
vsTrunc( n, a, y );
vdTrunc( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the number of elements to be calculated.

Name	Type	Description
	C: const int	
<i>a</i>	FORTRAN 77: REAL for vstrunc DOUBLE PRECISION for vdtrunc Fortran 90: REAL, INTENT (IN) for vstrunc DOUBLE PRECISION, INTENT (IN) for vdtrunc C: const float* for vsTrunc const double* for vdTrunc	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vstrunc DOUBLE PRECISION for vdtrunc Fortran 90: REAL, INTENT (OUT) for vstrunc DOUBLE PRECISION, INTENT (OUT) for vdtrunc C: float* for vsTrunc double* for vdTrunc	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

v?Round

Computes a rounded to nearest integer value for each vector element.

Syntax

Fortran:

```
call vsround( n, a, y )
call vdround( n, a, y )
```

C:

```
vsRound( n, a, y );
vdRound( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsround DOUBLE PRECISION for vdround Fortran 90: REAL, INTENT (IN) for vsround DOUBLE PRECISION, INTENT (IN) for vdround C: const float* for vsRound const double* for vdRound	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsround DOUBLE PRECISION for vdround Fortran 90: REAL, INTENT (OUT) for vsround DOUBLE PRECISION, INTENT (OUT) for vdround C: float* for vsRound double* for vdRound	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

Halfway values, that is, 0.5, -1.5, and the like, are rounded off away from zero. That is, 0.5 -> 1, -1.5 -> -2, etc.

v?NearbyInt

Computes a rounded integer value in a current rounding mode for each vector element.

Syntax

Fortran:

```
call vsnearbyint( n, a, y )  
call vdnearbyint( n, a, y )
```

C:

```
vsNearbyInt( n, a, y );  
vdNearbyInt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsnear- byint DOUBLE PRECISION for vdnear- byint Fortran 90: REAL, INTENT (IN) for vsnearbyint DOUBLE PRECISION, INTENT (IN) for vdnearbyint C: const float* for vsNear- byInt const double* for vdNearbyInt	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsnear- byint DOUBLE PRECISION for vdnear- byint Fortran 90: REAL, INTENT (OUT) for vsnearbyint DOUBLE PRECISION, INTENT (OUT) for vdnearbyint C: float* for vsNearbyInt	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	double* for vdNearbyInt	

Description

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values.

v?Rint

Computes a rounded integer value in a current rounding mode for each vector element with inexact result exception raised for each changed value.

Syntax

Fortran:

```
call vsrint( n, a, y )
call vdrint( n, a, y )
```

C:

```
vsRint( n, a, y );
vdRint( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsrint DOUBLE PRECISION for vdrint Fortran 90: REAL, INTENT(IN) for vsrint	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdrint	
	C: const float* for vsRint const double* for vdRint	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsrint DOUBLE PRECISION for vdrint Fortran 90: REAL, INTENT(OUT) for vsrint DOUBLE PRECISION, INTENT(OUT) for vdrint C: float* for vsRint double* for vdRint	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values. For each changed value, inexact result exception is raised.

v?Modf

Computes a truncated integer value and remaining fraction part for each vector element.

Syntax

Fortran:

```
call vsmodf( n, a, y, z )
call vdmodf( n, a, y, z )
```

C:

```
vsModf( n, a, y, z );  
vdModf( n, a, y, z );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsmodf DOUBLE PRECISION for vdmodf Fortran 90: REAL, INTENT (IN) for vsmodf DOUBLE PRECISION, INTENT (IN) for vdmodf C: const float* for vsModf const double* for vdModf	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y, z</i>	FORTRAN 77: REAL for vsmodf DOUBLE PRECISION for vdmodf Fortran 90: REAL, INTENT (OUT) for vsmodf DOUBLE PRECISION, INTENT (OUT) for vdmodf C: float* for vsModf	FORTRAN: Array, specifies the output vector <i>y</i> and <i>z</i> . C: Pointer to an array that contains the output vector <i>y</i> and <i>z</i> .

Name	Type	Description
	double* for vdModf	

VML Pack/Unpack Functions

This section describes VML functions which convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing and mask indexing (see [Appendix B](#) for details on vector indexing methods).

[Table 9-12](#) lists available VML Pack/Unpack functions, together with data types and indexing methods associated with them.

Table 9-12 VML Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
v?Pack	s, d	I, V, M	Gathers elements of arrays, indexed by different methods.
v?Unpack	s, d	I, V, M	Scatters vector elements to arrays with different indexing.

v?Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax

Fortran:

```
call vspacki( n, a, inca, y )
call vspackv( n, a, ia, y )
call vspackm( n, a, ma, y )
call vdpacki( n, a, inca, y )
call vdpackv( n, a, ia, y )
call vdpackm( n, a, ma, y )
```

C:

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vspacki, vspackv, vspackm DOUBLE PRECISION for vdpacki, vdpackv, vdpackm Fortran 90: REAL, INTENT (IN) for vspacki, vspackv, vspackm DOUBLE PRECISION, INTENT (IN) for vdpacki, vdpackv, vdpackm C: const float* for vsPackI, vsPackV, vsPackM const double* for vdPackI, vdPackV, vdPackM	FORTRAN: Array, DIMENSION at least (1 + (n-1)*inca) for vspacki/vdpacki, Array, DIMENSION at least max(n, max(ia[j])), j=0, ..., n-1 for vspackv/vdpackv, Array, DIMENSION at least n for vspackm/vdpackm. Specifies the input vector <i>a</i> . C: Specifies pointer to an array that contains the input vector <i>a</i> . Size of the array must be: at least (1 + (n-1)*inca) for vsPackI/vdPackI, at least max(n, max(ia[j])), j=0, ..., n-1 for vsPackV/vdPackV, at least n for vsPackM/vdPackM.

Name	Type	Description
<i>inca</i>	FORTRAN 77: INTEGER for vspacki, vdpacki Fortran 90: INTEGER, INTENT (IN) for vspacki, vdpacki C: const int for vsPackI, vdPackI	Specifies the increment for the elements of <i>a</i> .
<i>ia</i>	FORTRAN 77: INTEGER for vspackv, vdpackv Fortran 90: INTEGER, INTENT (IN) for vspackv, vdpackv C: const int* for vsPackV, vdPackV	FORTRAN: Array, DIMENSION at least <i>n</i> . Specifies the index vector for the elements of <i>a</i> . C: Specifies the pointer to an array of size at least <i>n</i> that contains the index vector for the elements of <i>a</i> .
<i>ma</i>	FORTRAN 77: INTEGER for vspackm, vdpackm Fortran 90: INTEGER, INTENT (IN) for vspackm, vdpackm C: const int* for vsPackM, vdPackM	FORTRAN: Array, DIMENSION at least <i>n</i> , Specifies the mask vector for the elements of <i>a</i> . C: Specifies the pointer to an array of size at least <i>n</i> that contains the mask vector for the elements of <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vspacki, vspackv, vspackm DOUBLE PRECISION for vdpacki, vdpackv, vdpackm	FORTRAN: Array, DIMENSION at least <i>n</i> . Specifies the output vector <i>y</i> . C: Pointer to an array of size at least <i>n</i> that contains the output vector <i>y</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (OUT) for vspacki, vspackv, vspackm	
	DOUBLE PRECISION, INTENT (OUT) for vdpacki, vd- packv, vdpackm	
	C: float* for vsPackI, vsPackV, vsPackM	
	double* for vdPackI, vdPackV, vdPackM	

v?Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

Fortran:

```
call vsunpacki( n, a, y, incy )
call vsunpackv( n, a, y, iy )
call vsunpackm( n, a, y, my )
call vdunpacki( n, a, y, incy )
call vdunpackv( n, a, y, iy )
call vdunpackm( n, a, y, my )
```

C:

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
```

Input Parameters

Name	Type	Description
<i>n</i>	<p>FORTRAN 77: INTEGER</p> <p>Fortran 90: INTEGER, INTENT (IN)</p> <p>C: const int</p>	Specifies the number of elements to be calculated.
<i>a</i>	<p>FORTRAN 77: REAL for vsunpacki, vsunpackv, vsunpackm</p> <p>DOUBLE PRECISION for vdunpacki, vdunpackv, vdunpackm.</p> <p>Fortran 90: REAL, INTENT (IN) for vsunpacki, vsunpackv, vsunpackm</p> <p>DOUBLE PRECISION, INTENT (IN) for vdunpacki, vdunpackv, vdunpackm.</p> <p>C: const float* for vsUnpackI, vsUnpackV, vsUnpackM</p> <p>const double* for vdUnpackI, vdUnpackV, vdUnpackM</p>	<p>FORTRAN: Array, DIMENSION at least <i>n</i>. Specifies the input vector <i>a</i>.</p> <p>C: Specifies the pointer to an array of size at least <i>n</i> that contains the input vector <i>a</i>.</p>

Name	Type	Description
<i>incy</i>	<p>FORTRAN 77: INTEGER for vsunpacki, vdunpacki.</p> <p>Fortran 90: INTEGER, INTENT (IN) for vsunpacki, vdunpacki.</p> <p>C: const int for vsUnpackI, vdUnpackI.</p>	Specifies the increment for the elements of <i>y</i> .
<i>iy</i>	<p>FORTRAN 77: INTEGER for vsunpackv, vdunpackv</p> <p>Fortran 90: INTEGER, INTENT (IN) for vsunpackv, vdunpackv</p> <p>C: const int* for vsUnpackV, vdUnpackV</p>	<p>FORTRAN: Array, DIMENSION at least <i>n</i>. Specifies the index vector for the elements of <i>y</i>.</p> <p>C: Specifies the pointer to an array of size at least <i>n</i> that contains the index vector for the elements of <i>a</i>.</p>
<i>my</i>	<p>FORTRAN 77: INTEGER for vsunpackm, vdunpackm</p> <p>Fortran 90: INTEGER, INTENT (IN) for vsunpackm, vdunpackm</p> <p>C: const int* for vsUnpackM, vdUnpackM</p>	<p>FORTRAN: Array, DIMENSION at least <i>n</i>, Specifies the mask vector for the elements of <i>y</i>.</p> <p>C: Specifies the pointer to an array of size at least <i>n</i> that contains the mask vector for the elements of <i>a</i>.</p>

Output Parameters

Name	Type	Description
<i>y</i>	<p>FORTRAN 77: REAL for vsunpacki, vsunpackv, vsunpackm</p> <p>DOUBLE PRECISION for vdunpacki, vdunpackv, vdunpackm</p>	<p>FORTRAN: Array, DIMENSION at least $(1 + (n-1) * incy)$ for vsunpacki,</p> <p>at least $\max(n, \max(iy[j]))$, $j=0, \dots, n-1$, for vsunpackv,</p>

Name	Type	Description
	Fortran 90: REAL, INTENT (OUT) for vsunpacki, vsunpackv, vsunpackm DOUBLE PRECISION, INTENT (OUT) for vdunpacki, vdunpackv, vdunpackm C: float* for vsUnpackI, vsUnpackV, vsUnpackM double* for vdUnpackI, vdUnpackV, vdUnpackM	at least n for vsunpackm/vdunpackm C: Specifies the pointer to an array that contains the output vector y . Size of the array must be: at least $(1 + (n-1) * incy)$ for vsUnPackI, at least $\max(n, \max(ia[j]), j=0, \dots, n-1)$ for vsUnPackV, at least n for vsUnPackM.

VML Service Functions

VML Service functions allow the user to set /get the accuracy mode, and set/get the error code. All these functions are available both in Fortran- and C- interfaces. [Table 9-13](#) lists available VML Service functions and their short description.

Table 9-13 VML Service Functions

Function Short Name	Description
SetMode	Sets the VML mode
GetMode	Gets the VML mode
SetErrStatus	Sets the VML error status
GetErrStatus	Gets the VML error status
ClearErrStatus	Clears the VML error status
SetErrorCallBack	Sets the additional error handler callback function
GetErrorCallBack	Gets the additional error handler callback function
ClearErrorCallBack	Deletes the additional error handler callback function

SetMode

Sets a new mode for VML functions according to *mode* parameter and stores the previous VML mode to *oldmode*.

Syntax

Fortran:

```
oldmode = vmlsetmode( mode )
```

C:

```
oldmode = vmlSetMode( mode );
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const unsigned int	Specifies the VML mode to be set.

Output Parameters

Name	Type	Description
<i>oldmode</i>	FORTRAN: INTEGER C: int	Specifies the former VML mode.

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The *mode* parameter is designed to control accuracy, FPU, error handling and threading options. [Table 9-14](#) lists values of the *mode* parameter. All other possible values of the *mode* parameter may be obtained from these values by using bitwise OR (|) operation to combine one value

for accuracy, one for FPU, and one for error control options. The default value of the *mode* parameter is `VML_HA | VML_ERRMODE_DEFAULT | VML_NUM_THREADES_OMP_AUTO`. Thus, the current FPU control word (FPU precision and the rounding method) is used by default.

If any VML mathematical function requires different FPU precision, or rounding method, it changes these options automatically and then restores the former values. The *mode* parameter enables you to minimize switching the internal FPU mode inside each VML mathematical function that works with similar precision and accuracy settings. To accomplish this, set the *mode* parameter to `VML_FLOAT_CONSISTENT` for single precision real and complex functions, or to `VML_DOUBLE_CONSISTENT` for double precision real and complex functions. These values of the *mode* parameter are the optimal choice for the respective function groups, as they are required for most of the VML mathematical functions. After the execution is over, set the *mode* to `VML_RESTORE` if you need to restore the previous FPU mode.

Table 9-14 Values of the *mode* Parameter

Value of <i>mode</i>	Description
Accuracy Control	
<code>VML_HA</code>	High accuracy versions of VML functions will be used.
<code>VML_LA</code>	Low accuracy versions of VML functions will be used.
<code>VML_EP</code>	Enhanced Performance accuracy versions of VML functions will be used.
Additional FPU Mode Control	
<code>VML_FLOAT_CONSISTENT</code>	The optimal FPU mode (control word) for single precision functions is set, and the previous FPU mode is saved.
<code>VML_DOUBLE_CONSISTENT</code>	The optimal FPU mode (control word) for double precision functions is set, and the previous FPU mode is saved.
<code>VML_RESTORE</code>	The previously saved FPU mode is restored.
Error Mode Control	
<code>VML_ERRMODE_IGNORE</code>	No action is set for computation errors.
<code>VML_ERRMODE_ERRNO</code>	On error, the <i>errno</i> variable is set.
<code>VML_ERRMODE_STDERR</code>	On error, the error text information is written to <i>stderr</i> .
<code>VML_ERRMODE_EXCEPT</code>	On error, an exception is raised.
<code>VML_ERRMODE_CALLBACK</code>	On error, an additional error handler function is called.
<code>VML_ERRMODE_DEFAULT</code>	On error, the <i>errno</i> variable is set, an exception is raised, and an additional error handler function is called.
Treading Mode Control	

Value of <i>mode</i>	Description
VML_NUM_THREADS_OMP_AUTO	This is default behavior. Maximum number of threads is determined by environmental variable OMP_NUM_THREADS and can be overridden by OpenMP* function <code>omp_set_num_threads()</code> . For performance reasons VML threading logic can use fewer number of threads.
VML_NUM_THREADS_OMP_FIXED	Number of threads is determined by environmental variable OMP_NUM_THREADS and can be overridden by OpenMP* function <code>omp_set_num_threads()</code> . Use this mode to disable VML threading logic.

Examples

Several examples of calling the function `vmlSetMode()` with different values of the *mode* parameter are given below:

Fortran:

```
oldmode = vmlsetmode( VML_LA )
call vmlsetmode( IOR(VML_LA, IOR(VML_FLOAT_CONSISTENT,
VML_ERRMODE_IGNORE )))
call vmlsetmode( VML_RESTORE)
call vmlsetmode( VML_NUM_THREADS_OMP_FIXED)
```

C:

```
vmlSetMode( VML_LA );
vmlSetMode( VML_LA | VML_FLOAT_CONSISTENT | VML_ERRMODE_IGNORE
);
vmlSetMode( VML_RESTORE);
vmlSetMode( VML_NUM_THREADS_OMP_FIXED);
```

GetMode

Gets the VML mode.

Syntax

Fortran:

```
mod = vmlgetmode()
```

C:

```
mod = vmlGetMode( void );
```

Output Parameters

Name	Type	Description
<i>mod</i>	FORTTRAN: INTEGER C: int	Specifies the packed <i>mode</i> parameter.

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `vmlGetMode()` returns the VML *mode* parameter that controls accuracy, FPU, and error handling options. The *mod* variable value is some combination of the values listed in the [Table 9-14](#). You can obtain some of these values using the respective mask from the [Table 9-15](#).

Table 9-15 Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy <i>mode</i> selection.
VML_FPUMODE_MASK	Specifies mask for FPU <i>mode</i> selection.
VML_ERRMODE_MASK	Specifies mask for error <i>mode</i> selection.

See example below:

Examples

Fortran:

```

mod = vmlgetmode()
accm = IAND(mod, VML_ACCURACY_MASK)
fpum = IAND(mod, VML_FPUMODE_MASK)
errm = IAND(mod, VML_ERRMODE_MASK)

```

C:

```

accm = vmlGetMode(void ) & VML_ACCURACY_MASK;
fpum = vmlGetMode(void ) & VML_FPUMODE_MASK;
errm = vmlGetMode(void ) & VML_ERRMODE_MASK;

```

SetErrStatus

Sets the new VML error status according to `err` and stores the previous VML error status to `olderr`.

Syntax

Fortran:

```
olderr = vmlseterrstatus( err )
```

C:

```
olderr = vmlSetErrStatus( err );
```

Input Parameters

Name	Type	Description
<code>err</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the VML error status to be set.

Output Parameters

Name	Type	Description
<i>olderr</i>	FORTRAN: INTEGER C: int	Specifies the former VML error status.

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

Table 9-16 lists possible values of the *err* parameter.

Table 9-16 Values of the VML Error Status

Error Status	Description
VML_STATUS_OK	The execution was completed successfully.
VML_STATUS_BADSIZE	The array dimension is not positive.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of array values caused a singularity.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
vmlSetErrStatus( VML_STATUS_OK );
vmlSetErrStatus( VML_STATUS_ERRDOM );
vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

GetErrStatus

Gets the VML error status.

Syntax

Fortran:

```
err = vmlgeterrstatus( )
```

C:

```
err = vmlGetErrStatus( void );
```

Output Parameters

Name	Type	Description
<i>err</i>	FORTTRAN: INTEGER C: int	Specifies the VML error status.

ClearErrStatus

Sets the VML error status to VML_STATUS_OK and stores the previous VML error status to olderr.

Syntax

Fortran:

```
olderr = vmlclearerrstatus( )
```

C:

```
olderr = vmlClearErrStatus( void );
```

Output Parameters

Name	Type	Description
<i>olderr</i>	FORTTRAN: INTEGER C: int	Specifies the former VML error status.

SetErrorCallBack

Sets the additional error handler callback function and gets the old callback function.

Syntax

Fortran:

```
oldcallback = vmlseterrorcallback( callback )
```

C:

```
oldcallback = vmlSetErrorCallBack( callback );
```

Input Parameters

Name	Description
FORTTRAN: Address of the callback function. <i>callback</i>	<p>The callback function has the following format:</p> <pre> INTEGER FUNCTION ERRFUNC(par) TYPE (ERROR_STRUCTURE) par ! ... ! user error processing ! ... ERRFUNC = 0 ! if ERRFUNC= 0 - standard VML error handler ! is called after the callback ! if ERRFUNC != 0 - standard VML error handler ! is not called END </pre>

Name	Description
	<p>The passed error structure is defined as follows:</p> <pre>TYPE ERROR_STRUCTURE SEQUENCE INTEGER*4 ICODE INTEGER*4 IINDEX REAL*8 DBA1 REAL*8 DBA2 REAL*8 DBR1 REAL*8 DBR2 CHARACTER(64) CFUNCNAME INTEGER*4 IFUNCNAMELEN END TYPE ERROR_STRUCTURE</pre>
C: <i>callback</i>	<p>Pointer to the callback function. The callback function has the following format:</p> <pre>static int __stdcall MyHandler(DefVmlErrorContext* pContext) { /* Handler body */ };</pre>

Name	Description
	<p>The passed error structure is defined as follows:</p> <pre>typedef struct _DefVmlErrorContext { int iCode; /* Error status value */ int iIndex; /* Index for bad array element, or bad array dimension, or bad array pointer */ double dbA1; /* Error argument 1 */ double dbA2; /* Error argument 2 */ double dbR1; /* Error result 1 */ double dbR2; /* Error result 2 */ char cFuncName[64]; /* Function name */ int iFuncNameLen; /* Length of functionname*/ } DefVmlErrorContext;</pre>

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER C: int	<p>FORTTRAN: Address of the former callback function.</p> <p>C: Pointer to the former callback function.</p>

NOTE. FORTRAN 77 support is unavailable for this function.

Description

This function is declared in `mk1_vml.fi` for Fortran 90 interface and in `mk1_vml_functions.h` for C interface.

The callback function is called on each VML mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see [Table 9-14](#)).

Use the `vmlSetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns 0.

GetErrorCallBack

Gets the additional error handler callback function.

Syntax

Fortran:

```
callback = vmlgeterrorcallback( )
```

C:

```
callback = vmlGetErrorCallBack( void );
```

Output Parameters

Name	Description
<i>callback</i>	Fortran 90: Address of the callback function C: Pointer to the callback function

NOTE. FORTRAN 77 support is unavailable for this function.

ClearErrorCallback

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

Fortran:

oldcallback = vmlclearerrorcallback()

C:

oldcallback = vmlClearErrorCallBack(void);

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER C: int	FORTTRAN: Address of the former callback function C: Pointer to the former callback function

NOTE. FORTRAN 77 support is unavailable for this function.

Statistical Functions

Statistical functions in Intel® MKL are known as Vector Statistical Library (VSL) that is designed for the purpose of

- generating vectors of pseudorandom and quasi-random numbers
- performing mathematical operations of convolution and correlation.

The corresponding functionality is described in the respective [Random Number Generators](#) and [Convolution and Correlation](#) sections.

Random Number Generators

VSL provides a set of routines implementing commonly used pseudo- or quasi-random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and the library of vector mathematical functions (VML, see [Chapter 9, “Vector Mathematical Functions”](#)).

VSL provides interfaces both for FORTRAN and C languages. For users of the C and C++ languages the `mkl_vsl.h` header file is provided. For users of the Fortran 90 or Fortran 95 language the `mkl_vsl.fi` header file is provided. For users of the FORTRAN 77 language the `mkl_vsl.f77` header file is provided. All header files are found in the following directory:

```
${MKL}/include
```

The `mkl_vsl.fi` header is intended for using via the Fortran `include` clause and is compatible with both standard forms of F90/F95 sources — the free and 72-columns fixed forms. If you need to use the VSL interface with 80- or 132-columns fixed form sources, you may add a new file to your project. That file is formatted as a 72-columns fixed-form source and consists of a single `include` clause as follows:

```
include 'mkl_vsl.fi'
```

This `include` clause causes the compiler to generate the module files `mkl_vsl.mod` and `mkl_vsl_type.mod`, which are used to process the Fortran use clauses referencing to the VSL interface:

```
use mkl_vsl_type
use mkl_vsl
```

Because of this specific feature, you do not need to include the `mkl_vsl.fi` header into each source of your project. You only need to include the header into some of the sources. In any case, make sure that the sources that depend on the VSL interface are compiled after those that include the header so that the module files `mkl_vsl.mod` and `mkl_vsl_type.mod` are generated prior to using them.

The `mkl_vsl.f77` header is intended for using via the Fortran `include` clause as follows:

```
include 'mkl_vsl.f77'
```

NOTE. For Fortran 90 interface, VSL provides both subroutine-style interface and function-style interface. Default interface in this case is a function-style interface. Function-style interface, unlike subroutine-style interface, allows the user to get error status of each routine. Subroutine-style interface is provided for backward compatibility only. To use subroutine-style interface, manually include `mkl_vsl_subroutine.fi` file instead of `mkl_vsl.fi` by changing the line `include 'mkl_vsl.fi'` in `include\mkl.fi` with the line `include 'mkl_vsl_subroutine.fi'`.

For FORTRAN 77 interface, VSL provides only function-style interface.

All VSL routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are either pseudorandom number generators or quasi-random number generators. Detailed description of the generators can be found in [Distribution Generators](#) section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Routines](#) section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Routines](#) section).

The last two categories are referred to as service routines.

Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to 'Random Numbers' section in [VSL Notes](#) document provided with Intel® MKL.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VSL Notes](#) for the description of methods available for each generator.

The *stream descriptor* specifies which BRNG should be used in a given transformation method. See 'Random Streams and RNGs in Parallel Computation' section of [VSL Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \dots\}$.
Z	The set of integers $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$.
R	The set of real numbers.
$\lfloor a \rfloor$	The floor of a (the largest integer less than or equal to a).
\oplus or xor	Bitwise exclusive OR.
C_{α}^{κ} or $\binom{\alpha}{\kappa}$	Binomial coefficient or combination ($\alpha \in R, \alpha \geq 0; \kappa \in N \cup \{0\}$).
	$C_{\alpha}^{\kappa} = 1$
	For $\alpha \geq \kappa$ binomial coefficient is defined as
	$C_{\alpha}^{\kappa} = \frac{\alpha(\alpha - 1) \dots (\alpha - \kappa + 1)}{\kappa!}$
	If $\alpha < \kappa$, then
	$C_{\alpha}^{\kappa} = 0$
$\Phi(x)$	Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

defined over $-\infty < x < +\infty$.

$\Phi(-\infty) = 0$, $\Phi(+\infty) = 1$.

$\Gamma(\alpha)$

The complete gamma function

$$\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1} e^{-t} dt$$

where $\alpha > 0$.

$B(p, q)$

The complete beta function

$$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$$

where $p > 0$ and $q > 0$.

$LCG(a, c, m)$

Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where a is called the *multiplier*, c is called the *increment*, and m is called the *modulus* of the generator.

$MCG(a, m)$

Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment c is taken to be 0.

$GFSR(p, q)$

Generalized Feedback Shift Register Generator

$$x_n = x_{n-p} \oplus x_{n-q}.$$

Naming Conventions

The names of all VSL functions in FORTRAN are lowercase; names in C may contain both lowercase and uppercase letters.

The names of generator routines have the following structure:

`v<type of result>rng<distribution>` for FORTRAN-interface

`v<type of result>Rng<distribution>` for C-interface,

where `v` is the prefix of a VSL vector function, and the field `<type of result>` is either `s`, `d`, or `i` and specifies one of the following types:

<code>s</code>	REAL for FORTRAN-interface float for C-interface
<code>d</code>	DOUBLE PRECISION for FORTRAN-interface double for C-interface
<code>i</code>	INTEGER for FORTRAN-interface int for C-interface

Prefixes `s` and `d` apply to continuous distributions only, prefix `i` applies only to discrete case. The prefix `rng` indicates that the routine is a random generator, and the `<distribution>` field specifies the type of statistical distribution.

Names of service routines follow the template below:

`vsl<name>`,

where `vsl` is the prefix of a VSL service function. The field `<name>` contains a short function name. For a more detailed description of service routines refer to [Service Routines](#) and [Advanced Service Routines](#) sections.

Prototype of each generator routine corresponding to a given probability distribution fits the following structure:

`status = <function name>(method, stream, n, r, [<distribution parameters>]),`

where

- `method` defines the method of generation. A detailed description of this parameter can be found in [Table 10-1](#). See the next page, where the structure of the `method` parameter name is explained.
- `stream` defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- `n` defines the number of random values to be generated. If `n` is less than or equal to zero, no values are generated. Furthermore, if `n` is negative, an error condition is set.
- `r` defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least `n` random numbers.
- `status` defines the error status of a VSL routine. See [Error Reporting](#) section for a detailed description of error status values.

Additional parameters included into `<distribution parameters>` field are individual for each generator routine and are described in detail in [Distribution Generators](#) section.

To invoke a distribution generator, use a call to the respective VSL routine. For example, to obtain a vector r , composed of n independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value a and standard deviation σ , write the following:

for FORTRAN-interface

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

for C-interface

```
status = vsRngGaussian( method,
stream, n, r, a, sigma )
```

The name of a `method` parameter has the following structure:

```
VSL_METHOD_<precision><distribution>_<method>,
```

```
VSL_METHOD_<precision><distribution>_<method>_ACCURATE,
```

where

<code><precision></code>	s	for single precision continuous distribution
	D	for double precision continuous distribution
	I	for discrete distribution
<code><distribution></code>	probability distribution	
<code><method></code>	method name.	

Type of name structure for `method` parameter corresponds to fast and accurate modes of random number generation (see ["Distribution Generators"](#) section and [VSL Notes](#) for details).

Method names `VSL_METHOD_<precision><distribution>_<method>` and `VSL_METHOD_<precision><distribution>_<method>_ACCURATE` should be used with `vsl<precision>Rng<distribution>` function only, where

<code><precision></code>	s	for single precision continuous distribution
	d	for double precision continuous distribution
	i	for discrete distribution
<code><distribution></code>	probability distribution.	

[Table 10-1](#) provides specific predefined values of the `method` name. The third column contains names of the functions that use the given method.

Table 10-1 Values of <method> in method parameter

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous), Uni- form (discrete), Uni- formBits
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula: $x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian , GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas: $x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	Gaussian , GaussianMV , Lognormal
ICDF	Inverse cumulative distribution function method.	Exponential , Laplace , Weibull , Cauchy , Rayleigh , Gumbel , Bernoulli , Geometric , Gaussian , GaussianMV

Method	Short Description	Functions
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	Gamma
CJA	For $\min(p, q) > 1$, Cheng method is used; for $\min(p, q) < 1$, Jöhnk method is used, if $q + K \cdot p^2 + C \leq 0$ ($K = 0.852...$, $C = -0.956...$) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$, method of Jöhnk is used; for $\min(p, q) < 1$, $\max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Jöhnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $n_{trial} \cdot \min(p, 1 - p) \geq 30$ with decomposition into 4 regions: <ul style="list-style-type: none"> – 2 parallelograms – triangle – left exponential tail – right exponential tail 	Binomial
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: <ul style="list-style-type: none"> – rectangular – left exponential tail – right exponential tail 	Hypergeometric

Method	Short Description	Functions
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: <ul style="list-style-type: none">– 2 parallelograms– triangle– left exponential tail– right exponential tail; otherwise, table lookup method is used.	<a>Poisson
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	<a>Poisson , <a>PoissonV
NBAR	Acceptance/rejection method for , <div>$\frac{(a - 1) \cdot (1 - p)}{p} \geq 100$</div> with decomposition into 5 regions: <ul style="list-style-type: none">– rectangular– 2 trapezoid– left exponential tail– right exponential tail	<a>NegBinomial

Basic Generators

- VSL provides the following BRNGs, which differ in speed and other properties:
- the 32-bit multiplicative congruential pseudorandom number generator *MCG* (1132489760, $2^{31} - 1$) [L'Ecuyer99]
 - the 32-bit generalized feedback shift register pseudorandom number generator *GFSR* (250, 103) [Kirkpatrick81]

- the combined multiple recursive pseudorandom number generator *MRG-32k3a* [[L'Ecuyer99a](#)]
- the 59-bit multiplicative congruential pseudorandom number generator *MCG(13¹³, 2⁵⁹)* from NAG Numerical Libraries [[NAG](#)]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [[NAG](#)]
- Mersenne Twister pseudorandom number generator *MT19937* [[Matsumoto98](#)] with period length $2^{19937}-1$ of the produced sequence
- Set of 1024 Mersenne Twister pseudorandom number generators *MT2203* [[Matsumoto98](#)], [[Matsumoto00](#)]. Each of them generates a sequence of period length equal to $2^{2203}-1$. Parameters of the generators provide mutual independence of the corresponding sequences.

Besides these pseudorandom number generators, VSL provides two basic quasi-random number generators:

- Sobol quasi-random number generator [[Sobol76](#)], [[Bratley88](#)], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).
- Niederreiter quasi-random number generator [[Bratley92](#)], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).

See some testing results for the generators in [VSL Notes](#) and comparative performance data at http://www.intel.com/software/products/mkl/data/vsl/vsl_performance_data.htm.

VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

For some basic generators, VSL provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 1024 generators designed to create up to 1024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [[Coddington94](#)].

You may want to design and use your own basic generators. VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

There is also an option to utilize externally generated random numbers in VSL distribution generator routines. For this purpose VSL provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval.

Such basic generators are called the abstract basic random number generators.
See [VSL Notes](#) for a more detailed description of the generator properties.

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Table 10-2 Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MRG32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 1024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$; user-defined dimensions are also available.

Value	Short Description
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.

See [VSL Notes](#) for detailed description.

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. Users have no direct access to these sequences and operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VSL Notes](#) for details.

NOTE. Random streams associated with abstract basic random number generator are called the abstract random streams. See [VSL Notes](#) for detailed description of abstract streams and their use.

User can create unlimited number of random streams by VSL [Service Routines](#) like [NewStream](#) and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine [DeleteStream](#).

VSL provides service functions [SaveStreamF](#) and [LoadStreamF](#) to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VSL Notes](#) for detailed description.

Data Types

FORTRAN 77:

```
INTEGER*4 vslstreamstate(2)
```

Fortran 90:

```
TYPE
  VSL_STREAM_STATE
INTEGER*4 descriptor1
INTEGER*4 descriptor2
END
  TYPE VSL_STREAM_STATE
```

C:

```
typedef (void*) VSLStreamStatePtr;
```

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

Error Reporting

VSL routines return status codes of the performed operation to report errors and warnings to the calling program. Thus, it is up to the application to perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

VSL_ERROR_<ERROR_NAME> - indicates VSL errors
VSL_WARNING_<WARNING_NAME> - indicates VSL warnings.

VSL errors are of negative values while warnings are of positive values. The status code of zero value indicates that the operation is completed successfully: VSL_ERROR_OK (or synonymic VSL_STATUS_OK).

Table 10-3 Status Codes and Messages

Status Code	Message
VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Input argument value is not valid.
VSL_ERROR_NULL_PTR	Input pointer argument is NULL.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory.

Status Code	Message
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_ERROR_BAD_STREAM	The random stream is invalid.
VSL_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_ERROR_FILE_READ	Indicates an error in reading the file.
VSL_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_BAD_FILE_FORMAT	File format is unknown.
VSL_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_ERROR_BAD_STREAM_STATE_SIZE	The value in <code>StreamStateSize</code> field is bad.
VSL_ERROR_BAD_WORD_SIZE	The value in <code>WordSize</code> field is bad.
VSL_ERROR_BAD_NSEEDS	The value in <code>NSeeds</code> field is bad.
VSL_ERROR_BAD_NBITS	The value in <code>NBits</code> field is bad.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.

VSL Usage Model

A typical algorithm for VSL random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream/streams. Function `vslDeleteStream`.

NOTE. You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following C example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters $\mu = 5$ and $\sigma = 2$. Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

C Example of VSL Usage

```
#include <stdio.h>
#include "mkl_vsl.h"

int main();
{
    double r[1000]; /* buffer for random numbers */
    double s; /* average */
    VSLStreamStatePtr stream;
    int i, j;

    /* Initializing */
    s = 0.0;
    vslNewStream( &stream, VSL_BRNG_MT19937, 777 );

    /* Generating */
    for ( i=0; i<10; i++ );
    {
        vdRngGaussian( VSL_METHOD_DGAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0 );
        for ( j=0; j<1000; j++ );
        {
            s += r[j];
        }
    }
}
```

```

}
s /= 10000.0;

/* Deleting the stream */
vslDeleteStream( &stream );

/* Printing results */
printf( "Sample mean of normal distribution = %f\n", s );

return 0;
}

```

The Fortran version of the same example is below:

Fortran Example of VSL Usage

```

include 'mkl_vsl.fi'

program MKL_VSL_GAUSSIAN

USE MKL_VSL_TYPE
USE MKL_VSL

real(kind=8) r(1000) ! buffer for random numbers
real(kind=8) s      ! average
real(kind=8) a, sigma ! parameters of normal distribution

TYPE (VSL_STREAM_STATE) :: stream

integer(kind=4) errcode
integer(kind=4) i,j
integer brng,method,seed,n

n = 1000
s = 0.0
a = 5.0
sigma = 2.0
brng=VSL_BRNG_MT19937
method=VSL_METHOD_DGAUSSIAN_ICDF
seed=777

! ***** Initializing *****
errcode=vslnewstream( stream, brng, seed )

! ***** Generating *****
do i = 1,10
  errcode=vdrnggaussian( method, stream, n, r, a, sigma )
  do j = 1, 1000
    s = s + r(j)
  end do
end do

```

```
end do

s = s / 10000.0

! ***** Deinitialize *****
errcode=vsldeltestream( stream )

! ***** Printing results *****
print *, "Sample mean of normal distribution = ", s

end
```

Additionally, examples that demonstrate usage of VSL random number generators are available in the following directories:

```
${MKL}/examples/vslc/source
${MKL}/examples/vslf/source.
```

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. Table 10-4 lists all available service routines

Table 10-4 Service Routines

Routine	Short Description
NewStream	Creates and initializes a random stream.
NewStreamEx	Creates and initializes a random stream for the generators with multiple initial conditions.
iNewAbstractStream	Creates and initializes an abstract random stream for integer arrays.
dNewAbstractStream	Creates and initializes an abstract random stream for double precision floating-point arrays.
sNewAbstractStream	Creates and initializes an abstract random stream for single precision floating-point arrays.
DeleteStream	Deletes previously created stream.
CopyStream	Copies a stream to another stream.

Routine	Short Description
CopyStreamState	Creates a copy of a random stream state.
SaveStreamF	Writes a stream to a binary file.
LoadStreamF	Reads a stream from a binary file.
LeapfrogStream	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
SkipAheadStream	Initializes the stream by the skip-ahead method.
GetStreamStateBrng	Obtains the index of the basic generator responsible for the generation of a given random stream.
GetNumRegBrngs	Obtains the number of currently registered basic generators.

NOTE. In the above table, the `vs1` prefix in the function names is omitted. In the function reference this prefix is always used in function prototypes and code examples.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream ([NewStream](#), [NewStreamEx](#), [CopyStream](#), [CopyStreamState](#), [LeapfrogStream](#), [SkipAheadStream](#)).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream ([DeleteStream](#)).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the [DeleteStream](#) function to delete all the streams afterwards.

NewStream

Creates and initializes a random stream.

Syntax

Fortran:

```
status = vslnewstream( stream, brng, seed )
```

C:

```
status = vslNewStream( &stream, brng, seed );
```

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN 77: INTEGER	Index of the basic generator to initialize the stream. See Table 10-2 for specific value.
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>seed</i>	FORTRAN 77: INTEGER	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that brng can support or is less than 1, then the dimension is assumed to be equal to 1.
	Fortran 90: INTEGER, INTENT (IN)	
	C: const unsigned int	

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4	Stream state descriptor
	stream(2)	
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT)	
	C: VSLStreamStatePtr*	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. See [VSL Notes](#) for a more detailed description of stream initialization for different basic generators.

NOTE. This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vsldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .

NewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

Fortran:

```
status = vslnewstreamex( stream, brng, n, params )
```

C:

```
status = vslNewStreamEx( &stream, brng, n, params );
```

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Index of the basic generator to initialize the stream. See Table 10-2 for specific value.
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of initial conditions contained in <i>params</i>
<i>params</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const unsigned int	Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Stream state descriptor

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use [NewStream](#), which is analogous to [vslNewStreamEx](#) except that it takes only one 32-bit initial condition. In particular, [vslNewStreamEx](#) may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VSL Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VSL Notes](#) for the format for their passing and registration in VSL.

NOTE. This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vslldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .

iNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

Syntax

Fortran:

```
status = vslnewabstractstream( stream, n, ibuf, icallback )
```

C:

```
status = vslNewAbstractStream( &stream, n, ibuf, icallback );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of the array <i>ibuf</i>
<i>ibuf</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const unsigned int	Array of <i>n</i> 32-bit integers
<i>icallback</i>	See <i>Note</i> below	FORTRAN: Address of the callback function used for <i>ibuf</i> update C: Pointer to the callback function used for <i>ibuf</i> update

NOTE. Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION IUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )  
  
INTEGER*4 stream(2)  
  
INTEGER n  
  
INTEGER*4 ibuf(n)  
  
INTEGER nmin  
  
INTEGER nmax  
  
INTEGER idx
```

Format of the callback function in Fortran 90:

```

INTEGER FUNCTION IUPDATEFUNC(C)( stream, n, ibuf, nmin, nmax, idx )

TYPE(VSL_STREAM_STATE), POINTER :: stream[reference]

INTEGER(KIND=4), INTENT(IN)      :: n[reference]

INTEGER(KIND=4), INTENT(OUT)     :: ibuf[reference](0:n-1)

INTEGER(KIND=4), INTENT(IN)      :: nmin[reference]

INTEGER(KIND=4), INTENT(IN)      :: nmax[reference]

INTEGER(KIND=4), INTENT(IN)      :: idx[reference]

```

Format of the callback function in C:

```

int iUpdateFunc( VSLStreamStatePtr stream, int* n, unsigned int ibuf[], int* nmin,
int* nmax, int* idx );

```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-5](#) gives the description of the callback function parameters.

Table 10-5 icallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>ibuf</i>
<i>ibuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 <code>stream(2)</code> Fortran 90: <code>TYPE (VSL_STREAM_STATE),</code> <code>TINTENT (OUT)</code> C: <code>VSLStreamStatePtr*</code>	Descriptor of the stream state structure

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates a new abstract stream and associates it with an integer array *ibuf* and user's callback function *icallback* that is intended for updating of *ibuf* content.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BAD_ARG</code>	Parameter <i>n</i> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <i>stream</i> .
<code>VSL_ERROR_NULL_PTR</code>	Either buffer or callback function parameter is a NULL pointer.

dNewAbstractStream

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

Fortran:

```
status = vsldnewabstractstream( stream, n, dbuf, a, b, dcallback )
```

C:

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of the array <i>dbuf</i>
<i>dbuf</i>	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Array of <i>n</i> double precision floating-point random numbers with uniform distribution over interval (a,b)
<i>a</i>	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Left boundary a
<i>b</i>	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Right boundary b
<i>dcallback</i>	See <i>Note</i> below	FORTTRAN: Address of the callback function used for update of the array <i>dbuf</i> C: Pointer to the callback function used for update of the array <i>dbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE. Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION DUPDATEFUNC( stream, n, dbuf, nmin, nmax, idx )  
  
INTEGER*4 stream(2)  
  
INTEGER n  
  
DOUBLE PRECISION dbuf(n)  
  
INTEGER nmin  
  
INTEGER nmax  
  
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION DUPDATEFUNC[C]( stream, n, dbuf, nmin, nmax, idx )  
  
TYPE (VSL_STREAM_STATE), POINTER :: stream[reference]  
INTEGER (KIND=4), INTENT (IN) :: n[reference]  
REAL (KIND=8), INTENT (OUT) :: dbuf[reference] (0:n-1)  
INTEGER (KIND=4), INTENT (IN) :: nmin[reference]  
INTEGER (KIND=4), INTENT (IN) :: nmax[reference]  
INTEGER (KIND=4), INTENT (IN) :: idx[reference]
```

Format of the callback function in C:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int*  
nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-6](#) gives the description of the callback function parameters.

dcallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>dbuf</i>
<i>dbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a double precision array *dbuf* and user's callback function *dcallback* that is intended for updating of *dbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

sNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

Fortran:

```
status = vslsnewabstractstream( stream, n, sbuf, a, b, scallback )
```

C:

```
status = vslsNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of the array <i>sbuf</i>
<i>sbuf</i>	FORTTRAN 77: REAL Fortran 90: REAL, INTENT (IN) C: const float	Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (<i>a</i> , <i>b</i>)
<i>a</i>	FORTTRAN 77: REAL Fortran 90: REAL, INTENT (IN) C: const float	Left boundary <i>a</i>
<i>b</i>	FORTTRAN 77: REAL Fortran 90: REAL, INTENT (IN) C: const float	Right boundary <i>b</i>

Name	Type	Description
<i>scallback</i>	See Note below	<p>FORTRAN: Address of the callback function used for update of the array <i>sbuf</i></p> <p>C: Pointer to the callback function used for update of the array <i>sbuf</i></p>

Output Parameters

Name	Type	Description
<i>stream</i>	<p>FORTRAN 77: INTEGER*4 stream(2)</p> <p>Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT)</p> <p>C: VSLStreamStatePtr*</p>	Descriptor of the stream state structure

NOTE. Format of the callback function in FORTRAN 77:

```

INTEGER FUNCTION SUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
REAL sbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx

```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION SUPDATEFUNC(C)( stream, n, sbuf, nmin, nmax, idx )  
  
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]  
  
INTEGER(KIND=4),INTENT(IN)      :: n[reference]  
  
REAL(KIND=4),    INTENT(OUT)    :: sbuf[reference](0:n-1)  
  
INTEGER(KIND=4),INTENT(IN)      :: nmin[reference]  
  
INTEGER(KIND=4),INTENT(IN)      :: nmax[reference]  
  
INTEGER(KIND=4),INTENT(IN)      :: idx[reference]
```

Format of the callback function in C:

```
int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int*  
nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-7](#) gives the description of the callback function parameters.

Table 10-7 **callback** Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>sbuf</i>
<i>sbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$.

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a single precision array *sbuf* and user's callback function *callback* that is intended for updating of *sbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

DeleteStream

Deletes a random stream.

Syntax

Fortran:

```
status = vsldeletestream( stream )
```

C:

```
status = vslDeleteStream( &stream );
```

Input/Output Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	FORTTRAN: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the descriptor becomes invalid. C: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to NULL.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function deletes the random stream created by one of the initialization functions.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>srcstream</code> parameter is a NULL pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<code>srcstream</code> is not a valid random stream.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <code>newstream</code> .

CopyStream

Creates a copy of a random stream.

Syntax

Fortran:

```
status = vslcopystream( newstream, srcstream )
```

C:

```
status = vslCopyStream( &newstream, srcstream );
```

Input Parameters

Name	Type	Description
<code>srcstream</code>	FORTTRAN 77: <code>INTEGER*4</code> <code>srcstream(2)</code> Fortran 90: <code>TYPE(VSL_STREAM_STATE),</code> <code>INTENT(IN)</code> C: <code>const</code> <code>VSLStreamStatePtr</code>	FORTTRAN: Descriptor of the stream to be copied C: Pointer to the stream state structure to be copied

Output Parameters

Name	Type	Description
<i>newstream</i>	FORTRAN 77: INTEGER*4 newstream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Copied stream descriptor

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>newstream</i> .

CopyStreamState

Creates a copy of a random stream state.

Syntax

Fortran:

```
status = vslcopystreamstate( deststream, srcstream )
```

C:

```
status = vslCopyStreamState( deststream, srcstream );
```

Input Parameters

Name	Type	Description
<i>srcstream</i>	FORTTRAN 77: INTEGER*4 srcstream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: const VSLStreamStatePtr	FORTTRAN: Descriptor of the destination stream where the state of <i>srcstream</i> stream is copied C: Pointer to the stream state structure, from which the state structure is copied

Output Parameters

Name	Type	Description
<i>deststream</i>	FORTTRAN 77: INTEGER*4 deststream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream with the state to be copied C: Pointer to the stream state structure where the stream state is copied

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike [CopyStream](#) function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `CopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>srcstream</i> or <i>deststream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.
VSL_ERROR_BRNGS_INCOMPATIBLE	BRNG associated with <i>srcstream</i> is not compatible with BRNG associated with <i>deststream</i> .

SaveStreamF

Writes random stream descriptive data to binary file.

Syntax

Fortran:

```
errstatus = vslsavestreamf( stream, fname )
```

C:

```
errstatus = vslSaveStreamF( stream, fname );
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN) C: const VSLStreamStatePtr	Random stream to be written to the file
<i>fname</i>	FORTRAN 77: CHARACTER(*) Fortran 90: CHARACTER(*), INTENT(IN)	FORTRAN: File name specified as a C-style null-terminated string C: File name specified as a Fortran-style character string

Name	Type	Description
	C: <code>const char*</code>	

Output Parameters

Name	Type	Description
<i>errstatus</i>	FORTRAN: <code>INTEGER</code> C: <code>int</code>	Error status of the operation

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function writes the random stream descriptive data to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. Random stream *stream* must be a valid stream created by [NewStream](#)-like or [CopyStream](#)-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. Random stream can be read from the binary file using [LoadStreamF](#) function.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	Either <i>fname</i> or <i>stream</i> is a NULL pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_ERROR_FILE_OPEN</code>	Indicates an error in opening the file.
<code>VSL_ERROR_FILE_WRITE</code>	Indicates an error in writing the file.
<code>VSL_ERROR_FILE_CLOSE</code>	Indicates an error in closing the file.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for internal needs.

LoadStreamF

Creates new stream and reads stream descriptive data from binary file.

Syntax

Fortran:

```
errstatus = vslloadstreamf( stream, fname )
```

C:

```
errstatus = vslLoadStreamF( &stream, fname );
```

Input Parameters

Name	Type	Description
<i>fname</i>	FORTRAN 77: CHARACTER(*)	FORTRAN: File name specified as a C-style null-terminated string
	Fortran 90: CHARACTER(*), INTENT(IN)	C: File name specified as a Fortran-style character string
	C: const char*	

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	FORTRAN: Descriptor of a new random stream
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT)	C: Pointer to a new random stream
	C: VSLStreamStatePtr*	
<i>errstatus</i>	FORTRAN: INTEGER C: int	Error status of the operation

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates a new stream and reads stream descriptive data from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use [SaveStreamF](#) function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>fname</i> is a NULL pointer.
VSL_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_ERROR_BAD_FILE_FORMAT	Unknown file format.
VSL_ERROR_UNSUPPORTED_FILE_VER	File format version is unsupported.

LeapfrogStream

Initializes a stream using the leapfrog method.

Syntax

Fortran:

```
status = vslleapfrogstream( stream, k, nstreams )
```

C:

```
status = vslLeapfrogStream( stream, k, nstreams );
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream to which leapfrog method is applied C: Pointer to the stream state structure to which leapfrog method is applied
<i>k</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Index of the computational node, or stream number
<i>nstreams</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Largest number of computational nodes, or stride

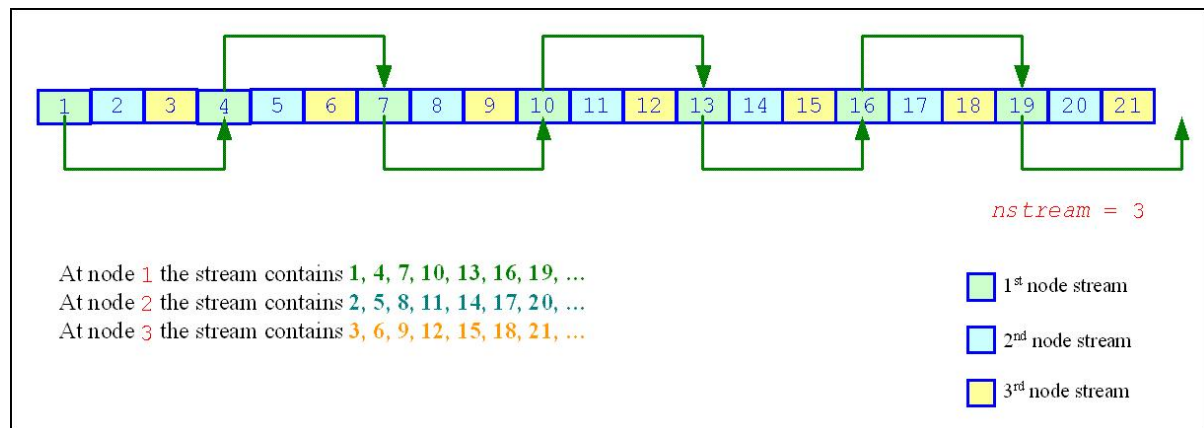

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function function allows generating random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from original stream across *nstreams* buffers without generating the original random sequence with subsequent manual distribution. One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes.

The function initializes the original random stream (see [Figure 10-1](#)) to generate random numbers for the computational node k , $0 \leq k < nstreams$, where $nstreams$ is the largest number of computational nodes used.

Figure 10-1 Leapfrog Method

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VSL Notes](#) for details.

For quasi-random basic generators the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case $nstreams$ parameter should be equal to the dimension of the quasi-random vector while k parameter should be the index of a component to be generated ($0 \leq k < nstreams$). Other parameters values are not allowed.

The following code examples illustrate the initialization of three independent streams using the leapfrog method:

Example 10-1 Fortran 90 Code for Leapfrog Method

```
...  
TYPE(VSL_STREAM_STATE)    ::stream1  
TYPE(VSL_STREAM_STATE)    ::stream2  
TYPE(VSL_STREAM_STATE)    ::stream3  
! Creating 3 identical streams  
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)  
status = vslcopystream(stream2, stream1)  
status = vslcopystream(stream3, stream1)  
! Leapfrogging the streams  
  
status = vslleapfrogstream(stream1, 0, 3)  
status = vslleapfrogstream(stream2, 1, 3)  
status = vslleapfrogstream(stream3, 2, 3)  
! Generating random numbers  
  
...  
! Deleting the streams  
  
status = vsldeletestream(stream1)  
status = vsldeletestream(stream2)  
status = vsldeletestream(stream3)  
...
```

Example 10-2 C Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);
/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);
/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK
VSL_ERROR_NULL_PTR
VSL_ERROR_BAD_STREAM
VSL_ERROR_LEAPFROG_UNSUPPORTED

Indicates no error, execution is successful.
stream is a NULL pointer.
stream is not a valid random stream.
BRNG does not support Leapfrog method.

SkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

Fortran:

```
status = vslskipaheadstream( stream, nskip )
```

C:

```
status = vslSkipAheadStream( stream, nskip);
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	FORTRAN: Descriptor of the stream to which block-splitting method is applied
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	C: Pointer to the stream state structure to which block-splitting method is applied
	C: VSLStreamStatePtr	
<i>nskip</i>	FORTRAN 77: INTEGER*4 nskip(2)	Number of skipped elements
	Fortran 90: INTEGER (KIND=8), INTENT (IN)	
	C: const long long int	

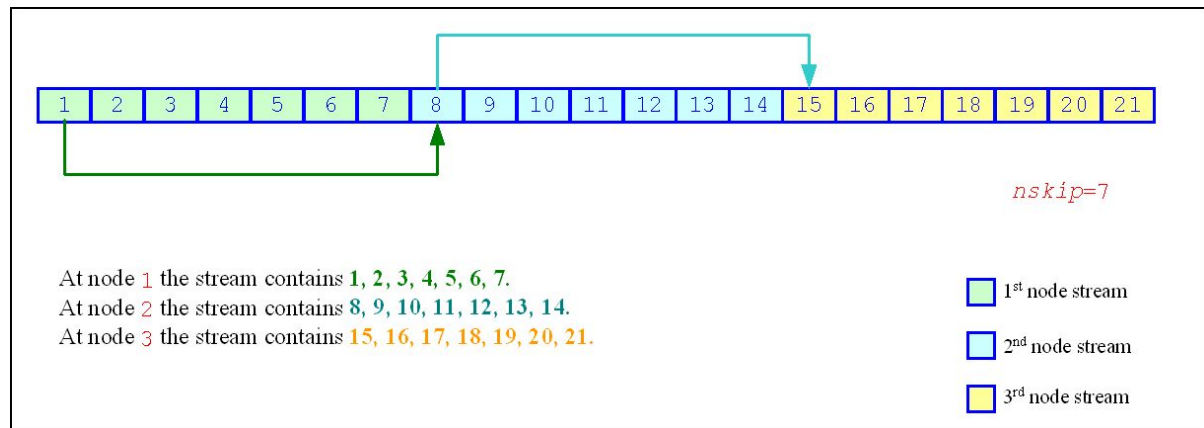

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node

is *nskip*, then the original random sequence may be split by `SkipAheadStream` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see [Figure 10-2](#)).

Figure 10-2 Block-Splitting Method

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VSL Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Thus to skip *NS* quasi-random vectors, set *nskip* parameter equal to the *NS*DIMEN*, where *DIMEN* is the dimension of quasi-random vector.

The following code examples illustrate how to initialize three independent streams using `SkipAheadStream` function:

Example 10-3 Fortran 90 Code for Block-Splitting Method

```
...
type(VSL_STREAM_STATE)  ::stream1
type(VSL_STREAM_STATE)  ::stream2
type(VSL_STREAM_STATE)  ::stream3
! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
! Skipping ahead by 7 elements the 2nd stream

status = vslcopystream(stream2, stream1);
status = vslskipaheadstream(stream2, 7);
! Skipping ahead by 7 elements the 3rd stream

status = vslcopystream(stream3, stream2);
status = vslskipaheadstream(stream3, 7);
! Generating random numbers

...
! Deleting the streams

status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

Example 10-4 C Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);
/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);
/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.

GetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

Fortran:

```
brng = vslgetstreamstatebrng( stream )
```

C:

```
brng = vslGetStreamStateBrng( stream );
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), TINTENT(IN) C: const VSLStreamStatePtr	FORTRAN: Descriptor of the stream state C: Pointer to the stream state structure

Output Parameters

Name	Type	Description
<i>brng</i>	FORTRAN: INTEGER C: int	Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function retrieves the index of a basic generator used for generation of a given random stream.

Return Values

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

GetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

Fortran:

```
nregbrngs = vslgetnumregbrngs( )
```

C:

```
nregbrngs = vslGetNumRegBrngs( void );
```

Output Parameters

Name	Type	Description
<i>nregbrngs</i>	FORTTRAN: INTEGER C: int	Number of basic generators registered at the moment of the function call

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by `VSL_MAX_REG_BRNGS` parameter.

Distribution Generators

VSL routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence for both FORTRAN

and C-interface and the explanation of input and output parameters. [Table 10-8](#) and [Table 10-9](#) list the random number generator routines, together with used data types, output distributions, and sets correspondence between data types of the generator routines and called basic random number generators.

Table 10-8 Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
Uniform	s, d	s, d	Uniform continuous distribution on the interval $[a, b]$.
Gaussian	s, d	s, d	Normal (Gaussian) distribution.
GaussianMV	s, d	s, d	Multivariate normal (Gaussian) distribution.
Exponential	s, d	s, d	Exponential distribution.
Laplace	s, d	s, d	Laplace distribution (double exponential distribution).
Weibull	s, d	s, d	Weibull distribution.
Cauchy	s, d	s, d	Cauchy distribution.
Rayleigh	s, d	s, d	Rayleigh distribution.
Lognormal	s, d	s, d	Lognormal distribution.
Gumbel	s, d	s, d	Gumbel (extreme value) distribution.
Gamma	s, d	s, d	Gamma distribution.
Beta	s, d	s, d	Beta distribution.

Table 10-9 Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
Uniform	i	d	Uniform discrete distribution on the interval $[a, b]$.

Type of Distribution	Data Types	BRNG Data Type	Description
UniformBits	i	i	Generator of integer random values with uniform bit distribution.
Bernoulli	i	s	Bernoulli distribution.
Geometric	i	s	Geometric distribution.
Binomial	i	d	Binomial distribution.
Hypergeometric	i	d	Hypergeometric distribution.
Poisson	i	s (for VSL_METHOD_IPOISSON_POISNORM) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for VSL_METHOD_IPOISSON_PTPE)	Poisson distribution.
PoissonV	i	s	Poisson distribution with varying mean.
NegBinomial	i	d	Negative binomial distribution, or Pascal distribution.

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval $[a,b]$ belong to this interval irrespective of what a and b values may be. Fast mode provides high performance of generation and also guaranties that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Table 10-10 Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
Uniform	s, d
Exponential	s, d
Weibull	s, d
Rayleigh	s, d
Lognormal	s, d
Gamma	s, d
Beta	s, d

See additional details about accurate and fast mode of random number generation in [VSL Notes](#).

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

Uniform

Generates random numbers with uniform distribution.

Syntax

Fortran:

```
status = vsrnguniform( method, stream, n, r, a, b )
status = vdrnguniform( method, stream, n, r, a, b )
```

C:

```
status = vsRngUniform( method, stream, n, r, a, b );
status = vdRngUniform( method, stream, n, r, a, b );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method; the specific values are as follows: VSL_METHOD_SUNIFORM_STD VSL_METHOD_DUNIFORM_STD VSL_METHOD_SUNIFORM_STD_ACCURATE VSL_METHOD_DUNIFORM_STD_ACCURATE Standard method.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL, INTENT (IN) for vsrnguniform DOUBLE PRECISION, INTENT (IN) for vdrnguniform	Left bound a

Name	Type	Description
	C: const float for vsRngUniform const double for vdRngUniform	
<i>b</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL, INTENT(IN) for vsrnguniform DOUBLE PRECISION, INTENT(IN) for vdrnguniform C: const float for vsRngUniform const double for vdRngUniform	Right bound <i>b</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL, INTENT(OUT) for vsrnguniform	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b]$

Name	Type	Description
------	------	-------------

	<code>DOUBLE PRECISION,</code> <code>INTENT (OUT) for</code> <code>vdRngUniform</code> C: <code>float* for</code> <code>vsRngUniform</code> <code>double* for</code> <code>vdRngUniform</code>	
--	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers uniformly distributed over the interval $[a, b]$, where a, b are the left and right bounds of the interval, respectively, and $a, b \in \mathbb{R} ; a > b$.

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \frac{1}{b-a}, & x \in [a, b] \\ 0, & x \notin [a, b] \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$f_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{x-a}{b-a}, & a \leq x \leq b, \\ 1, & x \geq b \end{cases}, \quad -\infty < x < +\infty .$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Gaussian

Generates normally distributed random numbers.

Syntax

Fortran:

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

```
status = vdrnggaussian( method, stream, n, r, a, sigma )
```

C:

```
status = vsRngGaussian( method, stream, n, r, a, sigma );
```

```
status = vdRngGaussian( method, stream, n, r, a, sigma );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SGAUSSIAN_BOXMULLER VSL_METHOD_SGAUSSIAN_BOXMULLER2 VSL_METHOD_SGAUSSIAN_ICDF VSL_METHOD_DGAUSSIAN_BOXMULLER VSL_METHOD_DGAUSSIAN_BOXMULLER2 VSL_METHOD_DGAUSSIAN_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table 10-1
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL, INTENT (IN) for vsrnggaussian	Mean value <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdrnggaussian C: const float for vsRngGaussian const double for vdRngGaussian	
<i>sigma</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL, INTENT(IN) for vsrnggaussian DOUBLE PRECISION, INTENT(IN) for vdrnggaussian C: const float for vsRngGaussian const double for vdRngGaussian	Standard deviation σ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian	Vector of <i>n</i> normally distributed random numbers

Name	Type	Description
	Fortran 90: REAL, INTENT(OUT) for vsrnggaussian	
	DOUBLE PRECISION, INTENT(OUT) for vdrnggaussian	
	C: float* for vsRngGaussian	
	double* for vdRngGaussian	

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates random numbers with normal (Gaussian) distribution with mean value a and standard deviation σ , where

$a, \sigma \in \mathbb{R}$; $\sigma > 0$.

The probability density function is given by:

$$f_{a, \sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a, \sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function $F_{a,\sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$$F_{a,\sigma}(x) = \Phi((x - a)/\sigma)$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

GaussianMV

Generates random numbers from multivariate normal distribution.

Syntax

Fortran:

```
status = vsrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

```
status = vdrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

C:

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

```
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

Input Parameters

Name	Type	Description

Name	Type	Description
	Fortran 90: REAL, INTENT(OUT) for vsrnggaussianmv DOUBLE PRECISION, INTENT(OUT) for vdrnggaussianmv C: float* for vsRngGaussianMV double* for vdRngGaussianMV	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with d -variate normal (Gaussian) distribution with mean value a and variance-covariance matrix C , where $a \in R^d$; C is a $d \times d$ symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x-a)^T C^{-1}(x-a)),$$

where $x \in R^d$.

Matrix C can be represented as $C = TT^T$, where T is a lower triangular matrix - Cholesky factor of C .

Instead of variance-covariance matrix C the generation routines require Cholesky factor of C in input. To compute Cholesky factor of matrix C , the user may call MKL LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV`/`v?rnggaussianmv` routines (`?` means either `s` or `d` for single and double precision respectively). See [Application Notes](#) for more details.

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VSL example file.

Table 10-11 Using Cholesky Factorization Routines in Fortran

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in Fortran two-dimensional array	spotrf for vsrnggaussianmv dpotrf for vdrnggaussianmv	'U'	Upper triangle of T^T . Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsrnggaussianmv dpptrf for vdrnggaussianmv	'L'	Upper triangle of T^T packed by rows into one-dimensional array.

Table 10-12 Using Cholesky Factorization Routines in C

VSL_MATRIX_STORAGE_FULL	C in C two-dimensional array	spotrf for vsRngGaussianMV dpotrf for vdRngGaussianMV	'U'	Upper triangle of T^T . Lower triangle is not used.

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsRngGaussianMV dpptrf for vdRngGaussianMV	'L'	Upper triangle of T^T packed by rows into one-dimensional array.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Exponential

Generates exponentially distributed random numbers.

Syntax

Fortran:

```
status = vsrngexponential( method, stream, n, r, a, beta )
status = vdrngexponential( method, stream, n, r, a, beta )
```

C:

```
status = vsRngExponential( method, stream, n, r, a, beta );
status = vdRngExponential( method, stream, n, r, a, beta );
```

Output Parameters

Name	Type	Description
r	FORTRAN 77: REAL for vsrngexponential DOUBLE PRECISION for vdrngexponential Fortran 90: REAL, INTENT (OUT) for vsrngexponential DOUBLE PRECISION, INTENT (OUT) for vdrngexponential C: float* for vsRngExponential double* for vdRngExponential	Vector of n exponentially distributed random numbers

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with exponential distribution that has displacement a and scalefactor β , where $a, \beta \in R ; \beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp (-(x - a)) / \beta) , & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp(-(x - a) / \beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Laplace

Generates random numbers with Laplace distribution.

Syntax

Fortran:

```
status = vsrnglaplace( method, stream, n, r, a, beta )
```

```
status = vdrnglaplace( method, stream, n, r, a, beta )
```

C:

```
status = vsRngLaplace( method, stream, n, r, a, beta );
```

```
status = vdRngLaplace( method, stream, n, r, a, beta );
```

Input Parameters

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN 77: REAL for vsrnglaplace DOUBLE PRECISION for vdrnglaplace Fortran 90: REAL, INTENT(OUT) for vsrnglaplace DOUBLE PRECISION, INTENT(OUT) for vdrnglaplace	Vector of n Laplace distributed random numbers

Name	Type	Description
	C: float* for vsRngLaplace	
	double* for vdRngLaplace	

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates random numbers with Laplace distribution with mean value (or average) a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$. The scalefactor value determines the standard deviation as

$$\sigma = \beta\sqrt{2}$$

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x-a|}{\beta}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, \quad -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Weibull

Generates Weibull distributed random numbers.

Syntax

Fortran:

```
status = vsrngweibull( method, stream, n, r, alpha, a, beta )
status = vdrngweibull( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngWeibull( method, stream, n, r, alpha, a, beta );
status = vdRngWeibull( method, stream, n, r, alpha, a, beta );
```

Input Parameters

	DOUBLE PRECISION, INTENT(OUT) for vdrngweibull	
	C: float* for vsRngWeibull	
	double* for vdRngWeibull	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates Weibull distributed random numbers with displacement a , scalefactor β , and shape α , where $\alpha, \beta, a \in \mathbb{R}$; $\alpha > 0, \beta > 0$.

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x-a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Cauchy

Generates Cauchy distributed random values.

Syntax

Fortran:

```
status = vsrngcauchy( method, stream, n, r, a, beta )
```

```
status = vdrngcauchy( method, stream, n, r, a, beta )
```

C:

```
status = vsRngCauchy( method, stream, n, r, a, beta );
```

```
status = vdRngCauchy( method, stream, n, r, a, beta );
```

Input Parameters

Name	Type	Description
------	------	-------------

	double* for vdRngCauchy	
--	-------------------------	--

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi`

The function generates Cauchy distributed random numbers with displacement a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta \left(1 + \left(\frac{x-a}{\beta} \right)^2 \right)}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan \left(\frac{x-a}{\beta} \right), -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Rayleigh

Generates Rayleigh distributed random values.

Syntax

Fortran:

```
status = vsrnggrayleigh( method, stream, n, r, a, beta )
status = vdrngrgrayleigh( method, stream, n, r, a, beta )
```

C:

```
status = vsRngRayleigh( method, stream, n, r, a, beta );
status = vdRngRayleigh( method, stream, n, r, a, beta );
```

Input Parameters

Output Parameters

Name	Type	Description
r	FORTRAN 77: REAL for vsrngrayleigh DOUBLE PRECISION for vdrngrayleigh Fortran 90: REAL, INTENT(OUT) for vsrngrayleigh DOUBLE PRECISION, INTENT(OUT) for vdrngrayleigh C: float* for vsRngRayleigh double* for vdRngRayleigh	Vector of n Rayleigh distributed random numbers

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates Rayleigh distributed random numbers with displacement a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$.

Rayleigh distribution is a special case of [Weibull](#) distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Lognormal

Generates lognormally distributed random numbers.

Syntax

Fortran:

```
status = vsrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

```
status = vdrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

C:

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

```
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

<i>r</i>	FORTTRAN 77: REAL for vsrnglognormal DOUBLE PRECISION for vdrnglognormal Fortran 90: REAL, INTENT(OUT) for vsrnglognormal DOUBLE PRECISION, INTENT(OUT) for vdrnglognormal	Vector of n lognormally distributed random numbers

Name	Type	Description
	C: float* for vsRngLognormal	
	double* for vdRngLognormal	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates lognormally distributed random numbers with average of distribution a and standard deviation σ of subject normal distribution, displacement b , and scalefactor β , where $a, \sigma, b, \beta \in R ; \sigma > 0, \beta > 0$.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x-b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi((\ln((x-b)/\beta) - a)/\sigma), & x > b \\ 0, & x \leq b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Gumbel

Generates Gumbel distributed random values.

Syntax

Fortran:

```
status = vsrnggumbel( method, stream, n, r, a, beta )
status = vdrnggumbel( method, stream, n, r, a, beta )
```

C:

```
status = vsRngGumbel( method, stream, n, r, a, beta );
status = vdRngGumbel( method, stream, n, r, a, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER	Generation method. The specific values are as follows: VSL_METHOD_SGUMBEL_ICDF VSL_METHOD_DGUMBEL_ICDF Inverse cumulative distribution function method
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>stream</i>	FORTRAN 77: INTEGER*4	FORTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure
	stream(2)	
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	
	C: VSLStreamStatePtr	

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: REAL for vsrnggumbel DOUBLE PRECISION for vdrnggumbel Fortran 90: REAL, INTENT (IN) for vsrnggumbel DOUBLE PRECISION, INTENT (IN) for vdrnggumbel C: const float for vsRngGumbel const double for vdRngGumbel	Displacement <i>a</i> .
<i>beta</i>	FORTRAN 77: REAL for vsrnggumbel DOUBLE PRECISION for vdrnggumbel Fortran 90: REAL, INTENT (IN) for vsrnggumbel DOUBLE PRECISION, INTENT (IN) for vdrnggumbel C: const float for vsRngGumbel	Scalefactor β .

Name	Type	Description
	<code>const double for vdRngGumbel</code>	

Output Parameters

Name	Type	Description
<i>r</i>	<p>FORTRAN 77: REAL for <code>vsrnggumbel</code></p> <p>DOUBLE PRECISION for <code>vdrnggumbel</code></p> <p>Fortran 90: REAL, INTENT (OUT) for <code>vsrnggumbel</code></p> <p>DOUBLE PRECISION, INTENT (OUT) for <code>vdrnggumbel</code></p> <p>C: <code>float*</code> for <code>vsRngGumbel</code> <code>double*</code> for <code>vdRngGumbel</code></p>	Vector of <i>n</i> random numbers with Gumbel distribution

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates Gumbel distributed random numbers with displacement *a* and scalefactor *β*, where *a*, *β* ∈ *R* ; *β* > 0.

The probability density function is given by:

$$f_{a,\beta}(x) = \left\{ \frac{1}{\beta} \exp \left(\frac{x - a}{\beta} \right) \exp (- \exp ((x - a) / \beta)) \right\}, \quad - \infty < x < +\infty .$$

The cumulative distribution function is as follows:

$$F_{\alpha,\beta}(x) = 1 - \exp(-\exp((x - \alpha) / \beta)), -\infty < x < +\infty$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Gamma

Generates gamma distributed random values.

Syntax

Fortran:

```
status = vsrnggamma( method, stream, n, r, alpha, a, beta )
status = vdrnggamma( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngGamma( method, stream, n, r, alpha, a, beta );
status = vdRngGamma( method, stream, n, r, alpha, a, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SGAMMA_GNORM VSL_METHOD_DGAMMA_GNORM VSL_METHOD_SGAMMA_GNORM_ACCURATE VSL_METHOD_DGAMMA_GNORM_ACCURATE Acceptance/rejection method using random numbers with Gaussian distribution. See brief description of the method GNORM in Table 10-1
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure

<i>alpha</i>	FORTRAN 77: REAL for vsrnggamma DOUBLE PRECISION for vdrnggamma Fortran 90: REAL, INTENT (IN) for vsrnggamma DOUBLE PRECISION, INTENT (IN) for vdrnggamma	Shape α .

Name	Type	Description
	C: const float for vsRngGamma const double for vdRngGamma	
<i>a</i>	FORTRAN 77: REAL for vsrnggamma DOUBLE PRECISION for vdrnggamma Fortran 90: REAL, INTENT (IN) for vsrnggamma DOUBLE PRECISION, INTENT (IN) for vdrnggamma C: const float for vsRngGamma const double for vdRngGamma	Displacement <i>a</i> .
<i>beta</i>	FORTRAN 77: REAL for vsrnggamma DOUBLE PRECISION for vdrnggamma Fortran 90: REAL, INTENT (IN) for vsrnggamma DOUBLE PRECISION, INTENT (IN) for vdrnggamma C: const float for vsRngGamma const double for vdRngGamma	Scalefactor β .

Output Parameters

Name	Type	Description
r	FORTRAN 77: REAL for vsrnggamma DOUBLE PRECISION for vdrnggamma Fortran 90: REAL, INTENT (OUT) for vsrnggamma DOUBLE PRECISION, INTENT (OUT) for vdrnggamma C: float* for vsRngGamma double* for vdRngGamma	Vector of n random numbers with gamma distribution

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with gamma distribution that has shape parameter α , displacement a , and scale parameter β , where α, β , and $a \in \mathbb{R}$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha,a,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x-a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where $\Gamma(\alpha)$ is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha, a, \beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y-a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Beta

Generates beta distributed random values.

Syntax

Fortran:

```
status = vsrngbeta( method, stream, n, r, p, q, a, beta )
```

```
status = vdrngbeta( method, stream, n, r, p, q, a, beta )
```

C:

```
status = vsRngBeta( method, stream, n, r, p, q, a, beta );
```

```
status = vdRngBeta( method, stream, n, r, p, q, a, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SBETA_CJA VSL_METHOD_DBETA_CJA VSL_METHOD_SBETA_CJA_ACCURATE VSL_METHOD_DBETA_CJA_ACCURATE See brief description of the method CJA in Table 10-1
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure

Name	Type	Description
<i>beta</i>	FORTRAN 77: REAL for vsrngbeta DOUBLE PRECISION for vdrngbeta Fortran 90: REAL, INTENT (IN) for vsrngbeta DOUBLE PRECISION, INTENT (IN) for vdrngbeta C: const float for vsRngBeta const double for vdRngBeta	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrngbeta DOUBLE PRECISION for vdrngbeta Fortran 90: REAL, INTENT (OUT) for vsrngbeta DOUBLE PRECISION, INTENT (OUT) for vdrngbeta C: float* for vsRngBeta double* for vdRngBeta	Vector of n random numbers with beta distribution

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi`

The function generates random numbers with beta distribution that has shape parameters p and q , displacement a , and scale parameter β , where p, q, a , and $\beta \in \mathbb{R}$; $p > 0$, $q > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p, q)\beta^{p+q-1}} (x-a)^{p-1}(\beta+a-x)^{q-1}, & a \leq x < a + \beta \\ 0, & x < a, x \geq a + \beta \end{cases}, -\infty < x < \infty,$$

where $B(p, q)$ is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p, q)\beta^{p+q-1}} (y-a)^{p-1}(\beta+a-y)^{q-1} dy, & a \leq x < a + \beta \\ 1, & x \geq a + \beta \end{cases}, -\infty < x < \infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

Uniform

Generates random numbers uniformly distributed over the interval $[a, b)$.

Syntax

Fortran:

```
status = virnguniform( method, stream, n, r, a, b )
```

C:

```
status = viRngUniform( method, stream, n, r, a, b );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method; dummy and set to 0 in case of uniform distribution. The specific value is as follows: VSL_METHOD_IUNIFORM_STD Standard method. Currently there is only one method for this distribution generator.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated

Name	Type	Description
a	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Left interval bound a
b	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Right interval bound b

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n random numbers uniformly distributed over the interval $[a, b)$

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers uniformly distributed over the interval $[a, b)$, where a, b are the left and right bounds of the interval respectively, and $a, b \in \mathbb{Z}; a < b$.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in R. \\ 1, & x \geq b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

UniformBits

Generates integer random values with uniform bit distribution.

Syntax

Fortran:

```
status = virnguniformbits( method, stream, n, r )
```

C:

```
status = viRngUniformBits( method, stream, n, r );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method; dummy and set to 0. The specific value is as follows: VSL_METHOD_IUNIFORMBITS_STD Standard method. Currently there is only one method for this distribution generator.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: unsigned int*	FORTRAN: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>wordsize</i> of the structure VSL_BRNG_PROPERTIES. The total number of bits that are actually used to store the value are contained in the field <i>nbits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties.

Name	Type	Description
		C: Vector of n random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of r respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure <code>VSLBRngProperties</code> . The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of <code>VSLBRngProperties</code> .

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit *LCG* only 24 higher bits of an integer value can be considered random. See [VSL Notes](#) for details.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Bernoulli

Generates Bernoulli distributed random values.

Syntax

Fortran:

```
status = virngbernoulli( method, stream, n, r, p )
```

C:

```
status = viRngBernoulli( method, stream, n, r, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER	Generation method. The specific value is as follows:
	Fortran 90: INTEGER, INTENT (IN)	VSL_METHOD_IBERNOULLI_ICDF
	C: const int	Inverse cumulative distribution function method.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	FORTRAN: Descriptor of the stream state structure.
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	C: Pointer to the stream state structure
	C: VSLStreamStatePtr	
<i>n</i>	FORTRAN 77: INTEGER	Number of random values to be generated
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>p</i>	FORTRAN 77: DOUBLE PRECISION	Success probability p of a trial
	Fortran 90: DOUBLE PRECISION, INTENT (IN)	

Name	Type	Description
	C: const double	

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n Bernoulli distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates Bernoulli distributed random numbers with probability p of a single trial success, where

$$p \in \mathbb{R}; \quad 0 \leq p \leq 1.$$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success p , and to 0 with probability $1 - p$.

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in \mathbb{R}. \\ 1, & x \geq 1 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Geometric

Generates geometrically distributed random values.

Syntax

Fortran:

```
status = virnggeometric( method, stream, n, r, p )
```

C:

```
status = viRngGeometric( method, stream, n, r, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER	Generation method. The specific value is as follows:
	Fortran 90: INTEGER, INTENT (IN)	VSL_METHOD_IGEOMETRIC_ICDF
	C: const int	Inverse cumulative distribution function method.
<i>stream</i>	FORTRAN 77: INTEGER*4	FORTRAN: Descriptor of the stream state structure.
	stream(2)	C: Pointer to the stream state structure
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	

Name	Type	Description
	C: VSLStreamStatePtr	
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
p	FORTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Success probability p of a trial

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n geometrically distributed random values

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates geometrically distributed random numbers with probability p of a single trial success, where $p \in R$; $0 < p < 1$.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is p .

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, \quad k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \leq x \end{cases} \quad x \in R.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Binomial

Generates binomially distributed random numbers.

Syntax

Fortran:

```
status = virngbinomial( method, stream, n, r, ntrial, p )
```

C:

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Generation method. The specific value is as follows: VSL_METHOD_IBINOMIAL_BTPE

Name	Type	Description
	C: <code>const int</code>	See brief description of the BTPE method in Table 10-1 .
<i>stream</i>	FORTRAN 77: <code>INTEGER*4</code> <code>stream(2)</code> Fortran 90: <code>TYPE</code> <code>(VSL_STREAM_STATE),</code> <code>INTENT (IN)</code> C: <code>VSLStreamStatePtr</code>	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: <code>INTEGER</code> Fortran 90: <code>INTEGER,</code> <code>INTENT (IN)</code> C: <code>const int</code>	Number of random values to be generated
<i>ntrials</i>	FORTRAN 77: <code>INTEGER</code> Fortran 90: <code>INTEGER,</code> <code>INTENT (IN)</code> C: <code>const int</code>	Number of independent trials m
<i>p</i>	FORTRAN 77: <code>DOUBLE</code> <code>PRECISION</code> Fortran 90: <code>DOUBLE</code> <code>PRECISION, INTENT (IN)</code> C: <code>const double</code>	Success probability p of a single trial

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: <code>INTEGER</code> Fortran 90: <code>INTEGER,</code> <code>INTENT (OUT)</code>	Vector of n binomially distributed random values

Name	Type	Description
------	------	-------------

	C: int*	
--	----------------	--

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates binomially distributed random numbers with number of independent Bernoulli trials m , and with probability p of a single trial success, where $p \in R$; $0 \leq p \leq 1$, $m \in N$.

A binomially distributed variate represents the number of successes in m independent Bernoulli trials with probability of a single trial success p .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1 - p)^{m-k}, & 0 \leq x < m, x \in R \\ 1, & x \geq m \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Hypergeometric

Generates hypergeometrically distributed random values.

Syntax

Fortran:

```
status = virnghypergeometric( method, stream, n, r, l, s, m )
```

C:

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific value is as follows: VSL_METHOD_IHYPERGEOMETRIC_H2PE See brief description of the H2PE method in Table 10-1
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
l	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Lot size l
s	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of sampling without replacement s
m	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of marked elements m

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n hypergeometrically distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates hypergeometrically distributed random values with lot size l , size of sampling s , and number of marked elements in the lot m , where $l, m, s \in \mathbb{N} \cup \{0\}$; $l \geq \max(s, m)$.

Consider a lot of l elements comprising m “marked” and $l-m$ “unmarked” elements. A trial sampling without replacement of exactly s elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of s elements contains exactly k marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

, $k \in \{\max(0, s + m - l), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0, s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s + m - l) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

VSL_ERROR_NULL_PTR

VSL_ERROR_BAD_STREAM

VSL_ERROR_BAD_UPDATE

Indicates no error, execution is successful.

stream is a NULL pointer.

stream is not a valid random stream.

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Poisson

Generates Poisson distributed random values.

Syntax

Fortran:

`status = virngpoisson(method, stream, n, r, lambda)`

C:

`status = viRngPoisson(method, stream, n, r, lambda);`

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_IPOISSON_PTPE VSL_METHOD_IPOISSON_POISNORM See brief description of the PTPE and POISNORM methods in Table 10-1 .
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated

Name	Type	Description
<i>lambda</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Distribution parameter λ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n Poisson distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates Poisson distributed random numbers with distribution parameter λ , where $\lambda \in R$; $\lambda > 0$.

The probability distribution is given by:

$$P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!},$$

$k \in \{0, 1, 2, \dots\}$.

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

PoissonV

Generates Poisson distributed random values with varying mean.

Syntax

Fortran:

```
status = virngpoissonv( method, stream, n, r, lambda )
```

C:

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Generation method. The specific value is as follows: VSL_METHOD_IPOISSONV_POISNORM

Name	Type	Description
	C: <code>const int</code>	See brief description of the <code>POISNORM</code> method in Table 10-1
<i>stream</i>	FORTRAN 77: <code>INTEGER*4</code> <code>stream(2)</code> Fortran 90: <code>TYPE</code> <code>(VSL_STREAM_STATE),</code> <code>INTENT (IN)</code> C: <code>VSLStreamStatePtr</code>	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: <code>INTEGER</code> Fortran 90: <code>INTEGER,</code> <code>INTENT (IN)</code> C: <code>const int</code>	Number of random values to be generated
<i>lambda</i>	FORTRAN 77: <code>DOUBLE</code> <code>PRECISION</code> Fortran 90: <code>DOUBLE</code> <code>PRECISION, INTENT (IN)</code> C: <code>const double*</code>	Array of <i>n</i> distribution parameters λ_i .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: <code>INTEGER</code> Fortran 90: <code>INTEGER,</code> <code>INTENT (OUT)</code> C: <code>int*</code>	Vector of <i>n</i> Poisson distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates n Poisson distributed random numbers $x_i (i = 1, \dots, n)$ with distribution parameter λ_i , where $\lambda_i \in R; \lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

NegBinomial

Generates random numbers with negative binomial distribution.

Syntax

Fortran:

```
status = virngnegbinomial( method, stream, n, r, a, p )
```

C:

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific value is: VSL_METHOD_INEGBINOMIAL_NBAR See brief description of the NBAR method in Table 10-1
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: descriptor of the stream state structure. C: pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: DOUBLE PRECISION	The first distribution parameter <i>a</i>

Name	Type	Description
	Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	
p	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	The second distribution parameter p

Output Parameters

Name	Type	Description
r	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n random values with negative binomial distribution.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with negative binomial distribution and distribution parameters a and p , where $p, a \in R; 0 < p < 1; a > 0$.

If the first distribution parameter $a \in N$, this distribution is the same as Pascal distribution. If $a \in N$, the distribution can be interpreted as the expected time of a -th success in a sequence of Bernoulli trials, when the probability of success is p .

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^k p^a (1-p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Advanced Service Routines

This section describes service routines for registering a user-designed basic generator ([RegisterBrng](#)) and for obtaining properties of the previously registered basic generators ([GetBrngProperties](#)). See [VSL Notes](#) ("Basic Generators" section of VSL Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

Data types

The Advanced Service routines refer to a structure defining the properties of the basic generator. This structure is described in Fortran 90 as follows:

```
TYPE VSL_BRNG_PROPERTIES
    INTEGER streamstatesize
    INTEGER nseeds
    INTEGER includeszero
    INTEGER wordsize
    INTEGER nbits
    INTEGER nitstream
    INTEGER sbrng
    INTEGER dbrng
    INTEGER ibrng
END TYPE VSL_BRNG_PROPERTIES
```

The C version is as follows:

```
typedef struct _VSLBRngProperties {
    int StreamStateSize;
    int NSeeds;
    int IncludesZero;
    int WordSize;
    int NBits;
    InitStreamPtr InitStream;
    sBRngPtr sBRng;
    dBRngPtr dBRng;
    iBRngPtr iBRng;
} VSLBRngProperties;
```

The following table provides brief descriptions of the fields engaged in the above structure:

Table 10-13 Field Descriptions

Field	Short Description
FORTTRAN: <code>streamstatesize</code> C: <code>StreamStateSize</code>	The size, in bytes, of the stream state structure for a given basic generator.
FORTTRAN: <code>nseeds</code> C: <code>NSeeds</code>	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
FORTTRAN: <code>includeszero</code> C: <code>IncludesZero</code>	Flag value indicating whether the generator can produce a random 0.
FORTTRAN: <code>wordsize</code> C: <code>WordSize</code>	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
FORTTRAN: <code>nbits</code> C: <code>NBits</code>	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, <code>wordsize/WordSize</code> is equal to 8 (number of bytes used to store the random value), while <code>nbits/NBits</code> contains the actual number of bits occupied by the value (in this example, 48).
FORTTRAN: <code>initstream</code> C: <code>InitStream</code>	Contains the pointer to the initialization routine of a given basic generator.
FORTTRAN: <code>sbrng</code> C: <code>sBRng</code>	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval (a,b) (<code>real</code> in FORTRAN and <code>float</code> in C).
FORTTRAN: <code>dbrng</code> C: <code>dBRng</code>	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval (a,b) (<code>double PRECISION</code> in FORTRAN and <code>double</code> in C).
FORTTRAN: <code>ibrng</code> C: <code>iBRng</code>	Contains the pointer to the basic generator of integer numbers with uniform bit distribution ¹ (<code>INTEGER</code> in FORTRAN and <code>unsigned int</code> in C).

¹A specific generator that permits operations over single bits and bit groups of random numbers.

RegisterBrng

Registers user-defined basic generator.

Syntax

Fortran:

```
brng = vslregisterbrng( properties )
```

C:

```
brng = vslRegisterBrng( &properties );
```

Input Parameters

Name	Type	Description
<i>properties</i>	FORTTRAN: TYPE (VSL_BRNG_PROPERTIES), INTENT (IN) C: const VSLBRngProperties*	Pointer to the structure containing properties of the basic generator to be registered

NOTE. FORTRAN 77 support is unavailable for this function.

Output Parameters

Name	Type	Description
<i>brng</i>	FORTTRAN: INTEGER, INTENT (OUT) C: int	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

Description

This function is declared in `mkl_vsl.fi` for Fortran 90 interface and in `mkl_vsl_functions.h` for C interface.

An example of a registration procedure can be found in the respective directory of VSL examples.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_ERROR_BAD_STREAM_STATE_SIZE	Bad value in StreamStateSize field.
VSL_ERROR_BAD_WORD_SIZE	Bad value in WordSize field.
VSL_ERROR_BAD_NSEEDS	Bad value in NSeeds field.
VSL_ERROR_BAD_NBITS	Bad value in NBits field.
VSL_ERROR_NULL_PTR	At least one of the fields iBrng, dBrng, sBrng or InitStream is a NULL pointer.

GetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

Fortran:

```
status = vslgetbrngproperties( brng, properties )
```

C:

```
status = vslGetBrngProperties( brng, &properties );
```

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN: INTEGER, INTENT (IN) C: const int	Number (index) of the registered basic generator; used for identification. See specific values in Table 10-2 . Negative values indicate the registration error.

NOTE. FORTRAN 77 support is unavailable for this function.

Output Parameters

Name	Type	Description
<i>properties</i>	FORTRAN: TYPE (VSL_BRNG_PROPERTIES), INTENT (OUT) C: VSLBRngProperties*	Pointer to the structure containing properties of the generator with number <i>brng</i>

Description

This function is declared in `mkl_vsl.fi` for Fortran 90 interface and in `mkl_vsl_functions.h` for C interface.

The function returns a structure with properties of a given basic generator.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.

Formats for User-Designed Generators

To register a user-designed basic generator using `RegisterBrng` function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See below recommendations on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VSL examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] );

typedef int(*sBrngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );

typedef int(*dBrngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );

typedef int(*iBrngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

InitStream

C:

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int
params[] )
{
    /* Initialize the stream */
    ...
} /* MyBrngInitStream */
```

Description

The initialization routine of a user-designed generator must initialize *stream* according to the specified initialization *method*, initial conditions *params* and the argument *n*. The value of *method* determines the initialization method to be used.

- If *method* is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.
- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_ERROR_SKIPAHEAD_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of [LeapfrogStream](#) and [SkipAheadStream](#), respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

C:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;
- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in $LCG(a, c, m)$, apart from the initial conditions, two more fields should be specified: the value of the multiplier a^k and the value of the increment $(a^k - 1) c / (a - 1)$.

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VSL examples.

iBRng

C:

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
    store only random number */
    for( i = 0; i < n; i++)
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* iMyBrng */
```

NOTE. When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector x correctly. For example, storing one 64-bit value requires two elements of x , the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of x to store a 128-bit value.

sBRng

C:

```
int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int i;    /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */
```

dBRng

C:

```
int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i;    /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */
```

Convolution and Correlation

Overview

VSL provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see [Mathematical Notation and Definitions](#) section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM* ESSL library:

SCONF, SCORF

SCOND, SCORD

SDCON, SDCOR

DDCON, DDCOR

SDDCON, SDDCOR.

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources for FORTRAN and C. To reuse them, use the following directories:

```
${MKL}/examples/vslc/essl/vsl_wrappers
```

```
${MKL}/examples/vslf/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers. You can find the examples in the following directories:

```
${MKL}/examples/vslc/essl
```

```
${MKL}/examples/vslf/essl
```

Convolution and correlation API provides interfaces for FORTRAN 77, Fortran 90 and C/89 languages. You may use the C/89 interface also with later versions of C or C++, or Fortran 90 interface with programs written in Fortran 95.

For users of the C/C++ and FORTRAN languages, the `mkl_vsl.h`, `mkl_vsl.fi`, and `mkl_vsl.f77` headers are provided. All header files are found under the directory:

```
${MKL}/include
```

See more details about the FORTRAN header in [Random Number Generators](#) section of this chapter.

Convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All Intel MKL convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Naming Conventions

The names of FORTRAN routines in the convolution and correlation API are written in lowercase, while the names of FORTRAN types and constants are written in uppercase. The names are not case-sensitive.

In C, the names of routines, types, and constants are case-sensitive and can be lowercase and uppercase.

The names of routines have the following structure:

`vsl[datatype]{Conv|Corr}<base name>` for C-interface

`vsl[datatype]{conv|corr}<base name>` for FORTRAN-interface

where `vsl` is a prefix indicating that the routine belongs to Vector Statistical Library of Intel® MKL.

The field `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).

The prefix `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.

The `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

NOTE. In this document, routines are often referred to by their base name when this does not lead to ambiguity. In the routine reference, the full name is always used in prototypes and code examples.

Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
FORTRAN 77: <code>INTEGER*4</code> <code>task (2)</code>	Pointer to a task descriptor for convolution
Fortran 90: <code>TYPE (VSL_CONV_TASK)</code> C: <code>VSLConvTaskPtr</code>	
FORTRAN 77: <code>INTEGER*4</code> <code>task (2)</code>	Pointer to a task descriptor for correlation
Fortran 90: <code>TYPE (VSL_CORR_TASK)</code> C: <code>VSLCorrTaskPtr</code>	

Type	Data Object
FORTTRAN 77: REAL*4 Fortran 90: REAL (KIND=4) C: float	Input/output user real data in single precision
FORTTRAN 77: REAL*8 Fortran 90: REAL (KIND=8) C: double	Input/output user real data in double precision
FORTTRAN 77: COMLEX*8 Fortran 90: COMPLEX (KIND=4) C: MKL_Complex8	Input/output user complex data in single precision
FORTTRAN 77: COMPLEX*16 Fortran 90: COMPLEX (KIND=8) C: MKL_Complex16	Input/output user complex data in double precision
FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	All other data

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE. The actual size of the generic integer type is platform-dependent. The appropriate byte size for integers must be chosen at the stage of compiling your software.

Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

Table 10-14 Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
<i>job</i>	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
<i>type</i>	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
<i>precision</i>	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays <i>x</i> , <i>y</i> , <i>z</i> .
<i>kind</i>	optional	integer	"linear"	Specifies whether the task relates to computing linear or circular convolution/correlation. Note that currently only the linear type is supported.
<i>mode</i>	explicit	integer	None	Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See SetMode for the list of named constants for this parameter.
<i>method</i>	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.

Name	Category	Type	Default Value Label	Description
<i>internal_precision</i>	optional	integer	Set equal to the value of <i>precision</i>	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See SetInternalPrecision for the list of named constants for this parameter.
<i>dims</i>	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays <i>x,y,z</i> . Can be in the range from 1 to 7.
<i>x,y</i>	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.
<i>z</i>	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
<i>xshape, yshape, zshape</i>	explicit	integer arrays	None	Define shapes of the arrays <i>x, y, z</i> . See Data Allocation for more information.
<i>xstride, ystride, zstride</i>	explicit	integer arrays	None	Define strides within arrays <i>x, y, z</i> , that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.
<i>start</i>	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See SetStart and Data Allocation for more information.
<i>decimation</i>	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See SetDecimation and Data Allocation for more information.

Users of the C or C++ language may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the FORTRAN-style “by columns” representation of multi-dimensional arrays.

Task Status and Error Reporting

Task status is an integer value which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values are used for errors, and positive values are reserved for warnings.

An error can be caused by bad parameter values, system fault like memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor will be terminated and the task will keep the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The status codes are given symbolic names defined in the respective header files. For C/C++, these names are defined as macros via `#define` statements, and for FORTRAN as integer constants via `PARAMETER` operators.

If there is no error, the `VSL_STATUS_OK` is returned, which is defined as zero:

```
C/C++:           #define VSL_STATUS_OK 0
F90/F95:          INTEGER(KIND=4) VSL_STATUS_OK
                  PARAMETER(VSL_STATUS_OK = 0)

F77:              INTEGER*4 VSL_STATUS_OK
                  PARAMETER(VSL_STATUS_OK = 0)
```

In case of an error, a non-zero error code is returned, which signals about the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files for both C/C++ and FORTRAN languages.

Table 10-15 Convolution/Correlation Status Codes and Messages

Status Code	Message
VSL_CC_ERROR_NOT_IMPLEMENTED,	Requested functionality is not implemented.
VSL_CC_ERROR_ALLOCATION_FAILURE	Memory allocation failure.
VSL_CC_ERROR_BAD_DESCRIPTOR	Task descriptor is corrupted.
VSL_CC_ERROR_SERVICE_FAILURE	A service function has failed.
VSL_CC_ERROR_EDIT_FAILURE	Failure while editing the task.
VSL_CC_ERROR_EDIT_PROHIBITED	You cannot edit this parameter.
VSL_CC_ERROR_COMMIT_FAILURE	Task commitment has failed.
VSL_CC_ERROR_COPY_FAILURE	Failure while copying the task.
VSL_CC_ERROR_DELETE_FAILURE	Failure while deleting the task.
VSL_CC_ERROR_BAD_ARGUMENT	Bad argument or task parameter.
VSL_CC_ERROR_JOB	Bad parameter: <i>job</i> .
SL_CC_ERROR_KIND	Bad parameter: <i>kind</i> .
VSL_CC_ERROR_MODE	Bad parameter: <i>mode</i> .
VSL_CC_ERROR_METHOD	Bad parameter: <i>method</i> .
VSL_CC_ERROR_TYPE	Bad parameter: <i>type</i> .
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: <i>external_precision</i> .
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: <i>internal_precision</i> .
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: <i>dims</i> .
VSL_CC_ERROR_XSHAPE	Bad parameter: <i>xshape</i> .
VSL_CC_ERROR_YSHAPE	Bad parameter: <i>yshape</i> .

Status Code	Message
	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_CC_ERROR_ZSHAPE	Bad parameter: <i>zshape</i> .
VSL_CC_ERROR_XSTRIDE	Bad parameter: <i>xstride</i> .
VSL_CC_ERROR_YSTRIDE	Bad parameter: <i>ystride</i> .
VSL_CC_ERROR_ZSTRIDE	Bad parameter: <i>zstride</i> .
VSL_CC_ERROR_X	Bad parameter: <i>x</i> .
VSL_CC_ERROR_Y	Bad parameter: <i>y</i> .
VSL_CC_ERROR_Z	Bad parameter: <i>z</i> .
VSL_CC_ERROR_START	Bad parameter: <i>start</i> .
VSL_CC_ERROR_DECIMATION	Bad parameter: <i>decimation</i> .
VSL_CC_ERROR_OTHER	Some other error.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. This means that no additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form but also assign particular data to the first operand vector used in convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

For each constructor routine there is also an associated one-dimensional version which exploits the algorithmic and computational benefits provided by the simplicity of the data structures for one-dimensional case.

NOTE. If constructor fails to create a task descriptor, it returns `NULL` task pointer.

The [Table 10-16](#) lists available task constructors:

Table 10-16 Task Constructors

Routine	Description
NewTask	Creates a new convolution or correlation task descriptor for a multidimensional case.
NewTask1D	Creates a new convolution or correlation task descriptor for a one-dimensional case.
NewTaskX	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
NewTaskX1D	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

NewTask

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslcconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsllcorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldcorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslccorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzcorrnewtask(task, mode, dims, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsllCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>const int</code>	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>dims</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>const int</code>	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
<i>xshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: <code>const int[]</code>	Defines the shape of the input data for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: <code>const int[]</code>	Defines the shape of the input data for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: <code>const int[]</code>	Defines the shape of the output data to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 <code>task(2)</code> for <code>vslsconvnewtask,</code>	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	vsldconvnewtask, vslcconvnewtask, vslzconvnewtask INTEGER*4 task(2) for vsldcorrnewtask, vsldcorrnewtask, vslccorrnewtask, vslzcorrnewtask Fortran 90: TYPE(VSL_CONV_TASK) for vsldconvnewtask, vsldconvnewtask, vslcconvnewtask, vslzconvnewtask TYPE(VSL_CORR_TASK) for vsldcorrnewtask, vsldcorrnewtask, vslccorrnewtask, vslzcorrnewtask C: VSLConvTaskPtr* for vsldConvNewTask, vsldConvNewTask, vslcConvNewTask, vslzConvNewTask VSLCorrTaskPtr* for vsldCorrNewTask, vsldCorrNewTask, vslcConvNewTask, vslzConvNewTask	
status	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each `NewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a `NULL` task pointer.

NewTask1D

Creates a new convolution or correlation task descriptor for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslcconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslscorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldcorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslccorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzcorrnewtask1d(task, mode, xshape, yshape, zshape)
```

C:

```
status = vs1sConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1dConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1cConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1zConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1sCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1dCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1cCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1zCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>xshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the input data sequence for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the input data sequence for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the output data sequence to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslsconvnewtaskld, vsldconvnewtaskld, vslcconvnewtaskld, vslzconvnewtaskld INTEGER*4 task(2) for vslscorrnewtaskld, vsldcorrnewtaskld, vslccorrnewtaskld, vslzcorrnewtaskld Fortran 90: TYPE (VSL_CONV_TASK) for vslsconvnewtaskld, vsldconvnewtaskld, vslcconvnewtaskld, vslzconvnewtaskld TYPE (VSL_CORR_TASK) for vslscorrnewtaskld, vsldcorrnewtaskld, vslccorrnewtaskld, vslzcorrnewtaskld C: VSLConvTaskPtr* for vslsConvNewTaskld, vsldConvNewTaskld, vslcConvNewTaskld, vslzConvNewTaskld VSLCorrTaskPtr* for vslsCorrNewTaskld, vsldCorrNewTaskld, vslcCorrNewTaskld, vslzCorrNewTaskld	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to <code>VSL_STATUS_OK</code> if the task is created successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each `NewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)). Unlike `NewTask`, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter *dims* is 1. The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

NewTaskX

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vs1sconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vs1dconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vs1cconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vs1zconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vs1scorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vs1dcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vs1ccorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vs1zcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vsldConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslcConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslzConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslsCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vsldCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslcCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslzCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);
```

Input Parameters

Name	Type	Description

status	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each `NewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

Unlike `NewTask`, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `NewTaskX` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see [DeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

The stride parameter `xstride` specifies the physical location of the input data in the array `x`. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every s^{th} element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

NewTaskX1D

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslcconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslscorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslccorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>const int</code>	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>xshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>const int</code>	Defines the length of the input data sequence for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>const int</code>	Defines the length of the input data sequence for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>const int</code>	Defines the length of the output data sequence to be stored in array <i>z</i> . See Data Allocation for more information.
<i>x</i>	FORTRAN 77: <code>REAL*4</code> for real data in single precision flavors, <code>REAL*8</code> for real data in double precision flavors, <code>COMPLEX*8</code> for complex data in single precision flavors, <code>COMPLEX*16</code> for complex data in double precision flavors Fortran 90: <code>REAL (KIND=4) , DIMENSION</code> <code>(*)</code> for real data in single precision flavors,	Pointer to the array containing input data for the first operand vector. See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	<p>FORTTRAN 77: INTEGER*4</p> <p>task(2) for</p> <p>vslsconvnewtaskxld,</p> <p>vsldconvnewtaskxld,</p> <p>vslcconvnewtaskxld,</p> <p>vslzconvnewtaskxld</p> <p>INTEGER*4 task(2) for</p> <p>vsldcorrnewtaskxld,</p> <p>vsldcorrnewtaskxld,</p> <p>vslccorrnewtaskxld,</p> <p>vslzcorrnewtaskxld</p> <p>Fortran 90:</p> <p>TYPE (VSL_CONV_TASK) for</p> <p>vslsconvnewtaskxld,</p> <p>vsldconvnewtaskxld,</p> <p>vslcconvnewtaskxld,</p> <p>vslzconvnewtaskxld</p> <p>TYPE (VSL_CORR_TASK) for</p> <p>vsldcorrnewtaskxld,</p> <p>vsldcorrnewtaskxld,</p> <p>vslccorrnewtaskxld,</p> <p>vslzcorrnewtaskxld</p> <p>C: VSLConvTaskPtr* for</p> <p>vslsConvNewTaskXld,</p> <p>vsldConvNewTaskXld,</p> <p>vslcConvNewTaskXld,</p> <p>vslzConvNewTaskXld</p> <p>VSLCorrTaskPtr* for</p> <p>vsldCorrNewTaskXld,</p> <p>vsldCorrNewTaskXld,</p> <p>vslcCorrNewTaskXld,</p> <p>vslzCorrNewTaskXld</p>	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to <code>VSL_STATUS_OK</code> if the task is created successfully or set to non-zero error code otherwise.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each `NewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter *dims* is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the `NewTaskX1D` constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see [DeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

The [stride parameters](#) *xstride* specifies the physical location of the input data in the array *x* and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is *s*, then only every *s*th element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

Task Editors

Task editors in convolution and correlation API of the Intel MKL are routines intended for setting up or changing the following task parameters (see [Table 10-14](#)):

- `mode`
- `internal_precision`
- `start`
- `decimation`.

For setting up or changing each of the above parameters, a separate routine exists.

NOTE. Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

After applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and will go through the full commitment process again during the next execution or copy operation. This is motivated by the fact that the currently stored work data computed during the last commitment process may become invalid with respect to new parameter settings. For more information about task commitment, see [Overview](#).

[Table 10-17](#) lists available task editors.

Table 10-17 Task Editors

Routine	Description
SetMode	Changes the value of the parameter <code>mode</code> for the operation of convolution or correlation.
SetInternalPrecision	Changes the value of the parameter <code>internal_precision</code> for the operation of convolution or correlation.
SetStart	Sets the value of the parameter <code>start</code> for the operation of convolution or correlation.
SetDecimation	Sets the value of the parameter <code>decimation</code> for the operation of convolution or correlation.

NOTE. You can use the `NULL` task pointer in calls to editor routines. In this case, the routine will be terminated and no system crash will occur.

SetMode

Changes the value of the parameter `mode` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetmode(task, newmode)
status = vslcorrsetmode(task, newmode)
```

C:

```
status = vslConvSetMode(task, newmode);
status = vslCorrSetMode(task, newmode);
```

Input Parameters

Name	Type	Description
<code>task</code>	<p>FORTRAN 77: INTEGER*4 <code>task(2)</code> for <code>vslconvsetmode</code> INTEGER*4 <code>task(2)</code> for <code>vslcorrsetmode</code></p> <p>Fortran 90: TYPE(VSL_CONV_TASK) for <code>vslconvsetmode</code> TYPE(VSL_CORR_TASK) for <code>vslcorrsetmode</code></p> <p>C: VSLConvTaskPtr for <code>vslConvSetMode</code> VSLCorrTaskPtr for <code>vslCorrSetMode</code></p>	Pointer to the task descriptor.
<code>newmode</code>	<p>FORTRAN 77: INTEGER</p> <p>Fortran 90: INTEGER</p>	New value of the parameter <code>mode</code> .

Name	Type	Description
	C: <code>const int</code>	

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: <code>INTEGER</code> Fortran 90: <code>INTEGER</code> C: <code>int</code>	Current status of the task.

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

Table 10-18 Values of *mode* parameter

Value	Purpose
<code>VSL_CONV_MODE_FFT</code>	Compute convolution by using fast Fourier transform.
<code>VSL_CORR_MODE_FFT</code>	Compute correlation by using fast Fourier transform.
<code>VSL_CONV_MODE_DIRECT</code>	Compute convolution directly.
<code>VSL_CORR_MODE_DIRECT</code>	Compute correlation directly.
<code>VSL_CONV_MODE_AUTO</code>	Automatically choose direct or Fourier mode for convolution.
<code>VSL_CORR_MODE_AUTO</code>	Automatically choose direct or Fourier mode for correlation.

SetInternalPrecision

Changes the value of the parameter `internal_precision` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetinternalprecision(task, precision)
status = vslcorrsetinternalprecision(task, precision)
```

C:

```
status = vslConvSetInternalPrecision(task, precision);
status = vslCorrSetInternalPrecision(task, precision);
```

Input Parameters

Name	Type	Description
<code>task</code>	<p>FORTRAN 77: INTEGER*4 <code>task(2)</code> for <code>vslconvsetinternalprecision</code></p> <p>INTEGER*4 <code>task(2)</code> for <code>vslcorrsetinternalprecision</code></p> <p>Fortran 90:</p> <p>TYPE(VSL_CONV_TASK) for <code>vslconvsetinternalprecision</code></p> <p>TYPE(VSL_CORR_TASK) for <code>vslcorrsetinternalprecision</code></p> <p>C: VSLConvTaskPtr for <code>vslConvSetInternalPrecision</code></p> <p>VSLCorrTaskPtr for <code>vslCorrSetInternalPrecision</code></p>	Pointer to the task descriptor.

Name	Type	Description
<i>precision</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>const int</code>	New value of the parameter <i>internal_precision</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: <code>int</code>	Current status of the task.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The routine changes the value of the parameter *internal_precision* for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for *internal_precision* is assigned by a task constructor and set to either “single” or “double” according to the particular flavor of the constructor used.

Changing the *internal_precision* can be useful if the default setting of this parameter was “single” but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the *internal_precision* input parameter are as follows:

Table 10-19 Values of *internal_precision* Parameter

Value	Purpose
<code>VSL_CONV_PRECISION_SINGLE</code>	Compute convolution with single precision.
<code>VSL_CORR_PRECISION_SINGLE</code>	Compute correlation with single precision.
<code>VSL_CONV_PRECISION_DOUBLE</code>	Compute convolution with double precision.

Value	Purpose
VSL_CORR_PRECISION_DOUBLE	Compute correlation with double precision.

SetStart

Changes the value of the parameter `start` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetstart(task, start)
status = vslcorrsetstart(task, start)
```

C:

```
status = vslConvSetStart(task, start);
status = vslCorrSetStart(task, start);
```

Input Parameters

Name	Type	Description
<code>task</code>	<p>FORTRAN 77: INTEGER*4 <code>task(2)</code> for <code>vslconvsetstart</code></p> <p>INTEGER*4 <code>task(2)</code> for <code>vslcorrsetstart</code></p> <p>Fortran 90: TYPE(VSL_CONV_TASK) for <code>vslconvsetstart</code></p> <p>TYPE(VSL_CORR_TASK) for <code>vslcorrsetstart</code></p> <p>C: VSLConvTaskPtr for <code>vslConvSetStart</code></p>	Pointer to the task descriptor.

Name	Type	Description
	VSLCorrTaskPtr for vslCorrSetStart	
<i>start</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: const int[]	New value of the parameter <i>start</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The routine sets the value of the parameter *start* for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, *start* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *start* is undefined and this parameter is not used. Therefore the only way to set and use the *start* parameter is via assigning it some value by one of the `SetStart` routines.

SetDecimation

Changes the value of the parameter `decimation` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetdecimation(task, decimation)
status = vslcorrsetdecimation(task, decimation)
```

C:

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

Input Parameters

Name	Type	Description
<code>task</code>	<p>FORTRAN 77: INTEGER*4 <code>task(2)</code> for <code>vslconvsetdecimation</code></p> <p>INTEGER*4 <code>task(2)</code> for <code>vslcorrsetdecimation</code></p> <p>Fortran 90: TYPE(VSL_CONV_TASK) for <code>vslconvsetdecimation</code></p> <p>TYPE(VSL_CORR_TASK) for <code>vslcorrsetdecimation</code></p> <p>C: VSLConvTaskPtr for <code>vslConvSetDecimation</code></p> <p>VSLCorrTaskPtr for <code>vslCorrSetDecimation</code></p>	Pointer to the task descriptor.

Name	Type	Description
<i>decimation</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: const int[]	New value of the parameter <i>decimation</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The routine sets the value of the parameter *decimation* for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if *decimation* = *d* > 1, only every *d*-th element of the mathematical result is written to the output array *z*. In a multidimensional case, *decimation* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Therefore the only way to set and use the *decimation* parameter is via assigning it some value by one of the `SetDecimation` routines.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the supplied user data for input vectors.

Once created and adjusted, the task can be executed multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL implementation of the convolution and correlation API provides two different forms of execution routines: a general form and an X-form. General form executors use the task descriptor created by the general form constructor and expect to get two source data arrays x and y on input. Alternatively, X-form executors use the task descriptor created by the X-form constructor and expect to get only one source data array y on input because the first array x has been already specified on the construction stage.

When the task is executed for the first time, the execution routine includes task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

For each execution routine there is also an associated one-dimensional version which exploits the algorithmic and computational benefits provided by the simplicity of the data structures for one-dimensional case.

NOTE. You can use the `NULL` task pointer in calls to execution routines. In this case, the routine will be terminated and no system crash will occur.

If the task is executed successfully, the execution routine returns zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`,
- if the task descriptor is corrupted,
- if calculation has failed for some other reason.

NOTE. Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Table 10-20 Task Execution Routines

Routine	Description
<code>Exec</code>	Computes convolution or correlation for a multidimensional case.
<code>Exec1D</code>	Computes convolution or correlation for a one-dimensional case.
<code>ExecX</code>	Computes convolution or correlation as X-form for a multidimensional case.

Routine	Description
ExecX1D	Computes convolution or correlation as X-form for a one-dimensional case.

Exec

Computes convolution or correlation for multidimensional case.

Syntax

Fortran:

```
status = vslsconvexec(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);
```

Input Parameters

Output Parameters

Name	Type	Description
<i>z</i>	FORTRAN 77: REAL*4 for vslsconvexec and vslscorrexec, REAL*8 for vsldconvexec and vsldcorrexec, COMPLEX*8 forvslcconvexec and vslccorrexec, COMPLEX*16 forvslzconvexec and vslzcorrexec	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	Fortran 90: REAL (KIND=4) , DIMENSION (*) for vslsconvexec and vslscorrexec, REAL (KIND=8) , DIMENSION (*) for vsldconvexec and vsldcorrexec, COMPLEX (KIND=4) , DIMENSION (*) forvslcconvexec and vslccorrexec, COMPLEX (KIND=8) , DIMENSION (*) for vslzconvexec and vslzcorrexec C: const float[] for vslsConvExec and vslsCorrExec, const double[] for vsldConvExec and vsldCorrExec, const MKL_Complex8[] for vslcConvExec and vslcCorrExec, const MKL_Complex16[] for vslzConvExec and vslzCorrExec	
<i>status</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each of the `Exec` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTask` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

The stride parameters `xstride`, `ystride`, and `zstride` specify the physical location of the input and output data in the arrays `x`, `y`, and `z`, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `zstride` is `s`, then only every s^{th} element of the array `z` will be used to store the output data. The stride value must be positive or negative but not zero.

Exec1D

Computes convolution or correlation for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvexecd(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexecd(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexecd(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexecd(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexecd(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexecd(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexecd(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexecd(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

<i>status</i>	<div>FORTRAN 77: INTEGER Fortran 90: INTEGER C: int</div>	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each of the `Exec1D` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter `dims` is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTask1D` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

ExecX

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexec(task, y, ystride, z, zstride)
status = vsldconvexec(task, y, ystride, z, zstride)
status = vslcconvexec(task, y, ystride, z, zstride)
status = vslzconvexec(task, y, ystride, z, zstride)
status = vslscorexec(task, y, ystride, z, zstride)
status = vsldcorexec(task, y, ystride, z, zstride)
status = vslccorexec(task, y, ystride, z, zstride)
status = vslzcorexec(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslcConvExecX(task, y, ystride, z, zstride);
status = vslzConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vslcCorrExecX(task, y, ystride, z, zstride);
status = vslzCorrExecX(task, y, ystride, z, zstride);
status = vsldCorrExecX(task, y, ystride, z, zstride);
```

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslsconvexecx, vsldconvexecx, vslcconvexecx, vslzconvexecx INTEGER*4 task(2) for vslscorreexecx, vsldcorreexecx, vslccorreexecx, vslzcorreexecx Fortran 90: TYPE (VSL_CONV_TASK) for vslsconvexecx, vsldconvexecx, vslcconvexecx, vslzconvexecx TYPE (VSL_CORR_TASK) for vslscorreexecx, vsldcorreexecx, vslccorreexecx, vslzcorreexecx C: VSLConvTaskPtr for vslsConvExecX, vsldConvExecX, vslcConvExecX, vslzConvExecX VSLCorrTaskPtr for vslsCorrExecX, vsldCorrExecX, vslcCorrExecX, vslzCorrExecX	Pointer to the task descriptor.

Name	Type	Description
<code>x ,y</code>	<p>FORTRAN 77: REAL*4 for <code>vslsconvexecx</code> and <code>vsldconvexecx</code>, REAL*8 for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code>, COMPLEX*8 for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code>, COMPLEX*16 for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code></p> <p>Fortran 90: REAL (KIND=4) , DIMENSION (*) for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code>, REAL (KIND=8) , DIMENSION (*) for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code>, COMPLEX (KIND=4) , DIMENSION (*) for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code>, COMPLEX (KIND=8) , DIMENSION (*) for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code></p> <p>C: const float[] for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code>,</p>	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	<code>const double[]</code> for <code>vsldConvExecX</code> and <code>vsldCorrExecX</code> , <code>const MKL_Complex8[]</code> for <code>vslcConvExecX</code> and <code>vslcCorrExecX</code> , <code>const MKL_Complex16[]</code> for <code>vslzConvExecX</code> and <code>vslzCorrExecX</code>	
<code>ystride</code> <code>,zstride</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: <code>const int[]</code>	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<code>z</code>	FORTRAN 77: <code>REAL*4</code> for <code>vslsconvexecx</code> and <code>vsldconvexecx</code> and <code>vsldcorrexecx</code> , <code>REAL*8</code> for <code>vsldconvexecx</code> and <code>vsldcorrexecx</code> , <code>COMPLEX*8</code> for <code>vslcconvexecx</code> and <code>vslccorrexecx</code> , <code>COMPLEX*16</code> for <code>vslzconvexecx</code> and <code>vslzcorrexecx</code>	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	Fortran 90: REAL(KIND=4) , DIMENSION(*) for vslsconvexecx and vslscorrexecx, REAL(KIND=8) , DIMENSION(*) for vsldconvexecx and vsldcorrexecx, COMPLEX(KIND=4) , DIMENSION (*) for vslcconvexecx and vslccorrexecx, COMPLEX(KIND=8) , DIMENSION (*) for vslzconvexecx and vslzcorrexecx C: const float[] for vslsConvExecX and vslsCorrExecX, const double[] for vsldConvExecX and vsldCorrExecX, const MKL_Complex8[] for vslcConvExecX and vslcCorrExecX, const MKL_Complex16[] for vslzConvExecX and vslzCorrExecX	
<i>status</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each of the `ExecX` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array `x`.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTaskX` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.
